The governor appoints a mixed board of medical registration and examination representing the different schools of practice. "All applicants for license shall file with the secretary of the board a written application on a form prescribed by the board, verified by oath, and furnish satisfactory proof that he is more than 21 years of age, and is of good moral character. In the application, as a condition of admission to the examination, he shall produce either of the following credentials: a diploma from a reputable college granting the degree A.B., B.S., or equivalent degree; a diploma from a normal school, high school or seminary, legally constituted, issued after four years' of study; a teacher's permanent or life certificate; a medical student's certificate of examination for admission by any state board; a student's certificate of examination for admission to the freshman class of a reputable literary or scientific college; or a certificate of his having passed an examination conducted under the direction of the state board of medical registration and examination by certified examiners, none of whom shall be either directly or indirectly connected with a medical college: said examinations to be held simultaneously in Cincinnati, Cleveland, Columbus and Toledo and the questions submitted to be uniform at such places; and has either received a diploma from some legally chartered medical institution in the United States in good standing at the time of issuing such diploma, as defined by the board; or a diploma or license approved by the board, which has conferred the full right to practice all branches of medicine or surgery in some foreign country, with the application, the applicant shall present his diploma or license, as above defined, and accompanying the same, shall file his affidavit duly attested, stating that he is the person named in the diploma or license, and is the lawful possessor of the same, and giving his age, residence, and the college or colleges at which he obtained his medical education, the time spent in each college, the time spent in the study of medicine, and such other facts as the board may require; if engaged in the practice of medicine, the applicant shall state the period during which, and the place at which, he has been engaged in the practice of medicine or surgery."

Each applicant shall be examined in anatomy, physiology, pathology, chemistry, and materia medica and therapeutics, the principles and practice of medicine, surgery, obstetrics, and such other subjects as the board may require. The applicant shall be examined in materia medica and therapeutics and the principles and practice of medicine, of the school of medicine in which he desires to practice, by the member or members of the board representing such school. An affirmative vote of not less than five members shall be required to authorize the issuance of a certificate. The fee for examination shall be $25, which shall not be returned in case of failure to pass such examination, but the applicant may within a year after such failure, present himself and be examined again without the payment of an additional fee. The board may, in its discretion, dispense with an examination in the case of a physician or surgeon duly authorized to practice medicine or surgery in any other state, territory, or the District of Columbia, who may desire to change his residence to Ohio, and who makes application on a form to be prescribed by the board, accompanied by a fee of $50 and presents a certificate or license issued after an examination by the medical board of such state, territory, or the District of Columbia, accorded only to applicants from states, territories and districts whose laws demand qualifications of equal grade with those required in Ohio; but such examination shall not be dispensed with unless under the law and regulations of the state, territory, or the District of Columbia, equal rights and privileges are accorded to physicians and surgeons of Ohio, holding the certificate of the board, who may desire to remove to, and practice in such state, territory, or the District of Columbia. Certificates must be filed with the probate judge of the county in which he resides, for record. Midwives also have to be examined for license; fee $10.

"Any person shall be regarded as practicing medicine or surgery or midwifery within the meaning of this act, who shall use the words or letters, 'Dr.,' 'Doctor,' 'Professor,' 'M.D.,' 'M.B.,' or any other title in connection with his name, which in any way represents him as engaged in the practice of medicine or surgery or midwifery, in any of its branches, or who shall prescribe, or who shall recommend for a fee for like use any drug or medicine, appliance, operation or treatment, of whatever nature, for the cure or relief of any wound, fracture or bodily injury, infirmity or disease. The use of any of the above mentioned words or letters or titles in such connection, and under such circumstances as to induce the belief that the person who uses them is engaged in the practice of medicine or surgery or midwifery in any of its branches, shall be deemed and accepted as *prima facie* proof of an intent on the part of such person to represent himself as engaged in the practice of medicine or surgery or midwifery."

As usual, emergency practice, domestic remedies, government officials, consultants from outside the state, etc., are exempted from the provisions of the law. Osteopathic graduates passing satisfactory examinations in anatomy, physiology, chemistry and physical diagnosis are allowed to practice their massage, but forbidden to give drugs or perform surgery. Secretary, state board of registration and examination, Dr. Frank Winders, Columbus. Regular meetings of the board at Columbus on the first Tuesday in January, April, July and October. Examinations will begin on the second Tuesday of June and December and will continue for three days. Examinations will not be held at any other time except as stated above.

OKLAHOMA.

The territorial board of health has among its functions to regulate admissions to practice. Only graduates of reputable recognized colleges are given certificates without examination. Others must pass a satisfactory examination and prove that they have been five years engaged in reputable practice. The board can refuse examination to those it considers unfit. The fee for license on diploma is $2, for examination $30, not returnable. All examinations are in writing and must show qualifications equal to those required for graduation in respectable medical colleges. No person can practice if not of good moral character or if he is an habitual drunkard. Board meets for examination every three months; next meeting, December 5.

President board of health, Dr. E. E. Cowdrick, Enid; secretary, Dr. Grant Cullimore, Oklahoma City.

OREGON.

The governor appoints the state board of medical examiners, consisting of three regular, one homeopathic and one eclectic physician. The law provides that: Every person, except those licensed under former laws, desiring to practice medicine and surgery, or either of them, in any of their or its branches in this state, shall make a written application to the board for a license, which application shall be supported and accompanied by an affidavit setting forth the actual time spent by the applicant in the study of medicine and surgery, and when, whether such study was in an institution of learning, and if so, the name and location thereof, and if not in such (an) institution, where and under whose tutorship such study was prosecuted, the time said applicant shall have been engaged in the actual practice, if at all, of medicine and surgery, or either of them, and where the applicant was located during the time of such practice, and the age of the applicant at the time of making application; such application and affidavit to be filed and preserved in the office of the secretary of said board. Such applicant at the time and place designated by said board; or at the regular meeting of said board, shall submit to an examination in the following branches, to-wit: Anatomy, physiology, chemistry, materia medica, therapeutics, practice of medicine, surgery, obstetrics, diseases of women, medical jurisprudence and such other branches as the board shall deem advisable. Such examination shall be both scientific and practical and of sufficient severity to test the candidate's fitness to practice medicine and surgery, and by written or printed, or partly written or partly printed, questions and answers, and the same shall be filed and preserved of record in the office of the secretary of said board. After a satisfactory examination the board shall grant a license to the applicant to practice medicine and surgery in the State of Oregon, which can only be granted by the consent of not less than four members of the board. The board may refuse or revoke a license for unprofessional or dishonorable conduct, subject, however, to the right of such applicant to appeal from the decision of said board refusing or revoking such license. The words "unprofessional" or "dishonorable conduct" as used in the act, are defined in the same words as in the California practice law, with the addition that "the employment of what are popularly known as 'cappers' or 'steerers'" is also included under these heads. Fee for examination is $10.

"Any person shall be regarded as practicing within the meaning of this act who shall append the letters, 'M.D.' or 'M.B.' to his or her name, or, for a fee, prescribe, direct or recommend for the use of any person any drug or medicine or agency for the treatment, care or relief of any wound, fracture or bodily injury, infirmity or disease: Provided, however, the act shall not apply to dentists in the practice of their dental profession."

Board meets at Portland for examination on first Tuesday of January and July. Secretary, board of medical examiners, Dr. Byron E. Miller, Portland.

PENNSYLVANIA.

The medical council, a body composed of the lieutenant-governor, the attorney-general, the secretary of internal affairs, the superintendent of public instruction, the president of the state board of health and the presidents of three state boards of medical examiners, have the supervision of the examination of candidates to practice medicine in the state. These, except the secretary and treasurer, serve without pay. There are also appointed by the governor three boards of medical examiners of seven members each, representing the several medical societies of the State of Pennsylvania, the regular, homeopathic and eclectic, from lists furnished by them. The fees for examinations, after payment of current expenses, are apportioned pro rata to the members of the several examining boards according to the number of candidates examined by each These boards submit to the medical council a list of questions from which the council makes up the questions for each examination The examinations, which are in writing, are conducted by the respective boards and the results transmitted to the council, which issues the licenses to those who have successfully passed.

"A preliminary examination shall be required from all candidates for medical license in the following branches, to-wit, arithmetic, grammar, geography, orthography, American history, physiology and hygiene, and English composition. The diploma of a college, diploma of an academy, seminary, normal school, or high school; or a teacher's permanent certificate: or a student's certificate of examination for admission to the freshman class in a literary college, shall be accepted in lieu of such examination." Preliminary examinations are held under direction of the medical council in June preceding the examinations by the state examining boards, and in October after the opening of the medical colleges, at Philadelphia and in Western Pennsylvania.

Section 13 of the medical practice law reads: "From and after the first day of July, 1894, any person not heretofore authorized to practice medicine and surgery in this state, and desiring to enter upon such practice, may deliver to the secretary of the medical council, upon the payment of a fee of $25, a written application for license, together with satisfactory proof that the applicant is more than 21 years of age, is of good moral character, and has obtained a competent common school education, and has received a diploma conferring the degree of medicine from some legally incorporated medical college of the United States, or a diploma or license conferring the full right to practice all the branches of medicine and surgery in some foreign country. Applicants who shall have received their degree in medicine after the first day of July, 1894, must have pursued study of medicine for at least three years, including three regular courses of lectures, in different years, in some legally incorporated medical college or colleges, prior to granting of said diploma, or foreign license, and after the first day of July, 1895, such applicants must have pursued the study of medicine for at least four years, including three regular courses of lectures, in different years, in some legally incorporated medical college, or colleges, prior to the granting of said diploma or foreign license. Such proof shall be made, if required, upon affidavit. Upon the making of said payment and proof, the medical council, if satisfied with the same, shall issue to said applicant an order for examination before such one of the state boards of medical examiners as the applicant for license may select. In case of failure at any such examination the candidate, after the expiration of six months and within two years, shall have the privilege of a second examination by the same board to which application was first made, without the payment of an additional fee; and it is provided further, that applicants examined and licensed by the state board of medical examiners or state boards of health of other states, on payment of a fee of $15 to the medical council, and on filing in the office of the medical council a copy of such license certified by the affidavit of the president and secretary of such board showing also that the standard of acquirements adopted by the said state board of medical examiners or state board of health, is substantially the same, as is provided by sections 11, 12 and 13 of this act, shall without further examination receive a license conferring on the holder thereof all the rights and privileges provided by sections 14 and 15 of this act."

Licenses must be registered with the prothonotary of the court of common pleas and in the county of residence; fee $1. The law contains a reciprocity clause, but only certificates of New York are accepted and (until recently, New Jersey). The usual exemptions of government officers, outside consultants, border practice, etc., are made in the law. Secretary, medical council, Hon. James W. Latta, Harrisburg.

RHODE ISLAND.

Law of 1895, Section 3: "Authority to practice medicine under this law shall be a certificate from the state board of health, and said board shall upon application issue a certificate to any reputable physician who is practicing, or who desires to begin the practice of medicine or surgery in this state, who possesses any of the following qualifications: 1. A diploma from a reputable and legally chartered medical college, endorsed as such by the state board of health. 2. Satisfactory evidence from the person claiming the same that such person was reputably and honorably engaged in the practice of medicine or surgery in this state prior to January 1, 1892. Any person not qualified as hereinbefore provided, before practicing medicine or surgery in this state, shall present himself before said board of health and submit himself to such examination as said board may require. Said board shall examine person presenting himself and if the examination is satisfactory, shall issue its certificate as hereinbefore provided. Provided, any person so presenting himself shall pay to the board the sum of $10 for each examination, and said fee shall in no case be returned, and shall be applied to pay the expenses of the board of health. Applicants may present their credentials by mail or proxy, and the board shall issue its certificates to such applicants as are entitled thereto as though the applicant were present. All certificates shall be signed by the president and secretary, and attested by the seal of the board, and not more than $2 will be charged for any certificate.

"Section 4. Nothing in this law shall be so construed as to authorize any itinerant doctor to register or to practice medicine in any part of this state.

"Section 5. The state board of health may refuse to issue the certificate provided for in section three of this article, to any individual guilty of grossly unprofessional conduct of a character likely to deceive or defraud the public, and it may after due notice and hearing revoke such certificate for like cause. In all cases of refusal or revocation the applicant may appeal to the appellate division of the supreme court, who may affirm or overrule the decision of the board, and its decision shall be final." Sections 7 and 8 provide for prosecution and punishment for illegal practice in the state. Section 8 says: "To open an office for such purpose, or to announce to the public in any other way a readiness to practice medicine or surgery in this state, shall be to engage in the practice of medicine within the meaning of this law." Licenses must be registered with the town or city clerk.

Supplementary examinations in the subjects of surgery, theory and practice of medicine and in obstetrics, including gynecology, are required of graduates from schools which do not give four full years of eight months in each year as a requisite for issuance of diploma. Also of those from schools which admit to advanced standing in the second year, applicants who may be graduates of dental, veterinary or pharmaceutical schools, and which in this way permit the student to go through the school in three years. Schools which admit to advanced standing applicants who have taken a course equal to the first year of the college and who are examined before entrance into the second year, are considered as in good standing and no examination is required. Full examination is required from schools which are located in a city of less than 50,000 inhabitants. The examination is upon seven subjects and on practically the same as those recommended by the Conference of Medical Examining and Licensing Boards of New England. Board meets for examination at State House, Providence, on the first Thursday in the months of January, April, February and October. Secretary, state board of health, Dr. Gardner T. Swarts, Providence.

SOUTH CAROLINA.

The authorization to practice medicine is in the hands of the state board of medical examiners, one from each congressional district elected by the South Carolina Medical Association and

commissioned by the governor. The board holds its meetings at the state house in Columbia on the third Tuesday of May of each year, at which time all applicants for a license to practice medicine in this state must exhibit a diploma from a recognized medical college, a certificate of moral character, and must pass a satisfactory written examination on all branches of medicine. The chairman and secretary of the board are allowed to grant a temporary license to practice medicine until the meeting of the board in May of each year, at which time the applicant must come up for the regular written examination above mentioned. The applicant for a temporary license will be expected to stand an oral examination on all the branches of medicine. Temporary license fee $2.50.

Physicians moving into the state from other states are subject to the same laws as those who are residents, irrespective of any examinations held previous to their change of location. No one is allowed to practice medicine in this state without either a temporary license or a regular license as prescribed by law. The questions at the examination are similar in character to those given by a first-class medical college. Examinations are held under the following heads 1, anatomy, general and regional; 2, physiology and histology; 3, chemistry, practical uranalysis, medical physics and hygiene; 4, materia medica, therapeutics and toxicology; 5, surgery and surgical pathology; 6, practice and diseases of children; 7, obstetrics and gynecology. An average of at least 75 per cent. on the whole list of subjects shall be attained by each applicant, and he shall not make less than 60 per cent. on any one branch. A fee of $5 will be required of each applicant who is granted a license, said fee to be paid to the secretary before examination is entered upon. The fee will be refunded to those failing to pass. Licenses must be recorded with clerk of county court. It would appear that the graduates of medical colleges in South Carolina are by recent legislation (1900-1901) exempt not only from examinations but also from all other provisions of the law, including fees, application for license, etc. All that appears to be required, according to the opinion of the attorney-general, is that satisfactory evidence be given the board that the college has an advertised four years' course and that they have met the requirements in the judgment of the faculty. This exemption does not apply to holders of diplomas received before the adoption by the college of the four years' course.

United States government officials and consultants from without the state meeting licensed physicians, dentists and midwives are also exempted. Appeal to the governor from the action of the board is provided for, and he can order a special examination. Secretary, state board of medical examiners, Dr. S. C. Baker, Sumter.

SOUTH DAKOTA.

Law of 1893: Section 5. "The board of health of this state is hereby constituted a board of public examiners ex-officio for the purpose of examining and licensing physicians to practice medicine in this state and any person who is a graduate of a lawful medical college who has attended three full courses of medical lectures of six months each, no two full courses within the same year, and who is of good moral character, and is not an habitual drunkard, shall upon proof of such facts to the superintendent of the state board of health as said board shall require, and on payment of a license fee of $5, which shall be applied as a part of the superintendent's salary, receive from said superintendent of the state board of health a license certifying the applicant to be a practicing physician and qualified for such as prescribed by this section; which license shall be recorded in the office of the registrar of deeds in the county where such practicing physician resides. Provided that the requirements of the three courses of lectures shall not apply to those who have graduated prior to the passage of this act." Licenses may be revoked after due hearing by the board for intemperance, immorality or gross unprofessional conduct. It is made the duty of the state attorneys to prosecute for violations of the law. The usual exemptions are made.

Secretary, state board of health, Dr. A. E. Clough, Madison.

TENNESSEE.

The latest law of Tennessee approved April 22, 1901, provides for a state board of medical examiners by whom all applicants for license must be examined. The board consists of six members who must be graduated physicians of not less than six years' practice, two of whom must reside in each grand division of the state, the three schools of medicine being represented as follows: regulars, four; homeopaths and eclectics, each one. The appointments are made by the governor.

Section 5 provides for a regular meeting of the board once each year in the city of Nashville, "so long as the period of temporary licenses herein after provided for shall continue, and shall thereafter be held semi-annually in the said city of Nashville; but special meetings may be held oftener upon the call of the president."

Section 6 provides that persons desiring to obtain a license must make application in writing to the board accompanied by the examination fee (($10 for permanent license, $5 for temporary license) and by $5 for certificate of license with satisfactory proof that the applicant is of good moral character. "When these preliminary requirements are satisfied, the applicant shall then present himself before the board for examination upon the following branches, viz: Anatomy, physiology, chemistry, pathology, surgery, obstetrics, materia medica and practice; but the member or members of the board representing each separate school of medicine, shall have the right to examine all applicants of that school in the branches peculiar to the teachings of that school, and the board shall accept the grade placed by such member or members upon such special branches. Provided, however, that graduates of any reputable medical college in the State of Tennessee shall until June 1, 1902, be granted a certificate of license by said board, without reference to the number or length of terms attended and without the examination herein above prescribed; but this provision shall cease and determine after June 1, 1902.

"Section 7. That the two members of said board in each grand division of the state shall at such time or times as the board may direct meet at some convenient point in their respective divisions for the purpose of examining applicants for permanent licenses. Such meetings shall be held at stated periods, and the questions to be propounded upon such examinations shall have been determined upon in advance by the board, and shall be identical in each division and such examinations shall be held on the same day in each division, and under uniform rules and regulations to be adopted by the board. The examination papers shall be sealed up and carried to Nashville to the annual meeting of the board at which time they shall be examined, graded, and passed upon by the board in annual session, and the results declared and certificates issued to those entitled to receive them. The board or any of its respective sections may at the option of the members supplement such written examination by an oral examination, and the recorded value of such oral examination may be given such importance as each member of the board sees fit.

"Section 8. Be it further enacted, that if the applicant for examination shall thereupon be found worthy and competent by the board, it shall issue to him a certificate of permanent license in accordance with the facts in each case to practice medicine or surgery in this state.

"Section 9. Be it further enacted, that in order to prevent delay and inconvenience the two members of the board of any grand division of the state may grant a certificate of temporary license to any applicant who is permanently located as a resident of some designated place in that division of the state, upon satisfactory evidence to them that such applicant possesses the qualification herein above required, and upon examination by them of such applicant in the subjects named in section 6 of this act, (Fee for examination for temporary license, $5, and fee for license, $1; total $6) and make report thereof to the next regular meeting of the board, such temporary license shall not continue in force longer than the conclusion of the next regular meeting of the board, and shall in no case be granted within six months after the applicant has been refused a certificate of license by the board, provided that after Jan. 1, 1903, no certificates of temporary license shall be issued."

Sections 12 and 13 prescribe recording of license with county court clerk prior to commencing practice and on changes of residence from one county to another and the keeping of the records of the same by the clerk. Section 15 prescribes for revocation of license for unprofessional or dishonorable conduct, which is defined in section 16.

Section 16 defines the words unprofessional or dishonorable conduct as used in Section 15 of this act in the same words as in the California law, except that with habitual intemperance the "excessive use of narcotics" is added. Section 17 prohibits itinerant or other nostrum venders. Section 18 prescribes penalties for illegal practice. Section 19. "Be it further enacted that any person shall be regarded as practicing medicine within the meaning of this act who shall treat or profess to treat, operate on, or prescribe for any physical ailment or any physical injury to or deformity of another.". The law is specified not to apply to those usually exempted, or to osteopaths not giving or using medicine in their practice, nor to opticians nor to christian scientists. Section 21 provides for the grand jury to have inquisitorial power in case of violations of the act. Section 22 disqualifies the board for issuing any license contrary to its provisions, and Section 23 repeals former law and amendments contrary to this act.

Secretary, state board of medical examiners, Dr. T. J. Happel, Trenton.

TEXAS.

The new law that went into effect July 9, 1901, provides for the appointment by the governor of three boards of medical examiners, regular, eclectic and homeopathic, from lists furnished by the respective state societies and that all persons desiring to practice as physicians or professional midwives, and not qualified under earlier laws, must pass an examination.

"Section 6. In case any applicant shall fail to pass a satisfactory examination he or she shall not be permitted to stand any further examination within one year thereafter, and in no event shall an applicant who stands rejected by one of said boards be examined or licensed by either of the other boards. If an applicant desires to practice a system not represented by any of the boards hereby established, he or she may elect for himself or herself the board before which he or she will appear for examination; provided, that no applicant shall be rejected because of his or her adherence to any particular school of medicine or system of practice, nor on account of his or her views as to the method of treatment, and cure of disease; and provided further, when in the opinion of the presidents of the boards any applicant had been unavoidably prevented from appearing before the board at their regular meeting, said president shall, upon notification, appoint a committee of three members to examine such applicant and if the examination be satisfactory, notify the secretary, who shall issue him or her a temporary certificate, which shall have the same force and effect as though granted by the full board until the applicant shall have the opportunity to appear before the board at its next regular meeting, when said temporary certificate shall become void. No applicant shall be admitted to examination who can not submit satisfactory evidence that he or she is more than 21 years of age, and is of good moral character. Applications for license must be made in writing and presented to the president or secretary of the board before which the applicant desires to appear and must be accompanied with a fee of $15; provided when the applicant desires to practice midwifery alone, the fee shall be $5.

"Section 8. All persons who may change their residence to the State of Texas, on filing a true copy of a license granted by the board of medical examiners of another state or territory certified by the affidavits of the president and secretary of said board with satisfactory proof of the genuineness of the same, and showing that the standard of requirements of the medical laws of said state or territory and that adopted by said board of medical examiners are equal to that provided for in this act, and who, on the payment of the usual fee of $15, may be registered and receive a license from the board of medical examiners of Texas to practice in this state.

"Section 9. Any person shall be regarded as practicing medicine or surgery within the meaning of this act who shall profess publicly to be a physician or surgeon and shall offer for practice as such or prescribe for those needing medical and surgical aid,

and shall charge or receive therefor money or other compensation. This act shall be so construed as to include persons not pretending to be physicians who offer for sale publicly on the streets or other public places remedies not manufactured and compounded within this state, which they recommend for the cure of disease. Consultants, government officials acting as such, etc., are exempted.

"Section 10. The applicant shall be examined in the following branches: Anatomy, physiology, chemistry, materia medica, therapeutics, histology, pathology, practice of medicine, surgery (including diseases of the eye, ear, nose and throat), obstetrics, gynecology, hygiene and medical jurisprudence."

Secretary, state board of medical examiners, Dr. M. M. Smith, Austin.

Regular meetings of the examining boards are specified to be held twice a year, at places duly advertised.

UTAH.

The state board of medical examiners consisting of seven members "who shall be representatives of the various recognized schools of medicine" is appointed by the governor.

"The board shall have power to issue certificates to any person who furnishes satisfactory proof of having received a degree or diploma from a chartered medical college in good standing and who shall pass a satisfactory examination before the board. The board shall issue two forms of certificates or licenses, one for persons holding such a degree or diploma who have been examined and favorably passed upon by the board, and another for persons desiring to practice obstetrics under the provisions of section 1737. Certificates and licenses shall be signed by all members of the board granting them." The fee for the examination provided above shall be $15, which shall be paid to the treasurer of the board of examiners.

"No non-graduate licensed under the provisions of the acts of the territorial legislature shall, in any way advertise as a doctor, physician or surgeon, but shall, if he advertises at all, do so as a licensed non-graduate practitioner of medicine. The secretary of the board shall enter, without fee, upon the register to be kept by him, the names of all persons to whom certificates are issued as physicians and surgeons.

"Examinations may be made wholly or partially in writing. The board of medical examiners may refuse to issue the certificates provided for in this title to individuals convicted by a court of competent jurisdiction, of any offense involving immoral or dishonorable conduct, the nature of which shall be stated in writing. The board may revoke such certificates for like causes.

"Any person shall be regarded as practicing medicine within the meaning of this title who shall treat, operate upon, or prescribe for any physical ailment of another for a fee, or who shall hold himself out by means of signs, cards, advertisements, or otherwise, as a physician or surgeon; but nothing in this title shall be construed to prohibit services in case of emergency, or the administration of family remedies, nor to prevent medical officers of the United States army from the discharge of their official duties, nor to prohibit visiting physicians in the act of consultation.

"Persons desiring to practice obstetrics in this state shall be entitled to a license upon satisfactorily passing an examination by the state board of examiners and paying to the treasurer thereof a fee of $5; provided, that this section shall not be construed to prevent physicians holding a certificate from practicing obstetrics or to prohibit such service or the acceptance of a fee in case of emergency, or persons practicing obstetrics in communities where there are no licensed practitioners.

"The board of medical examiners shall meet on the first Monday in January, April, July and October of each year, at 10 o'clock a.m., and such other time as the president of the board shall deem necessary. The place of meeting shall be at the state capital. The term 'medical college' in this title shall include colleges in good standing in the states where they exist."

Secretary, board of medical examiners, Dr. R. W. Fisher, Salt Lake City.

VERMONT.

The board of registration in Vermont consists of the board of censors of the respective state medical societies which are authorized to examine and license practitioners of medicine, surgry and midwifery. Any one who offers his services as such or who assumes the title of Doctor must obtain a certificate from such board. Pursuant to Act 112, Laws of Vermont, 1898, the board of censors of the Vermont State Medical Society will require graduates in medicine who apply for a license to practice medicine in the state of Vermont, to pass an examination in anatomy, physiology, materia medica and therapeutics, chemistry, practice of medicine, surgery, obstetrics and pathology. Examinations will be held at Burlington, on the third Wednesday of January, April, July and October of each year. The standard of the colleges is determined by the board. Fee for examination, $5. Licenses must be recorded with the county clerk of the county in which physician practices.

Secretary, state board of censors (representing Vermont State Medical Society), Dr. C. W. Strobill, Rutland.

VIRGINIA.

Virginia has a state board of medical examiners, one from each congressional district, and three at large, from list furnished by Medical Society of Virginia, besides two homeopathic members nominated by the Hahnemann Medical Society of the Old Dominion Law of 1900. The applicant for license "shall produce before said board a diploma, or other satisfactory evidences of his graduation in some medical college, chartered by the state or territory in which the same is situated; provided, that any undergraduate taking a graded course in any regularly chartered medical college shall be entitled to an examination on such branch or branches as he or she may present a certificate from the said college of having passed a satisfactory examination, and having once passed a satisfactory examination on each of such branches before the state board of medical examiners, no further examination shall be required on such branch or branches; but an applicant failing to pass a satisfactory examination on any of such branches, shall not be permitted to be examined on such branch or branches until he or she presents a diploma of graduation as Doctor of Medicine from some regularly chartered college of medicine. When an applicant shall have made an examination satisfactory as to proficiency before the board in session, the president thereof shall grant to such applicant a certificate to that effect. A fee of $10 shall be paid to said board, through such officers or members as it may designate, by each applicant before such examination is had, and in case any applicant shall fail to pass a satisfactory examination, he shall not be permitted to stand any further examination within the next six months thereafter, nor shall he have again to pay the fee prescribed as aforesaid; provided, however, no applicant shall be rejected upon his examination on account of his adherence to any particular school of medicine or system of practice, nor on account of his views as to the method of treatment and care of diseases; and, provided, further, that when, in the opinion of the president of the board, any applicant has been prevented by good cause from appearing before the board, he shall have authority, in his discretion, to grant a special permit to such applicant to practice medicine or surgery until he shall have an opportunity to appear before the board in session for examination, which special permit shall be revocable at the discretion of the president, and in no case shall it entitle the holder thereof to practice after the next regular meeting of said board. The board shall have in their discretion, authority to accept in lieu of examination of an applicant, a diploma or other satisfactory evidence of the graduation of the applicant in some medical college chartered by the state or territory in which the same is situated, and a certificate from the examining board of any other state or territory in which the same is situated, and a certificate from the examining board of any other state or territory of the United States or the District of Columbia, showing that such applicant has passed a satisfactory examination as to his proficiency and obtained a license from said board to practice medicine and surgery in said state, territory or district; provided, that any person who was examined by the state examining board prior to Jan. 1, 1900, and whose fee for such examination was duly paid, but who failed to pass said examination, shall have the right and privilege of taking the examination before the state board notwithstanding the provisions of this act."

"Any person shall be regarded as practicing medicine or surgery for compensation within the meaning of this act, who shall profess publicly to be a physician or surgeon, and shall offer for practice as such, or who shall prescribe for the sick or those needing medical aid and shall receive therefor money or other compensation, directly or indirectly." Section 1752 exempts dentists, midwives, government officers, in the line of their duties, and consultants from without the state.

Secretary state board of medical examiners, Dr. R. S. Martin, Stuart.

WASHINGTON.

The examining board of nine members is appointed by the governor. They must be skilled and learned in the practice and theory of medicine and surgery, and hold office for three years.

Section 3. "Hereafter every person desiring to commence the practice of medicine and surgery, or either of them, in any of its or their branches, in this state shall make a written application to said board for license so to do. Each applicant for such license shall be not less than 21 years of age, shall furnish a certificate of good moral character, and shall be a graduate of some duly authorized medical college now having at least a three years' graded course. Such applicant at the time and place designated by said board, or at the regular meeting of said board, shall submit to an examination in the following branches: Anatomy, physiology, chemistry, histology, materia medica, therapeutics, preventive medicines, practice of medicine and surgery, obstetrics, diseases of women and children, diseases of the nervous system, diseases of the eye and ear, medical jurisprudence, and such other branches as the board shall deem advisable. Said board shall cause such examination to be both scientific and practical, and of sufficient severity to test the candidate's fitness to practice medicine and surgery; which examination shall be by written or printed, or partly written or partly printed questions and answers, and the same shall be filed and preserved of record in the office of the secretary of said board. After examination, if the same be satisfactory, said board shall grant a license to such applicant to practice medicine and surgery in the state of Washington, which said license can only be granted by the consent of not less than five members of said board, except as hereinafter provided, and which said license shall be signed by the president and secretary of said board and attested by the seal thereof. The fee for such examination shall be $10, and shall be paid by the applicant to the treasurer of said board toward defraying the expenses thereof; and such board may revoke or refuse to license for unprofessional or dishonorable conduct, subject, however, to the right of such applicant to appeal from the decision of said board, refusing or revoking such license as hereinafter provided." The section also contains a reciprocity clause which is ineffective as no other state boards have made arrangements complying with the Washington law.

No provision is made by the state law authorizing the issuance of a temporary permit to practice pending the meeting of the board. The standard requirements for those having practiced ten years or over is a general average of 70 per cent. Those having practiced less than ten years are required to have obtained an average of 75 per cent. Section 4 gives the definition of an unprofessional or dishonorable conduct, in the same words as in the Oregon statute. Section 8 prescribes penalties for illegal practice and defines the same: "Any person shall be deemed as practicing within the meaning of this act who shall have and maintain an office or place of business with his or her name and the words 'physician' or 'surgeon,' 'doctor,' 'M.D.,' 'M.B.,' in public view, or shall assume or advertise the title of doctor or any title which shall show or shall tend to show that the person assuming or advertising the same is a lawful practitioner of any of the branches of medicine or surgery in such a manner as to convey the impression that he or she is a practitioner of medicine or surgery under the laws of this state, or any person who shall practice medicine under a false or assumed name, or under cover of the name of some legal practitioner, or personate any legal practitioner, or for a fee prescribe or direct, or recommend for the use of any person any drug or medicine for the treatment, care, relief of any wound, fracture or bodily injury, infirmity or disease. Provided, however, this act shall not apply to dentists while confining themselves strictly to dentistry. Justices of the peace and the superior court shall have

concurrent jurisdiction of violations of this act." It shall be the duty of the respective county or district attorneys to prosecute all violations of this act. The board meets alternately in Eastern and Western Washington at such places as it may designate, in the first Tuesday of January and July of each year. Special meetings may be held when necessary.

Secretary state medical examining board, Dr. J. P. Turney, Davenport.

WEST VIRGINIA.

The state board of health, consisting of two physicians, graduates of reputable medical colleges and of six years' continuous experience in medical practice in each congressional district are appointed by the governor, and have regulation of practice of medicine in the state.

"The state board of health shall at such times as a majority of them shall deem proper, hold examinations, for the licensing of practitioners of medicine. Such examinations shall not be less in number than three, during each year, and shall be held at such points in the state as shall be most convenient to those presenting themselves for examination, or to the state board of health. At such examinations written and oral questions shall be submitted to the applicants for license, covering all the essential branches of the sciences or medicine and surgery, and the examination shall be a thorough and decisive test of the knowledge and ability of the applicant. The president and secretary of the state board of health shall issue certificates to all who successfully pass the said examination, and such certificates, after having been duly recorded as hereinafter provided, shall be deemed licenses to practice medicine and surgery in all their branches of this state. The state board of health shall give timely notice of the time and place of holding each such examination, by publishing such notice in at least three newspapers of general circulation in this state, and all persons wishing to present themselves for examination should notify the secretary of the state board of health to that effect. No applicant for license to practice medicine in this state shall be rejected because of his or her adherence to any particular school or theory of medicine. The state board of health shall call to their assistance, in the examination of any applicant who professes the homeopathic or eclectic school of medicine, a homeopathic or eclectic physician duly licensed to practice medicine in the state, and such homeopathic or eclectic physician so called to the assistance of the state board of health, shall be allowed the per diem and actual expenses incurred, hereinafter allowed to regular members of the state board of health; provided, however, that the provisions of this and the preceding section shall not apply to the physicians living in other states and duly qualified to practice medicine therein, who shall be called into consultation in this state by a physician legally entitled to practice medicine in this state under these sections. Every person on presenting himself for examination as hereinbefore provided, shall pay to the state board of health, or to the members thereof by whom he is examined, a fee of $10, which shall not be returned if a certificate be refused him. But he may again at any time within one year after such refusal, present himself for examination as aforesaid, without the payment of an additional fee, and if a certificate be again refused him, he may as often as he sees fit thereafter, on the payment of a fee of $10, be examined as herein provided, until he obtains such certificate. Any person shall be regarded as practicing medicine, within the meaning of this chapter, who shall profess publicly to be a physician, and to prescribe for the sick or who shall append to his name the letters 'M.D.' This act shall also apply to apothecaries and pharmacists who prescribe for the sick. This act shall not apply to commissioned officers of the United States Army and Navy and Marine-Hospital Service."

Certificates may be revoked for malpractice or dishonorable conduct, with right of appeal to circuit court. Secretary state board of health, Dr. A. R. Barbee, Point Pleasant.

WISCONSIN.

The board of medical examiners is appointed by the governor from lists furnished by respective state medical societies of the regular, homeopathic, eclectic and osteopathic schools of practice. Three of the members shall be regular, two homeopaths, two eclectics, and one osteopath. The board holds regular meetings on the second Tuesdays in July, at the Park Hotel, in Madison; October, at the Athearn Hotel, in Oshkosh; January and April, at the Hotel Pfister, in Milwaukee, and may hold such other meetings at such other times and places as may be deemed necessary.

All persons commencing the practice of medicine or surgery in any of their branches, shall apply to said board at the time and place designated by the board or at any regular meeting for license so to do, and shall submit to an examination in the various branches of medicine and surgery and present to said board a diploma from a reputable medical college that requires at least four courses of not less than six months each before graduation; no two of said courses to be taken within any one twelve months, and that shall after the year 1901 require for admission thereto an elementary education equivalent to that necessary for entry to the junior class of an accredited high school of this state, including one year's course in Latin, and for graduation from said medical college at least four courses of not less than seven months each; no two of said courses to be taken within any one twelve months, provided, however, that any student who is now matriculated in any medical college of this state which requires four courses of six months each as a prerequisite of graduation, no two courses to be taken within one twelvemonth, shall, on presentation of his diploma from such medical college and on payment of the fees specified in this act, be admitted to practice without further examination by such state board of medical examiners. The examination in materia medica, therapeutics, and practice of medicine shall be conducted by members of said board representing the school of medicine which the applicant claims to follow. The fee for such examination shall be fixed by the board, but shall not exceed $10, and $5 additional for the certificate if issued; such fee shall be paid by the applicant to the treasurer of the board, to be applied toward defraying the expenses of the board. If any person licensed by said board shall be convicted of any crime committed in the course of his professional conduct, the court in which such conviction is had, may, in addition to any other punishment imposed pursuant to law, revoke such license. Said board shall have the power to adopt such rules for its government and may require the filling out of such blanks as it may deem necessary to get at the true character and qualifications of applicant for license, and may use discretionary power in refusing license to any who cannot furnish proof of good morals and professional character. The person so receiving such license shall record the same with the county clerk in the county of his residence. Any practitioner of medicine holding a certificate from any other state board imposing requirements equal to those established by the board provided for herein, may on presentation of the same with a diploma, be admitted to practice in this state without an examination, at the discretion of the board on the payment of the fee. United States Army, Navy and Marine-Hospital surgeons, consultants from without the state, and students practicing under direct supervision of a preceptor are exempted from the provisions of this law.

Section 1435. "Every person shall be regarded as practicing medicine within the meaning of this section, who shall append the letters M.D. or M.B. to his or her name, with intent to represent that he or she is a physician or surgeon, or who shall for a fee prescribe drugs or other medical or surgical treatment for the cure or relief of any wound, fracture, bodily injury, infirmity or disease. Said sections shall not apply to dentists in the practice of their profession. It shall be the duty of the board of medical examiners to investigate all complaints of disregard, non-compliance or violation of the aforesaid sections, and bring all such cases to the notice of the proper prosecuting officer; and it shall be the duty of the respective district attorneys to prosecute violations thereof.

Section 1436. No person practicing physic or surgery, or both, shall have the right to collect in any action in any court fees or compensation for the performance of any medical or surgical service or to testify in a professional capacity as a physician or surgeon in any case unless he, before April 20, 1897, received a diploma from some incorporated medical college or society, or shall since said date have received a license from the state board of medical examiners; provided, that in all criminal actions the court may in its discretion and in furtherance of justice, receive the testimony of any physican or surgeon without requiring proof of the incorporation of the medical society or college from which he graduated."

Section 4603a. Any person prohibited by Section 1436 from testifying in a professional capacity as a physician or surgeon who shall assume the title of doctor of medicine, physician or surgeon by means of any abbreviation or by the use of any word, words, letter or letters of the English or any other alphabet, or by any device whatsoever, printed, written, painted or exhibited in any advertisement, circular, handbill, letter or other instrument, or on any card, sign, door or place shall be punished by fine of not less than $25, nor more than $100, or by imprisonment in the county jail not less than ten days nor more than sixty days for each offense. In any prosecution hereunder the burden of establishing the defendant's right to use any such title shall be upon him; provided, that women may practice midwifery, and that veterinary surgeons may practice in their special departments without being subject to the provisions of this section.

Secretary board of medical examiners, Dr. H. M. Ludwig, Richland Center.

WYOMING.

The state board of medical examiners is appointed by the governor. "Every person desiring to practice medicine or surgery, or who may publicly profess to cure or treat disease, injury or deformity in any manner whatever in this state, must be examined by the state board of medical examiners and pay a fee of $25 for such examination provided; that any person who shall present to said board a diploma from some medical college of recognized merit, said college being a member of the American Association of Medical Colleges, the Homeopathic Institute, or the National Eclectic Medical Association, or any college of similar standing in foreign countries, may receive a certificate from said board without examination, for which a fee of $5 shall be paid by each graduate. The certificate issued by the board must be filed for record in the office of the county clerk of the county in which such person desires to practice."

The examinations shall be of an elementary and practical character, and shall be upon the following subjects: Anatomy, physiology, chemistry, pathology, materia medica and therapeutics, hygiene, theory and practice of medicine, surgery and obstetrics, and sufficiently strict to test the qualifications of the candidate as a practitioner. Students may prescribe, under immediate supervision of preceptors, and gratuitous service may be offered in case of emergency. Lawfully qualified physicians, residing in other states or countries, may hold consultations with physicians in this state, and any physician or surgeon residing upon the border of a neighboring state, in which he is authorized to practice, whose practice extends into this state, may practice without filing a diploma with the board, as before provided. This act does not apply to commissioned surgeons of the United States Army and Navy or medical examiners of relief departments of railroad companies.

The state board of medical examiners shall examine all persons upon the theory and practice of obstetrics who openly profess to practice obstetrics or midwifery, who do not have authority to practice medicine or surgery; and they may issue to such candidates and person or persons who shall pass a satisfactory examination, certificates which shall authorize and empower them to practice obstetrics or midwifery. No person shall practice obstetrics or midwifery unless either a practicing physician authorized to practice under the provision of this act, or holding such certificates as are prescribed by this section; provided, that nothing in this section shall be construed to prohibit persons from rendering services in case of obstetrics or midwifery in cases of emergency.

Unqualified itinerant physicians and nostrum venders are prohibited under penalty. Board meets at Laramie, about March 15, 1902. Examinations may be held at any time, by giving ten days' notice to secretary of state board of medical examiners, Dr. G. P. Johnston, Cheyenne.

On the following page we give a tabulated statement of some of the principal features of the different state laws, including the conditions as to examination, admission to practice by diploma, etc., and the composition of the licensing boards.

[1]Diploma is not required for admission to examination by state board, but is necessary in examination by county boards.

[2]County boards are provided for by the Arkansas law, but registration of diploma is said to be only required.

[3]District boards appointed.

[4]Graduates of Illinois medical colleges may be exempted from examination, but this provision of the law is not regarded as mandatory by the board.

[5]The board has the power, at its discretion, to grant license without examination to graduates of legally chartered medical colleges of the United States or foreign countries. The Kansas law, as will be seen in the text, does not specifically require a diploma as a prerequisite for examination for license, but specifies that satisfactory evidence be furnished of three (and after January, 1902, four) years' study of medicine.

[6]Only a minority of the medical colleges are recognized by the board: a list is furnished on application. Graduates of all others must pass an examination.

[7]New Jersey has a special provision for permitting physicians not otherwise qualified by law to temporarily take charge of a qualified physician's practice at his request for a period of not less than two weeks or exceeding four months. Application must be made for this special license, and a fee of $2 paid.

In a number of the states the different schools of practice are not recognized in the law, hence it is not always possible to say whether they have representatives on the examining board or not.

[8]Vermont has also homeopathic and eclectic societies which make their own rules and prescribe conditions for license.

THE PROVINCES AND TERRITORIES OF THE DOMINION OF CANADA.

The Dominion consists of seven provinces, and the Northwest Territories. Of these, Ontario requires from a student five years of medical study, and Quebec is expected to demand soon the same length of time. The other provinces require a study of four years. The five older, namely Ontario, Nova Scotia, Quebec, New Brunswick, and Prince Edward Island, exercise a supervision over the matriculation and course of study. Moreover, Ontario, Nova Scotia, New Brunswick, Prince Edward Island and British Columbia require a final professional examination; Ontario calls also for an intermediate examination, at end of second year of study. There is no reciprocity at present existing between the provinces, but the new, sparsely populated provinces and territories admit licentiates from the others. Dr. Thomas G. Roddick's inter-provincial Registration Bill is now before the Dominion House; it creates a "Medical Council of Canada." The medical requirements of Newfoundland are similar to those of Manitoba.

ONTARIO.

"The College of Physicians and Surgeons of Ontario" is the name adopted by the medical profession in Ontario in its corporate capacity. The "Council" of the College of Physicians and Surgeons of Ontario is empowered and directed to enact by-laws for the regulation of all matters connected with medical education; for the admission and enrolment of students of medicine; for determining from time to time the curriculum of the studies to be pursued by them, and to appoint a board of examiners, before whom all must pass a satisfactory examination before they can be legally qualified to practice in Ontario. The Council consists of 17 territorial and 8 collegiate representatives, and 5 homeopaths.

Matriculation.—Every medical student must be registered in the manner prescribed by the Council, and this shall be held as preliminary to his medical studies, which shall not be considered to begin until after the date of such registration. The matriculating student must satisfy the Council that he is a graduate in arts, or has passed the senior matriculation or examination at end of the firsts year in arts, at any university in the British dominions; or present a certificate that he has passed the examination conducted by the education department on the course prescribed for matriculation in arts, including chemistry and physics, and approved by the lieutenant-governor.

Curriculum.—Every student must spend a period of five years in actual professional studies, except graduates in art or science of any college or university recognized by the Council, who have spent two years in the course of physics, chemistry, biology and physiology, and have passed examinations in their university course on the said subjects while taking their degree; such students will be required to spend four years in the study of medicine.

Examinations.—The professional examinations are divided into three parts: Primary, intermediate and final. The primary shall be undergone after the second winter session; the intermediate after the fourth winter ession; the final after the fifth year. Fees, registration of matriculation, $20; primary examination, $30; intermediate and final examination, $50; registration of membership (license), $25; registration of additional degrees, $2; annual assessment, $2.

NOVA SCOTIA.

The Provincial Medical Board consists of 13 practitioners of at least seven years' standing, 7 of which are appointed by the governor, and 6 elected by the Medical Society (i. e., the profession). To obtain a license each applicant must pursue the following course:

Matriculation.—No person shall begin the study of medicine, in order to qualify himself for practice in this province, unless he has first completed his 16th year, paid a fee of $10, presented satisfactory college certificate, or passed the examination prescribed by the board.

Curriculum.—Every student must attend, in the study of medicine, four collegiate sessions, of at least eight months each year.

Professional Examinations consist of the following: First professional, after end of second year of medical study, fee, $15; second professional, at end of third year of study, fee, $10; third professional, at end of fourth year, fee, $25.

QUEBEC.

The Quebec Medical Act of 1896 enacts as follows: 1. Every medical student must pursue his professional studies during a period of not less than four years without interruption from the time of his having passed the preliminary examination. 2. Of the above four years, four six-month sessions at least must be passed in attendance on lectures at a university, college or incorporated school of medicine recognized by the board. A certificate of study from a licensed physician for the period intervening between the courses which the student has attended will also be required. This certificate shall not be called for, if the candidate has followed four nine-month courses.

In order to register a diploma in medicine in the Province of Quebec and to obtain a license it is necessary that all students must pass a preliminary examination before the examiners appointed by the Council, or produce a certificate of having passed an equivalent preliminary examination before a college or licensing board recognized by the Council of the College of Physicians and Surgeons of Quebec."

NEW BRUNSWICK.

The Medical Council of Physicians and Surgeons of New Brunswick is composed of nine legally qualified medical practitioners of not less than seven years' standing, four of whom are appointed by the governor and five by the New Brunswick Medical Society (of which every licensed practitioner is a member).

Matriculation.—Hereinafter (1881) no person shall begin or enter upon the study of physics, surgery or midwifery, for the purpose of qualifying himself to practice the same unless he shall have obtained from the Council a certificate that he has satisfactorily passed a matriculation or preliminary examination or unless he has passed a matriculation examination in arts and science at some recognized college.

Registration.—In order to obtain a license to practice the applicant must have passed the preliminary examination; he must have studied medicine during four years; he must have passed the professional examination irrespective of any diploma which he may possess. The professional examination is held in St. John annually in June.

PRINCE EDWARD ISLAND.

The Council of the Medical Society (i. e., medical profession)

of Prince Edward Island is composed of seven members elected by the registered members of the Society. Every applicant for registration must satisfy the Council: 1. That he has passed a preliminary or matriculation examination on the subjects specified in the by-laws of the Council, and had his name registered in the Medical Students' Register; any person holding the degree of B.A. from a university in the British dominions, or a teacher's first-class certificate of this province, is exempted; 2, that after such examination and registration, he has studied medicine four years in a university or medical college of good standing; 3, that he has satisfactorily passed a professional examination before the council.

BRITISH COLUMBIA.

The College of Physicians and Surgeons of British Columbia is the corporate name of the medical profession of the province. Its Council is composed of six members, elected for three years. The Council admits upon the register any person who shall produce a diploma from any medical college requiring at least four years' course of study, provided that where the college did not require a course of study of at least four years, a post-graduate course added in point of time to that of the college, completes the four-year course; provided, also, that the applicant shall furnish satisfactory evidence of identification, and pass before the members thereof a satisfactory examination in anatomy, chemistry, materia medica, medical jurisprudence, midwifery and diseases of women and children, pathology, physiology, surgery, and theory and practice of medicine.

MANITOBA.

The Council of the College of Physicians and Surgeons of Manitoba consists of 11 territorial, 3 collegiate and 1 homeopathic representatives. The following are entitled to registration as practitioners: 1, members of any incorporated college of physicians and surgeons of any province of the Dominion; 2, those qualified to practice in Great Britain and Ireland; 3, graduates in medicine of the University of Manitoba; 4, others must give evidence of qualification by examination, if necessary, to the Council of the University of Manitoba, which is the sole examining body in medicine in the province.

NORTHWEST TERRITORIES.

The Council of the College of Physicians and Surgeons of the Northwest Territories consists of five elective members. The Council shall admit upon the register, 1, any person possessing a diploma from any medical school in Great Britain and Ireland having power to grant such diploma, and who shall produce such diploma and furnish satisfactory evidence of identification; 2, any member of an incorporated college of physicians and surgeons of any province of the Dominion of Canada; 3, any person producing a diploma from any recognized medical college requiring a four-year course; provided that the applicant shall pass a satisfactory examination before the Council. Fees for examination, $50; registration, $50; annual assessment, $2; permits to practice are not granted by the Council.

Clinical Report.

A CASE OF SENILE GANGRENE.*

JAMES A. ROLLS, M.D.
WATROUS, NEW MEXICO.

S. G., Mexican, aged 78, has always been a man of temperate habits, no history of venereal disease, enjoyed good health and was exceptionally robust until 56 years of age, at which time his right foot became gangrenous without any apparent cause. Dr. W. R. Tipton of Las Vegas, to whom the case was referred at that time, August, 1877, has kindly given me the following notes from his records: "The disease began with pain in the sole of the foot, the toes became cold and assumed a purplish color; finally they became somewhat edematous and a spreading gangrene developed; amputated through the calf of the leg, and the gangrene appearing in both flaps, did a subsequent operation at the upper third of the thigh, which was entirely successful."

After this operation the patient's health remained good for twenty-three years. On February 1, however, he noticed some numbness in the left foot and began to suffer considerable pain, referred to the ankle joint, particularly at night. I saw him for the first time February 14. Examination at this time revealed the following condition: Patient is a large, powerfully-built man of good muscular development, well nourished; temperature normal; pulse 80, of high tension; radial and temporal arteries firmer than normal but by no means rigid; no heart lesions; urine normal; appetite and digestion fair; bowels act normally. A small, almost circular, patch of dry dark wrinkled skin about the size of a quarter and adherent to the deeper tissues is situated over the navicular and internal cuneiform bones of the left foot. The foot was markedly cold to the touch, and movement caused pain at the ankle joint and in the leg above the ankle.

Since there were at that time no constitutional symptoms, I directed that the foot be kept elevated and wrapped in batting; that the patient be given a more than usually generous diet and prescribed full doses of opium to be given at night, because from pain the patient lost a good deal of sleep.

On March 22 nearly the whole of the foot, from the ankle joint down, except the posterior aspect of the heel, was in a dry, black, withered condition, painless to the touch, and, in fact, quite dead. The appearance of the foot, indeed, tallied exactly with the classic descriptions of dry gangrene, resembling as it did, nothing more than the varnished foot of a mummy. It was noteworthy, however, that in the sole of the foot, two small blebs had formed, and crepitation could be elicited on palpation, showing that the post-tibial artery had kept up a better blood supply than the anterior. The temperature was at this time a little over 100, and the pulse 110.

On April 9 the gangrenous condition had reached the junction of the lower and middle third of the leg anteriorly, while on the posterior aspect there seemed to be a greater amount of resistance to the process; moist sloughs had formed and the odor was very foul. Systemic poisoning was now quite marked, the pulse being small, at 120, temperature 102.

As there seemed no indication that a line of demarcation would form, I performed an amputation through the condyles of the femur on April 14, just ten weeks after the onset of the disease, and as there was little or no chance that the patient would want to use the stump, I made the flaps more nearly equal in length than in Carden's operation in order to avoid the danger of gangrene in a long, thin, anterior flap. In choosing the knee as the site of operation, I had the advantage of the experience of Dr. Tipton with the right leg, and was also influenced by the fact that there was reason to believe that the anterior tibial was the chief artery affected, and, since the obstruction is usually greatest just where the branch leaves the main artery, that as a consequence any tissue depending upon it for nourishment would undoubtedly perish. In this connection Dr. Steven Smith reports the case in the *Philadelphia Med. Journal*, Oct. 29, 1898, of a man aged 78, suffering from senile gangrene in whom he chose the knee joint as the seat of amputation without waiting for a line of demarcation. He points out that at the knee there are eight arterial branches and shapes his flaps so as to injure them as little as possible..

In the present case the wound did well and was nearly healed, when, 20 days after the operation an incident occurred which showed this old man's enormous vitality. He developed a double broncho-pneumonia and for two days lay in a semi-comatose condition, but finally rallied and is to-day in good health and earning a living by teaching in a Mexican school.

The point I found most difficult to determine was: In such a case when and where should operation be done? In the scanty literature to which I have had access one thing seems clear, namely, that authorities even in the present decade have divided themselves into two groups in discussing this subject. On the one hand are those who censure any operation done below the tubercle of the tibia and advocate operation at a very early date. On the other are those who say that it is very seldom necessary to go as high as the knee and advocate waiting at all hazards for a line of demarcation. Hutchinson in England, and Heidenhain in Germany, have of late been the advocates of early and high operations, while Landow takes the opposite view and advocates waiting for a line of demarcation in the foot and operating just above it, and if the process shows no sign of being limited to the foot he operates through the calf of the leg. The latter procedure would certainly have failed in the present case, as Dr. Tipton found the lower part of the superficial femoral entirely occluded, while in the left leg, although the anterior tibial was pervious, the walls were so thickened, especially at the upper part, that the lumen was very much encroached upon. This, to some extent, bears out Heidenhain's figures that the vessels affected in order of frequency are the anterior tibial, the superficial femoral, and the profunda femoris, this last being very rarely the diseased vessel.

RECIPROCITY OR UNIFORM MEDICAL LEGISLATION.

The desirability of a uniform standard of qualifications for practice throughout the United States is self-evident and is recognized in the reciprocity clauses contained in the medical practice acts of many of the states. That these reciprocity clauses are for the most part ineffective is due to many reasons, some of them valid, others perhaps not so unqualifiedly so. Each state makes its own medical law and establishes its standards. Any legal differences in these or any assumed laxity in the execution of the law may be made the cause of refusal of reciprocity, even when this is provided for in the statute. So long as there is no co-operation between the makers of the laws there can be no reciprocity.

Each state law is more or less modified to meet the imagined special local needs or interests and without regard to those of other states where different conditions may be imagined to exist. Further, while there has been an obvious intent to adopt the good features of similar laws of other states, sufficient care has often not been used to avoid their mistakes, and to note the legal questions that have arisen and that may apply to the proposed legislation. The give-and-take element, the element of compromise, which is almost inevitable in the construction of such laws, is entirely ignored as far as possible relations with other states in the union are concerned. The fact that these compromises are made in favor of internal interests is itself a potent reason for the rejection of reciprocity by other commonwealths. If we add to these reasons the fact that there is a not unpraiseworthy desire of each state in constructing its own practice act to improve on the laws of other states, and that variations made with this in view are naturally the most serious obstacles to reciprocity, we have no difficulty in appreciating the reasons why it has not been effected. The result of this state of affairs is a disastrous one in many ways; it is not only inconvenient to the individual practitioner, but it also tends to lower the standing of American physicians throughout the world. We are not judged elsewhere by our highest standards as much as by our lowest; in our medical as well as in other relations we are looked upon by foreigners as a Nation with a large N, and the minor state distinctions do not count. There need be no question as to the wisdom and policy of establishing a uniform high standard universally recognized within our national territories if it can in any way be shown possible.

The most obvious remedy for this unfortunate state of affairs, were it practicable, would be a national standard of medical qualifications, but this is impossible under our federal constitution. We have here the same governmental weakness that is felt when we come to deal with other health matters such as quarantine between the states, and in our marriage and divorce legislation.

A valuable, and it may be some time a fruitful, suggestion has been offered by Dr. C. K. Fleming in a recent address.[1] He points out that the National Government has the power and right to assist any state in any internal matter in which it may request or desire such aid, and suggests that the medical profession unite in the demand for a national bureau of health and medicine. Together with the investigation of health matters generally, one of the duties of this bureau is thus proposed: "This bureau should investigate the condition of the medical profession in the various states of the union, should classify the profession so far as possible with reference to determining the relative proficiency and efficiency of physicians in various states; should likewise investigate the laws regarding the licensing of physicians and the laws providing for the revocation of licenses, the grounds therefor, and the proceedings necessary to be taken in order to revoke licenses, the intellectual and moral standards required in the various states of the physicians, and generally to make a report in the regular annual report of the bureau, and full and complete investigation of the medical laws in the various states, with such recommendations as the bureau shall deem wise, such suggestions to be placed in the form of proposed legislative enactments, to be passed in full by such states as may agree to adopt the suggestions. As soon as practicable and as soon as such investigation can be made as will warrant that step, the bureau should prescribe a full and complete set of laws, rules and regulations for the admission of physicians to the practice of medicine, for the controlling of physicians in the practice of medicine, and for the entire government of the profession in the various states; such legislation to be adopted by such states as may care to adopt it. Of course, the proposed legislation should embody such standards and such regulations as shall tend to uplift the profession and place it upon the high plane to which it aspires, and the regulations should be such as not to be irksome, but sufficient to prevent abuse and so planned as to give the greatest freedom of movement of physicians from one part of the country to another and to insure the greatest possible encouragement to those proposing to enter the profession upon legitimate lines." In addition to the above he also suggests that the bureau should investigate and classify in its reports the various medical colleges with reference to their comparative efficiency and otherwise indicate the means to bring medical education to the highest practical plane of excellence. Of course, the law organizing the board should be so drawn up as to prevent its becoming a

1. Denver Medical Times, October, 1901.

creature of the politicians; and there is sufficient precedent in the present scientific bureaus at Washington to insure this being possible.

This, however, is not the only way in which the medical profession of the country can work, we believe efficiently, for the desired results. Every law regulating medical practice has heretofore been the product of the local organized profession; a national practice act will have to be the result of the co-operative endeavor and influence of the profession throughout the whole country. It may be that this can be best directed to the establishment of such a government bureau as above directed, but this is not all that can be done. The national organization of the profession, the AMERICAN MEDICAL ASSOCIATION, can and should take up this problem through the recently constituted House of Delegates. Committees should be formed to study the subject, to take and analyze the merits and defects of the state laws, to take note of the legal questions that have been developed and their solution, and to draw up tentatively the ideal standard which can be submitted to and discussed by the other organizations interested. The counsel of the leading representatives of the profession could not be better given in any other way.

The establishing of a high national standard of medical qualifications for government purposes as a requisite for government appointments not subject to examination, etc., while not binding on the states, could hardly fail to have a good effect on the professional standing at home and abroad. It would give foreigners a basis on which to judge us and should raise the general estimate of the American medical profession. The state qualifications are at present ignored by them, but they could hardly overlook a national license. And at home, if the plans here suggested are followed, it is reasonable to think it could hardly fail to have a general elevating tendency and in a short time lead to a uniform qualification throughout the states and thus be solved the question of reciprocity.

ENFORCEMENT OF MEDICAL LAWS.

To get results in the regulation of the practice of medicine, it is necessary first to get the needed legislation, and then to enforce the laws. To simply put the laws on the statute books and do nothing to enforce them is only half accomplishing the good sought to be obtained. Axiomatic as this may be, the idea has never seemed to be appreciated in the past by those who have been working for legislative enactments and for the regulation of the practice of medicine. Time, energy and money have been spent to get the necessary laws by committees of our state societies and by others, but this accomplished, nothing more has been done. Laws will not enforce themselves.

If a law is one whose enforcement will give satisfaction to all—except the one who has infringed it and who will suffer by its enforcement—there is no hesitancy on the part of the police, public prosecutor or the judiciary in punishing law-breakers. When the law affects only a certain class, it is different, even if the ultimate object of that law is for the good of the public. For instance there are laws made, in the interest of the health of the community, to secure sanitary plumbing, the direct effect of which is on the plumbers, compelling these to be qualified to do the work, and licensing them for this purpose. The plumbers' association sees that these laws are enforced, at least so far as it applies to their craft. Similar illustrations might be quoted. Nearly all states have laws for the protection of dumb animals, yet these are seldom enforced, except where associations, such as the humane societies, have been created to enforce them.

There are now laws on the statute books of practically every state and territory whose objects indirectly are for the protection of the people against quacks, charlatans and medical pretenders. Directly, however, these laws affect the medical profession. Their enforcement is expected to benefit the profession by limiting membership in it to those who are, nominally at least, honorable and qualified for the duties its members assume.

That the medical profession is directly interested is shown by the fact that all of these laws have been enacted on the demand and through the efforts of medical men. As the public is not closely interested, those who are elected by the public to see that the laws are enforced, and who cater to public sentiment, are liable to neglect their duties as regards enforcing these special laws, because "there is nothing in it" for them. Theoretically, the prosecuting attorneys are expected to enforce all laws, including those regulating the practice of medicine. Practically, they have not done so and will not do so. This is a condition that we might as well recognize and act accordingly, if we expect to have these laws enforced.

Dr. Harison[1] calls especial attention to this difficulty, and his remedy is "for medical men to devote their energy toward compelling the prosecuting or district attorneys to do their duty under the law." From the theoretical point of view, this advice may be correct, but practically, such energy would be wasted. Under present conditions these public prosecutors have nothing to gain by prosecuting illegal practitioners—neither political favor nor the applause of the populace.

Dr. Happel[2] gives the true remedy for the laxness in the enforcement of these laws. The remedy for this is, as for most of the curses which affect our profession, organization. As he says, well-organized, wide-awake county societies are the effective weapons for enforcing the laws, either from the fact that their political influence is sufficient to force the public prosecutor to do his duty, or because they are wide awake enough to employ an attorney to do it without the aid of a public prosecutor. There are scores of such county societies scattered through the country that will verify the assertion of Dr. Happel, but the difficulty here lies

1. See page 1303.
2. See page 1301.

in the fact that the profession in adjoining counties is unorganized and does nothing. This compels the active society to be on the alert all the time to keep out of their borders those who are permitted to practice in the adjoining territory.

What is needed is a well-organized active state society with its branches ramifying into every county and with a paid attorney of its own to act for the profession, independent of, or as an assistant to, the public prosecutor. We say "paid attorney," because from our experience and observation, we are confident that in no other way will the medical laws be enforced. Of course, to employ an attorney takes money, and to get money the state society must be supported by the whole profession of the state in a financial way. Not only is it necessary to have the financial support of the profession of the state, but also an organization in each county to report infringements of the law and to aid and coöperate with the state society. Then the whole territory would be covered and, with the mutual help, no difficulty would arise. This needs a more systematic organization than now exists in most of the states.

Reference has often been made to the effective work that has been done in Kentucky in ridding that state of quacks. The workers there get discouraged sometimes because of the fact that the profession in adjoining states is doing nothing, which makes it so much the harder for them. If like work were done in other states as is being done in Kentucky, there would soon be an end of quacks, pretenders and charlatans in the whole of the United States. The enforcement of the medical laws needs not only the coöperation of the county and state societies, but, as well, coöperative work among the various states.

TYPHOID PNEUMONIA.

Distinction is to be made between pneumonia with so-called typhoid symptoms, pneumonia due to mixed infection in the course of typhoid fever, and pneumonia due wholly or in part to the bacillus of typhoid fever. Strictly speaking, the term typhoid pneumonia perhaps should be limited to the last condition of which there are a few interesting instances on record, instances that bear scrutiny from the bacteriologic point of view. Typhoid bacilli have been isolated from pulmonary consolidations in typhoid fever a number of times after death, but writers, such as A. Fraenkel, are of the opinion that in most of these cases to the bacillus should be assigned only secondary importance in the etiology of the complicating pneumonia. In two cases of lobar pneumonia in typhoid fever, V. Stühlern[1] isolated during life the typhoid bacillus from the sputum, which in both instances was markedly hemorrhagic. In one of the cases he found the bacillus also in the material withdrawn by means of a syringe from the consolidated lung—lower and middle right lobes. In addition, he found also the micrococcus lanceolatus. In these two cases the typhoid bacillus was present, then, in the alveolar exudate, whence it was discharged with the sputum. In a third case of pneumonia in typhoid fever examined postmortem there were present in the lung diplococci and typhoid bacilli, and the pneumonia had a pronounced hemorrhagic character. Curschmann emphasizes the fact that pneumonias in typhoid fever more frequently give a hemorrhagic sputum than the common, genuine lobar pneumonias. Recently Dieudonne[2] reports another instance of pneumonia in typhoid fever with hemorrhagic sputum, diplococci and typhoid bacilli in the latter. Later, the sputum contained typhoid bacilli in pure culture. In this case the clinical picture presented was essentially that of pneumonia, and typhoid bacilli were present in the sputum for seven weeks and after convalescence was well established.

Cases like those mentioned in the foregoing show that the sputum in typhoid infection may be an important factor in spreading the bacillus of typhoid fever, just as in pest pneumonia the sputum is also a dangerous carrier of the pest bacilli. The importance of careful disinfection of sputum under these circumstances is self-evident. Hemorrhagic expectorate in the pneumonias complicating typhoid and also in apparent primary pneumonia should awaken the suspicion of the physician if the possibility that typhoid bacilli may be present and thus lead to further bacteriologic examinations of this class of cases which is highly desirable for a thorough understanding of their real nature.

THE WRONG AND RIGHT WAY OF PROSECUTING ILLEGAL PRACTITIONERS.

In a certain town in a Western state a "cancer doctor," with no medical qualification, was pretending to cure not only cancers but other diseases also. On the instigation of some physicians he was arrested, taken before the justice court and fined. His lawyer appealed to the district court, and there the decision of the lower court was affirmed, but the attorney carried it to the supreme court. Meanwhile, the illegal practitioner kept on his work unmolested. In course of time the case came up before the supreme court, but those interested neglected to employ an attorney to follow it up, with the natural result that the case was thrown out and the cancer quack is still practicing in the same town; the physicians, disgusted at the outcome, are doing nothing there to suppress him. A few months afterward, in the same town, a Chinaman started with effective advertising and patients rushed to him. A few of the physicians employed a young attorney, who promised to carry the case through and rid the town of the Chinaman. He secured the names of some of the patients and had the Chinaman arrested, using one patient as witness. The Chinaman was fined, but appealed to the district court, giving bonds. The following day he was arrested and again fined. The day after, he was arrested twice, each time new witnesses in the form of patients being urged to appear against him and additional fines were assessed and bonds re-

2. Centralbl. f. Bakt., 1901, xxx, 481-483.

quired. Then, the Chinaman's attorney went to the physicians' attorney with a demand to know what he proposed to do, as the bonds given in each case were now amounting to quite a sum. The Chinaman's attorney was informed that his client would be prosecuted so long as he practiced illegally and that the cases would be followed to the supreme court if necessary. With that the Chinaman suddenly left the town and has never been heard of since. We give these as examples of two ways of enforcing the medical laws.

ANOTHER VICTIM TO OSTEOPATHY.

Osteopathy recently figured in a Toronto inquest, a woman having died suddenly at the office of one of these irregulars. She was being massaged for goiter, as it appears, and the manipulation of her tumor was followed by a hemorrhage into the lung with resulting suffocation and death. The osteopath, according to the reports, declared himself to be a product of the Kirksville school and claimed that it was not necessary for him to know anything about medicine. His case-book was brought into court and in it appeared cases diagnosed as typhoid, diphtheria and numerous other ailments. The jury verdict was a rather peculiar one: It acquitted every one from responsibility for the death, but condemned the treatment as dangerous, and expressed an opinion that strict laws should be enacted "to put an end to this dangerous practice and others of a kindred nature." Of course, until such law is made, the osteopath will probably go on; yet it is some satisfaction to know that the practice is condemned, even with a whitewash for the practitioner.

DEFINITION OF PRACTICE OF MEDICINE.

The proper wording of the definition of the practice of medicine is a point upon which, judging from the variance in state laws in this respect, there seems to be some difference of opinion. In several of the states no attempt is made to define it, the lawmakers evidently thinking it enough to leave it to the common acceptation of the meaning of the words. In other states they seem to have less faith in their judges and have more or less elaborately enumerated the acts that are included under this head. In some cases only a general definition is offered, such as "professing to practice or prescribing," "treating or professing to treat," etc. Others are more specific and give details, such as "using the designation of Dr. or M.D.," "diagnosing, suggesting or recommending remedies," etc. The element of compensation enters into many of the definitions, the practice is defined as doing all these for a fee. In some states the need is evidently felt of some specific statutory expression of what the practice of medicine is under the law, in others this is apparently not held to be so essential. While the public has only vague ideas on the subject in some respects, there would seem to be a sufficiently well understood established usage of the term that ought to be sufficient also in law. Admitting, however, the advisability of an explicit statutory definition, the important point is to have it the right one. A partial definition is worse than none, as its specifications are its limitations; what is not included, is not provided for. A too elaborate and detailed one gives the greater opportunity to pick flaws in its provisions and may by its excessive prohibitions excite opposition as attacking personal rights; a too loose and comprehensive one may possibly tempt a loose interpretation and nullify itself to a certain extent. The golden mean must be preserved, and this would seem at first sight to be not an easy task. With the variation of the theme however on our different state statute books, and the body of judge-made law that is accumulating there is a chance at least to learn something of what will and will not stand the legal tests and yet guard the public and the medical profession from the evils of illegal practice. A careful searching of supreme court reports would be a valuable aid in making up the definition of the practice of medicine. Those that have stood the test of attacks from varied points of view ought to be studied and from them a composite or adapted definition be compiled. It may be found that the simpler and briefer ones are the best.

CARE IN THE MANUFACTURE OF ANTITOXIN.

Serious results from the use of the diphtheric antitoxin in St. Louis are liable to do much harm through the use that will be made of them by those who are watching for a chance to fight the medical profession and by those who oppose serum therapy in general. That this is one of the avoidable accidents, it seems to us, can not be denied, although it is one of those peculiar cases in which it is hard to place the blame. Neither is the manufacture of antitoxin by the state or the municipality to be condemned on account of these results in St. Louis. While there is no blame to be attached to any one in particular, is it not possible that there has been a false economy on the part of authorities in utilizing broken-down horses of the police and fire departments and having them under charge of irresponsible poorhouse inmates while they were being used for serum inoculations? In the manufacture of such an important product as antitoxin there is need of the greatest care, of continued watchfulness, an absolute assurance of non-infection and non-infectious surroundings, and that only those who can be absolutely trusted in every respect should be employed, this including stable attendants. We do not charge the St. Louis Health Department with not having employed due precaution, but mention the possibility as it is suggested by reading the statements in the local press and those which appeared in our pages last week.[1] The question of economy should not be considered for a moment, as seems to be the case judging from the reports contained in the St. Louis papers. Commissioner Starkloff is quoted as saying that the city has been manufacturing its own antitoxin practically without cost, which is not an argument in favor of the continuation of such economy. The fact that it is cheaper supplied in this manner than to purchase it should not carry any weight whatever. The question to be considered is that of safety and guaranteed purity. It is strange, but a fact, that just now we are having more tetanus than usual in various parts of the country. In St. Louis it is said that other cases are occurring among children where antitoxin had not been used, and pos-

1. See pages 1258, 1260.

sibly a thorough investigation may result in unexpected developments and that perhaps more deaths have been credited to the use of the antitoxin than should have been.

Medical News.

ALABAMA.

Dr. William M. Mastin has reached Mobile after his trip round the world with Drs. Senn, Brower and Frank of Chicago.

The State's Health.—Dr. William H. Sanders, Mobile, state health officer, reports scarlet fever prevalent in several countries, but states that there have been no cases even suspicious of yellow fever this year.

CALIFORNIA.

Personal.—Dr. James W. Brown, Grass Valley, who was seriously injured in a runaway accident, October 17, is now convalescent.——Dr. Albert J. Underhill, a graduate of Johns Hopkins Medical School, Baltimore, has located in Los Angeles. ——Dr. William H. Flint, New York City, has returned to Santa Barbara, where he formerly resided, to spend the winter.

Elizabeth Bard Memorial Hospital, Ventura, will be opened to receive patients on December 1. The hospital has been established by Senator Thomas R. Bard and Dr. Cephas L. Bard in memory of their mother after whom the hospital is named. The building is to accommodate forty patients, will have connected with it a training school for nurses, and will cost about $30,000. Dr. Bard will have immediate supervision of the hospital.

Camp for Consumptives.—Hemet, Riverside County, has a health camp for the care of consumptives. It consists of twelve tents, one for each person, with a court for physical exercise and for sun baths. Each court is surrounded by a high duck wall to screen it from others. The treatment embraces living and sleeping in the open air and daily exposure of the naked body to sunshine and air, with proper food and exercise.

COLORADO.

Quarantine Against Plague.—Colorado still maintains a quarantine against Chinese from San Francisco.

Personal.—Dr. William T. H. Baker, Pueblo, has been made examiner of recruits at the Pueblo recruiting station, vice Dr. Warren, ordered to another post.——Dr. William C. Mitchell, Denver, bacteriologist of the State Board of Health, has returned from an official investigation of the plague situation in San Francisco.

Infectious Diseases.—The State Board of Health reports that during October 118 cases of diphtheria, 179 of scarlet fever and 54 of smallpox were reported. Compared with September, this shows an increase of 13 cases of diphtheria, 77 of scarlet fever and 39 of smallpox. The increase in smallpox is due to the failure at different places to recognize the first case.

New Sanitary Regulations.—The State Board of Health has adopted a sanitary code in which are two important regulations to go into effect Jan. 1, 1902. One requires the report of every case of typhoid fever by the attending physician or householder to the local health officer, and by him to the State Board of Health. The other requires the securing of a burial permit from the local health officer before any dead body can be buried or otherwise disposed of.

ILLINOIS.

Personal.—Dr. Amos J. Thornber, Powellton, has moved to Burlington, Iowa.——Dr. George Sibbard, Seneca, has opened an office in Morris.

Herman D. Cable Memorial.—The Herman D. Cable addition to the Evanston hospital, erected at a cost of $28,000, and accommodating 30 patients, was opened for public inspection, November 9.

Quarantine Regulations.—The Clinton Board of Health has formulated rules for quarantine and has directed that the health officer hereafter shall leave a copy of the regulations with each family quarantined.

Penalty for Unlicensed Practice.—Suit has been instituted against "Dr." Williams in the Union County Circuit court to compel him to pay $1100 in fines for practicing medicine in the state without a license. It is averred that Williams was warned more than a year ago by a member of the State Board of Health that he must cease practice until he should have complied with the requirements of the state law, but that he paid no attention to this warning and went on practicing.

Communicable Diseases,—Typhoid fever is epidemic in Kankakee, where 150 cases have occurred; the local health officer, Dr. William E. Scobey, is endeavoring to secure an investigation of local sanitary conditions and the adoption of measures for the present checking of the disease. Freeport has a number of cases.——Scarlet fever is said to be raging in Hamilton, where the schools have been closed. On account of the disease the schools of Ridott, Seward and Winnebago have been closed.——Diphtheria has appeared in Garrett Biblical Institute, Evanston, and in Ridott township.——Smallpox has caused the closure of four schools in the western part of Hancock County. Fourteen houses are quarantined in Red Bud. Gratton has fourteen cases of the disease. The Elvaston, Eagle and Brown schools have been closed on account of the prevalence of the disease.

Chicago.

Dr. F. Gregory Connell has been appointed surgeon to St. Vincent's Hospital, Leadville, Colo., and has left for his post of duty.

Registration of Nurses.—Graduate nurses of Chicago will ask from the next state legislature a law requiring the registration of trained nurses.

Bequest to Hospitals.—By the will of Mary Corrigan, Alexian Brothers' Hospital, St. Elizabeth's Hospital, St. Joseph's Hospital and St. Anthony's Hospital each receives $5000.

Beds Endowed.—Edward Finley and wife have donated property valued at $10,000 to found and maintain two free beds in the Hibbard ward at St. Luke's Hospital. They will be known as the "Edward Finley" and "Dorcas A. Finley" beds.

Illinois Medical College has purchased for $45,000 a piece of property 50 by 100 feet, at the southwest corner of Washington Boulevard and Halsted street, and after making extensive changes in the building, will use it as a medical college and dispensary.

Institute for Scientific Investigation of Infectious Diseases.—We understand that one of the wealthy families of Chicago is arranging to endow, in a most liberal manner, an institution for the study and scientific investigation of infectious diseases. The details and particulars have not yet been made public, but it is reported that it will be second in importance only to that of the gift by Mr. Rockefeller.

Exemption from Smallpox.—The continued exemption of the city from smallpox is a source of gratification to the Health Department. It is not too much to claim that Chicago's present freedom from the pest—no case since August 12—is due in great measure, at least, to the effects of the vaccination campaign. On the other hand, the fact developed that 15 per cent., or more than a quarter of a million of the population, is still unvaccinated.

Satisfactory Health Conditions.—Measured by the continued low death rate the public health conditions of Chicago seem to be eminently satisfactory. The number of deaths last week, 397, represents an annual rate of 11.77 per thousand of population. There were fewer deaths last week, as compared with the preceding week, from typhoid fever, Bright's disease, consumption and cancer. The mortality among infants and persons over 60 years of age was also lower, but among children between 1 and 5 years there was a slight increase. Diphtheria deaths during the week numbered 15, this being the highest number since the week ended Feb. 2, 1901, when 17 deaths were recorded from this disease. The diphtheria mortality for the year, however, is unusually light. Some spread of measles is noted.

INDIANA.

Diphtheria in mild form has invaded Greencastle and strict quarantine has been established.

A sanatorium is to be built at Hammond by Dr. James P. Henderson, to cost $20,000 and to accommodate 43 patients.

Physicians' Census.—The report for 1900 of the State Board of Medical Registration and Examination will show that there are in Indianapolis 647 physicians and about 6500 in the state.

Licenses Revoked.—The State Medical Board, on November 6, revoked the licenses of "Dr." Hibbard, who has a "gold cure"

at Marion, holding that he was not entitled to practice under the diploma he held, and that of "Dr." D. K. Boyer, Middlebury.

Personal.—Dr. F. E. Ray, formerly assistant physician at the Central Indiana Hospital for the Insane, has opened an office in Indianapolis.——Capt. Frank W. Foxworthy, assistant surgeon, U. S. Volunteers, who has been on duty in the Philippine Islands with the Thirty-fourth Infantry, and as superintendent of the City Hospital, Manila, has returned to Indianapolis and resumed practice.——Dr. George L. Perry, Westchester, has gone to Chicago to take a hospital position.

Deaths in October.—The Monthly Bulletin of the State Board of Health reports 2614 deaths in October, an annual rate of 12.2 per 1000. In the same month of 1900 there were 2933 deaths, a rate of 13.7 per 1000. The death-rates per 100,000 for 1900 and 1901, respectively, were, from tuberculosis, 134.5 and 135.5; diphtheria, 47.8 and 24.3; typhoid fever, 89.5 and 95.6; diarrheal diseases, 97 and 68.9; pneumonia, 63.7 and 60.4; cerebrospinal meningitis, 26.2 and 8.9; cancer, 37.9 and 43.1; violence, 50.6 and 49.7. The comparison is in favor of 1900, and being by rates is fair.

IOWA.

Isolation Hospital Burned.—Tracey Home, Des Moines, a hospital in which fifteen smallpox patients were quarantined, was badly damaged by fire, November 7. The inmates were rescued by firemen and police.

Quarantine Raised.—As no cases of contagion have arisen from the visit of a party of school teachers of Marshalltown to the Tama Indian Reservation, the local health authorities have ordered the quarantine raised.

Personal.—Dr. Robert A. Patchin, Des Moines, has been seriously ill, but is now improving.——Dr. Alexander M. Cowden, Grandview, has located at Washington.——Dr. John J. Ball, Creston, has moved to Brooklyn.

Smallpox Among Indians.—The member of the State Board of Health detailed to investigate the conditions in the Tama Indian Reservation regarding smallpox has reported that five deaths have occurred, that several cases exist and that the Indians refuse to be vaccinated.

KANSAS.

Measles is epidemic in Diamond Springs, Morris County.

Smallpox.—The situation in Fort Scott is alarming. There are now more than 20 cases in the city, and the Washington school has been closed. Baldwin has eight cases, all mild and all quarantined. One case is reported from Argentine.

Personal.—Dr. Robert N. Dinsmore, Richmond, has moved to Baldwin City, where he has bought the residence of Dr. Henry C. Owen.——Dr. John Maclay, Weir City, has purchased the residence of Dr. Dinsmore at Richmond, whom he will succeed in practice.

Hospitals Demanded.—The people of Kansas City are demanding that the city build a city hospital and an emergency hospital, as those at present existing are overtaxed, and are, in addition, private institutions dependent for their support on voluntary contributions.

Mitchell Hospital Opened.—The hospital annex of the Kansas State Protective Home, Leavenworth, was opened October 27. The building is for the use of colored people, contains 7 rooms and can accommodate 25 patients. Dr. Charles M. Moates is physician in charge and is assisted by Dr. Clarence C. Goddard and others.

MARYLAND.

Diphtheria is reported to be epidemic at Eastern Berlin and Westernport, where the public schools have been closed, and at Piedmont.

Typhoid with Relapses.—At his clinic November 9 Dr. Osler showed a case of typhoid fever in which there had been four genuine relapses.

Baltimore Deaths.—For the week ended November 9 there were 181 deaths, 3 being from typhoid fever, 9 from pneumonia, 4 from diphtheria, and 28 from tuberculosis.

State Examinations.—At the semi-annual state examinations for license to practice medicine 28 persons presented themselves, 3 of whom were women and one colored.

Johns Hopkins Historical Club.—At the meeting of this club November 11 papers were read by Dr. John Turner, Jr., on "Ancient Anatomists," and by Dr. Eugene F. Cordell on "The Medicine and Doctors of Juvenal."

Personal.—Dr. P. G. Wooley, Baltimore, has been appointed research fellow in pathology by the faculty of medicine of McGill University, Montreal, and will assist Dr. Adami, his especial work being the discovery of means to combat infectious diseases.

Addition to St. Joseph's Hospital.—Two new wards which have been added to St. Joseph's Hospital, Baltimore, were opened November 7. The funds for one building were raised by the Ladies' Auxiliary, and for the other by a bequest from the late Louis Doda. One ward is for the use of colored patients.

Medical Classics Donated.—A prominent member of the Medical and Chirurgical Faculty has presented to the library about 100 volumes of medical classics purchased in Amsterdam last summer. The oldest work is a Celsus of 1497, and there are five editions of Hippocrates, Oribasius, Rufus of Ephesus, Willis, Boerhaave, Jenner and others.

MASSACHUSETTS.

Epidemic Disease.—Fitchburg is threatened with an epidemic of typhoid fever and Danvers has more than 100 cases of measles.

New General Hospital.—Dr. Charles H. Cogswell, Boston, has purchased the Langwood Hotel in the Middlesex Falls Reservation and will establish a general hospital there.

Personal.—Dr. L. R. Bragg, Gloucester, has located in Webster.——Dr. George K. Blair, late interne at the New York Hospital, has established himself in practice in Salem.——Dr. Charles F. Canedy, Shelburne Falls, has decided to open an office in Greenfield.

Resolutions.—At the regular bi-monthly meeting of the Berkshire District Branch of the Massachusetts Medical Society at Pittsfield, October 31, resolutions of respect were offered to the memory of Drs. Thomas Riley and Daniel E. Thayer, deceased members of the society.

MICHIGAN.

Doctor Fined.—Dr. Albert H. Steinbrecher, Detroit, was fined $10 and costs for neglecting to notify the Board of Health of a case of scarlet fever for 48 hours.

Conference of Health Officials.—The next general conference of health officials in Michigan will be held in Ann Arbor, November 21 and 22. An invitation has been extended to manufacturers of formaldehyde apparatus to attend and exhibit their disinfectors.

Mortality in State During October.—There were 2548 deaths returned to the State Department for the month, corresponding to a death rate of 12.6 per one thousand population. The number of deaths returned for the month is 338 less than the number of deaths registered during the preceding month, and is 269 less than the number returned for October, 1900. There were 444 deaths of infants under 1 year of age, 167 deaths of children aged 1 to 4 years, inclusive, and 674 deaths of persons aged 65 years and over. Important causes of deaths were as follows: Pulmonary tuberculosis, 158; other forms of tuberculosis, 31; typhoid fever, 88; diphtheria and croup, 49; scarlet fever, 18; measles, 2; whooping cough, 5; pneumonia, 143; diarrheal diseases of infants under two years of age, 158; cancer, 126; accidents and violence, 190. There were two deaths from smallpox.

MINNESOTA.

Dr. Emil G. Geist, St. Paul, formerly house physician of St. Joseph's Hospital, sailed for Europe, October 31.

New Hospital.—St. John's Hospital, Springfield, which was built this past year at a cost of $16,000, was dedicated on October 27. The hospital will be under the management of the Lutheran deaconesses, is modern in construction and is well equipped.

Smallpox Increases.—The fortnightly report of the State Board of Health shows 144 cases of smallpox as compared with 137 for the previous two weeks. The greater number of cases are reported from Moorhead and Crookston and vicinity. Clay county reports 26; Polk, 22; Otter Tail, 21; Norman, 12; Murray, 8; Pope, 7; Fillmore, 13; Lyons, 7; Winona, 5, and Red Lake, 6.

MISSOURI.

The Missouri Baptist Sanatorium, St. Louis, has been given $75,000, which will be sufficient to pay its indebtedness and leave an endowment of $32,000.

Health Department Hampered.—The Municipal Assembly of St. Louis has declined to appropriate $10,000 asked for by

the Health Department for salaries of sanitary officers, inspectors and fumigators.

Did Not Find Tetanus Bacilli.—C. A. Snodgrass, the bacteriologist, employed by the St. Louis Health Department to examine the antitoxin which was prepared by the city, reports that no tetanus bacilli were found by him in the samples of August 24. These samples were taken from the same serum that was used in the fatal cases.

Personal.—Dr. E. H. Brumbaugh has entered on his duties as superintendent of the Ensworth Hospital, St. Joseph.—— Dr. Charles F. Greene, Poplar Bluffs, has been appointed local surgeon of the Southern Mississippi and Arkansas Railroad.—— Dr. Elias B. Roe, Crab Orchard, has moved to Orrick.——Dr. Charles H. Lester, Kansas City, has been seriously ill with an infected hand, but is now improving.

MONTANA.

Dr. Albert Butler, Carbonado, has located in Red Lodge.

C. A. Baxter, Butte, was fined $100 and costs, October 23, for practicing medicine without a license.

Smallpox has broken out simultaneously in several localities in Carbon County.

Successful Candidates.—Of those who applied for examination for license to practice, at the recent meeting of the State Board of Helena, 17 passed, and 1 was refused license on account of unprofessional and dishonorable conduct during the examination.

Butte is credited by the Bulletin of the Department of Labor with having the highest death-rate from pneumonia of any city in the United States with over 30,000 population. Its death rate from typhoid fever was within one of the lowest, and it had no malaria.

Typhoid Fever.—The disease is apparently under control in Red Lodge. The Great Falls Board of Health has reported that the cases of typhoid fever are due to the turning up of so much new ground by the boulevarding and improvements going on, rather than to the use of infected milk. It calls attention also to the failure of proper sewerage and the neglect of property owners to connect their houses with existing sewers.

NEW JERSEY.

Dr. Emery Marvel, Atlantic City, has gone to Vienna for four months.

Smallpox.—Three cases of smallpox were discovered in one day, at Newark, one of which, it is alleged, was concealed from the authorities.

NEW YORK.

Smallpox.—A number of cases of smallpox have been reported at Niagara Falls.

To Increase Lunacy Examination Fee.—The physicians of Wayne County have presented a resolution before the Board of Supervisors, asking that the fee for lunacy examinations be raised from $5 to $10.

Craig Colony Prize Awarded.—At a meeting of the Board of Managers of Craig Colony, October 8, the report of the Prize Committee was approved, and the prize of $200 was awarded to Professor Carlo Ceni of Pavia, Italy. The successful essay, the title of which is "Serotherapy in Epilepsy," will shortly be published.

Fifth District Branch of the State Medical Association will hold a special meeting at the Palatine Hotel, Newburg, N. Y., on Wednesday afternoon, November 20. Important papers will be presented by Dr. John B. Deaver, Philadelphia, and Drs. Chas. E. Quimby and William Rice Pryor, New York. These papers will be followed by discussions. A large attendance of physicians is anticipated from among the members residing in the Fifth District Branch, which includes the Counties of Dutchess, Kings, Nassau, New York, Orange, Putnam, Queens, Richmond, Rockland, Suffolk, Sullivan, Ulster and Westchester. For the accommodation of the physicians in Manhattan who wish to attend this meeting a special car will be attached to the 11:50 a. m. train, on the West Shore Railroad, Weehawken Ferry. Luncheon will be served at Newburg at 1:45 p. m. The meeting is called for 2:30 p. m. All physicians are cordially invited to be in attendance.

Buffalo.

Dr. Earl G. Danser has been elected coroner of Erie County.

Diphtheria has again appeared in the public schools, 13 children were found to have the disease in a latent form, proven by cultures made in Public School 59.

The Exposition Hospital on the Exposition grounds has been closed permanently. A surgeon will be stationed in the service building to care for any injured workmen employed on the demolition of the buildings.

Smallpox.—Health Commissioner Wende is preparing a communication for transmission to the aldermen, giving a detailed account of the history of the 13 cases of smallpox which have appeared in the city during the summer and fall. The patients now under treatment for the disease are doing nicely, and there is no imminent danger of an epidemic.

Endorsement of the Health Department.—Petitions are being circulated by prominent Buffalo physicians asking for the re-appointment by Mayor-elect Knight of Health Commissioner Wende and Assistant Health Commissioner Green. Their appointment is petitioned for irrespective of political affiliation; the department of health under the present management has been conducted upon strictly non-political principles with the objects of maintaining the public health, reducing mortality and protecting our industries.

New York City.

Coroner Enjoined.—The Supreme court has handed down a decision restraining Coroner Zucca from trying Coroners' Physician Dr. Hamilton Williams, and removing him from office. The court holds that the power of removal is expressly vested in the Board of Coroners, and not in any individual member.

Memorial Hospital not to be Erected.—The Skene Hospital for self-supporting women as a memorial to the late Dr. A. J. C. Skene, has been dissolved by order of the Supreme court of Brooklyn, N. Y. The sum needed was $300,000, but of the $23,000 subscribed only $3261 were paid, and this last amount is to be distributed among the contributors.

Bellevue Hospital has just lost by death a man who enjoyed the distinction of being the oldest patient in that institution. His name was Thomas H. Robinson, and he had been constantly there since Feb. 21, 1881, suffering from a spinal affection brought on by a railroad injury. He made himself very useful about the hospital, and gained many friends there.

Scarlet Fever Epidemic Threatened.—Public School No. 99, at Throgg's Neck, Burough of the Bronx, was closed November 9, because out of the 400 pupils between 30 and 40 were reported sick with a mild form of scarlet fever. The infection was traced to a child who returned to school after an illness of some weeks and a course of "home treatment" without a diagnosis.

Midwife's Negligence.—Miss Julia O'Neill, a midwife, has been arrested on the charge of having failed to register as a midwife, and of having neglected to call in a regular physician to see a newly-born infant who was suffering from a severe form of ophthalmia. As the result of her negligence the child became totally blind. This occurred last December, but the case only came recently to the knowledge of the authorities when the baby was brought to the Manhattan Eye and Ear Hospital for treatment.

The Incubator Troubles.—A case that has come up in the sheriff's office brings out some interesting facts connected with the baby incubator exhibit at the Pan-American exposition. This exhibit was in charge of three partners, and one of these now claims that the other two partners have hidden the apparatus and have secreted the proceeds of the show. The assertion is made that the exhibit in Buffalo brought in $125,000, and that instead of receiving one-fourth of the gross proceeds he has been paid only $14,000. The plaintiff also declares that it is the intention of the other partners to still further defraud him by taking the exhibit without his consent to the exposition to be held in St. Louis.

Ward vs. Hospital.—The case of Helen D. Ward against St. Vincent's Hospital has been passed upon once more, this time by the appellate division. It will be remembered that the plaintiff brought suit because she had been severely burned by a hot water bottle through the negligence of a nurse, and that the case has already been tried twice. Judgment on the first trial was reversed because the trial justice misconstrued the action to be one in tort and not on contract. A judgment was awarded the plaintiff. The appellate division now orders a reversal because the trial judge refused to charge the jury, as requested by defendant's counsel, that the defendant was not bound to assign to the plaintiff the best nurse in its hospital, but only a nurse who was ordinarily well trained and ordinarily competent and skilful.

OHIO.

McKinley Hall.—The new chapel and amusement hall at the State Hospital for the Insane, Massillon, which is to be dedicated November 21, is to be called McKinley Hall.

New Hospital Needed.—Dr. Walter W. Brand, health officer of Cleveland, advises the erection of a new isolation hospital to cost $3500, the old building to be used as a detention hospital for suspects.

Personal.—Dr. John E. Hill, Tallmadge, has moved to Akron.——Dr. William T. Howard, Jr., has been appointed city bacteriologist of Cleveland.——Dr. Charles A. Foster, Washington Court House, who is about to locate in Newark, was given a farewell dinner by his professional brethren, October 28.——Dr. Howard W. Quirk, Cleveland, has moved to Jersey, Licking County.

Dr. William H. H. Nash, Columbus, an old and esteemed practitioner, who through the infirmities of age and failing eyesight is no longer able to continue his professional work, and who has no relatives or means of support, has been admitted to the Home for the Aged through the good-will of the Columbus Academy of Medicine, which has authorized the managers of the Home to draw upon it for $150, and which has pledged itself to the payment of all moneys required to provide him with a home for the rest of his life.

PENNSYLVANIA.

Vaccinate Railroad Employes.—Dr. Edwin C. Town, medical examiner and chief surgeon of the Pennsylvania Railroad Company, has, within the last two weeks, aided by assistants, vaccinated 4200 of the company's employes, and reports that 80 per cent. are successful.

Contagious Diseases.—Diphtheria is epidemic near Ruffsdale, where 80 cases are reported and where the public schools have been closed. At Greenfield, Erie County, seven have died; many are ill. The disease has appeared at Thiel College, Greenville.——Smallpox has appeared at Bryn Mawr College.

Personal.—Dr. John J. Cannan, Williamsport, has returned to Bradford, and resumed practice.——Dr. William E. Keller, Scranton, has been appointed a member of the medical staff of the Lackawanna hospital.——Dr. Frederick G. Ibach, Mauch Chunk, has moved to Tamaqua.——Dr. Robert M. Kennedy, Pottsville, past assistant-surgeon, U. S. Navy, has been appointed surgeon and has been assigned to duty at Norfolk, Va.

For Poor Consumptives.—The board of managers of the Free Hospital for Poor Consumptives, Philadelphia, makes the following appeal for support: "We have 40 patients, in various hospitals, for each of whom we pay $5 a week. We have 2 female patients in the Adirondacks, for each of whom we pay $7 a week. We have 20 male patients in our camp at White Haven, who stand us about $5 a week per patient. Our expenses aggregate about $1300 a month. The state gives us about $400 a month, and we are compelled to raise $900 a month from the charity of the people. Our treasury is empty. We have no money to pay our October bills. A word as to our work. The 40 dying patients are given a decent place in which to die, and we are abating 40 centers of distribution of tuberculosis. Ninety per cent. of the 30 cases at White Haven we believe will recover, and return to lives of usefulness. In August their gain was twelve pounds per patient; in September, seven pounds per patient. Four patients have returned to work. It is certain that tuberculosis can be cured, but money must be provided."

TENNESSEE.

Dr. Robert W. Dulaney, Jonesboro, has been appointed physician for the Southern Lumber Company in Johnson County.

Franklin Fined.—"Dr." J. C. Franklin, Nashville, found guilty of sending obscene matter through the mails, was fined $1700 and costs, October 25.

Memphis Hospital Medical College opened, November 1, for the year, with an initial registration of 461, the largest enrolment in the history of the institution. Dr. Hugh Spencer Williams delivered the opening address.

WISCONSIN.

Milwaukee Hospital benefited to the extent of more than $1000, on annual donation day, November 7.

Must Build Separately.—The city attorney of Milwaukee and district attorney of Milwaukee County have decided that under the law the city and county have no right jointly to erect an isolation hospital.

Post-Graduate School in Milwaukee.—Drs. William H. Earles, Walter H. Neilson and Warren B. Hill, Milwaukee, have incorporated the Milwaukee Post-Graduate School and Polyclinic, with a capital stock of $50,000.

Smallpox.—Marshfield has 9 cases; 3 new cases have developed in Ashland, where the Catholic schools have been closed; 6 cases are under treatment at Superior; a case has been reported at Prentice; 2 new cases are in quarantine at La Crosse; at East Wrightstown the village schools have been closed because of an outbreak of the disease; Kaukauna, Sherwood and Stockbridge have cases; many cases are occurring around Wausau, necessitating closure of schools; at Little Chute more than 50 cases are under treatment; De Pere reports 6 cases of the disease.

GENERAL.

Smallpox.—The United States Health Reports give 262 as the number of cases of smallpox in the country for the week ending November 9.

Army Medical School.—The 6th session of this institution began November 14. The instruction is given in the Army Medical Museum and Library, in Washington, D.C. Nineteen student surgeons reported for instruction at the school and the course will last five months.

Plague in San Francisco.—Another death from bubonic plague was reported October 31. Dr. M. J. White, of the Marine-Hospital Service, diagnosed the case. The lay press states that the Chinese, instigated by the state authorities, have begun proceedings against the City Board of Health to have the quarantine removed.

CANADA.

Convictions Against Druggists.—Some time ago several druggists of Toronto were fined in the police court for practicing medicine without the proper qualifications. Appeals were taken to the Court of Sessions with the result that all have had their convictions quashed.

Smallpox in Manitoba.—The epidemic of smallpox in the province of Manitoba has been more extensive than at first supposed. There have been 8 or 9 cases at Hartney, 6 or 7 at Deloraine, 4 at St. Andrew's, 2 in Winnipeg, one at Neepawa and one at the Selkirk Asylum, a case which proved fatal.

Dr. Philip Weatherbe, Halifax, has just completed his course in medicine at Edinburgh University. He is at present on a visit to Canada and intends taking a commission in the Indian Army Medical Corps. He has had an experience of nine months' service in South Africa with the Scottish Hospital Corps from Edinburgh.

Laval University.—The annual report of Laval University, just issued, shows that encouraging progress is being made in this institution. The attendance last year in all the faculties was 719, an increase of 114 on the preceding year. There were graduated in medicine 42 students. Dr. Etienne Larin has recently been appointed assistant professor of clinics at the Hotal Dieu Hospital.

Toronto Sanitarium.—The Local Board of Health has again recommended to Council the submitting of a by-law to the electorate on January 1, for $50,000 for a free consumption sanitarium, the city to hand over the said sum when a like amount has been paid to the city treasurer in trust. The sanitarium is not to be situated farther than 40 miles from the city and is to care for all classes of patients. Action will also soon be taken against the spitting nuisance in the way of placing notices in public places.

A New Disease.—The books of the Toronto osteopaths recently impounded by the Crown show that these "practitioners" do not strictly confine their work to their own particular pathy. In the list of diseases which they have "treated" in Toronto, rheumatism, typhoid fever, pin worms, Morton's disease, etc., appears one set down as "rumbling in the head, especially in bad weather or poor health." If the alienists wish to keep abreast of the times, they will have to get after the pathology of this new disorder.

Dr. C. A. Hodgetts, Toronto, who for some time has been associated with the Ontario Board of Health as a special medical inspector, has been appointed permanently to the position of medical inspector to the unorganized districts of Ontario. There is a population of 100,000 scattered along a frontier of some 6000 miles of railway, lake and river; it will be Dr. Hodgetts' special duty to see that the recent regulations of the Health Department with regard to lumber camps, railway-construction camps, etc., be carried out.

Osteopathy Dangerous.—The Ontario Medical Council is getting after several of these "practitioners." Two of them recently appeared before a coroner's jury in regard to the death of a young lady through the bursting of a blood vessel while undergoing treatment for a large goiter. The jury in this case recorded their verdict, that they believed this sort of practice unskilful and dangerous, and that strict laws should be enacted which would put an end to this dangerous practice, and others of kindred nature which they believe are all too common in Toronto.

Eddyite Convicted.—A trial which has excited a great amount of interest in Toronto was that which ended a few days ago in the conviction of a father for manslaughter, who failed to provide proper medical attendance for his infant son that died from diphtheria. The case is to go on to the Appeal Court in order to ascertain whether medicine is a necessary of life according to the Canadian Criminal Code. In connection with this trial there were several amusing incidents, one very steadfast in the faith asserting that he, by his prayer, could escape a bullet from the Crown Prosecutor, provided the latter directed one at him. Of course the laugh was on the Crown Prosecutor, who had to declare that he was a good shot in spite of the faith of the witness.

The Indian Medicine Men of British Columbia.—Dr. J. C. Spencer, medical missionary to the province of British Columbia, says that the Indian medicine men are the great foes of the missionaries. They administer no medicines, but try to drive out the evil spirits of the disease by taking the medicine themselves. If one fails he calls in a second, and when all have failed, they initiate the sick man into the mysteries of their practice, so that he may make friends with the evil spirits himself. There is a hospital at Fort Simpson on the Pacific Coast which does an immense amount of good not only to the Indians but to Orientals as well. This hospital receives $1,500 annually from the government. It is well equipped and supplied with three nurses.

Site for Sanitarium for Tuberculosis.—The alarming increase in the number of deaths from tuberculosis in the Province of Quebec during the past two or three years has resulted in a number of Montreal physicians making an effort to establish a sanitarium nearer the city. The Fathers of the Holy Cross who have charge of the Cote des Neiges College, have offered a large tract of land on the north side of the second mountain; and the physicians consider the situation all that could be desired for a consumption hospital. A leading citizen has offered to endow the institution sufficiently to meet the expenses of running it, provided the provincial government erect the building. The following shows the death rate and the annual increase: 1894, 2664; 1895, 2791; 1896, 2826; 1897, 3079; 1899, 3487; 1900, 4782.

Research Laboratory Promised.—The free hospital now in course of erection near the Muskoka Cottage Hospital will soon be ready for the reception of patients. The main building is the gift of Mr. W. J. Gage, of Toronto, and the estate of the late Mr. Hart A. Massey. It is located in a beautiful park of 56 acres within half a mile of the town of Gravenhurst. Fifty beds for Toronto's poor are being provided; the Grand Trunk Railway will carry free of charge 100 patients each year to and from the institution. All in excess of that number will be carried at half rate. Physicians and nurses will also be carried free of charge. This hospital will be for those in the earlier stages of consumption; the National Sanitarium has purchased a fine site near Toronto at a cost of $30,000 for advanced cases. It is understood that the late Mr. W. E. H. Massey has bequeathed $30,000 for a research laboratory in connection with the Gravenhurst institution.

FOREIGN.

Smallpox in Panama.—The Marine-Hospital Service reports 300 cases of smallpox in Panama, Colombia; the city has a population of 30,000.

Plague in Great Britain.—The last case of bubonic plague in Glasgow was reported and placed in the hospital November 1. The authorities consider that the disease has been stamped out. At Hull a suspicious death occurred on a steamship, believed to be due to the plague.

Professor Antona, Italian senator, sued the authors of a defamatory article published in an Italian paper, accusing him of the responsibility for the death of a patient. The courts decided in his favor and condemned the defendants to two years of imprisonment and a fine of 2000 lire.

Virchow's Pathologic Institute.—The newly-opened pathologic institute at Berlin is Virchow's special pride. He announces that he will personally conduct a group of twenty colleagues through it every Saturday afternoon. Applicants for the privilege inscribe their names beforehand.

Deaths Abroad.—The professor of forensic medicine at Madrid, Dr. T. Yanez y Font.——Dr. J. H. Chievitz, professor of anatomy at Copenhagen.——Dr. G. Naeher, one of the leading physicians of Munich, a pioneer in the effective co-operation of the members of the profession in the "battle of the clubs."

The Amalgamation of the Scientific Institutes at Hamburg.—The various scientific institutes at Hamburg are to be grouped like a university, and the directors and lecturers will form the faculty, issue reports, etc. The official title of the faculty will be the "Professorenconvent" of the Scientific Institutes. Besides promoting individual research, the institutes will carry on research desired by outside scientists and advise in scientific matters generally. Hamburg has long been wishing for a university of its own, and this step is in the line of the consummation of its desires.

Nothnagel's Sixtieth Birthday.—The *Wiener Klinische Rundschau* devoted its issue of October 13 to a souvenir number in honor of Nothnagel's 60th birthday. It contained twenty-six original articles by his pupils and friends and a full-page reproduction of the fine oil portrait which was hung with appropriate ceremonies in his amphitheater, at Vienna, the "first internal Klinik," when he resumed his lectures. He had declined this homage and spent the actual birthday out of town, but his friends were not to be deprived of the opportunity to do him honor.

German Congress of Physicians and Scientists.—The seventy-third annual congress of the German society of "Aerzte und Naturforscher" met this year at Hamburg with a large attendance. The principal addresses were on Herz's discovery of electric waves; the chemical provisions of the cell; the problem of fecundation; importance for chemistry of electric methods and theories; the natural defensive forces of the organism; the latest developments in regard to ions, electrons, etc.; the protecting substances in the blood, and the present status of the theory of the descent of man. The next congress will be held at Carlsbad in September, 1902.

LONDON LETTER.

The Diminution of the Birth Rate.

"The increasing sterility (infecundity would have been a more accurate word) of American women," discussed by Dr. Geo. J. Engelmann and others at the last meeting of the American Medical Association (THE JOURNAL, October 5, p. 890) has its counterpart in this country, though the phenomena are not nearly so striking. At the recent meeting of the British Association—not a medical but a scientific body, which meets annually to discuss the scientific problems of the day—the diminution of the birth rate in such widely separated English-speaking lands as England, the United States and Australia was discussed. Mr. Edward Cannan showed that the average number of children to a marriage in the United Kingdom has fallen from 4.36 in 1881-84 to 3.63 in 1900. The decline is probably due to the artificial prevention of conception—a practice which appears to become more and more prevalent.

Smallpox Increase in London.

A somewhat serious increase in the number of cases has just occurred. On October 24 no less than 11 fresh ones were notified—making 168 under treatment. On October 26 no less than 13 fresh cases were notified—the largest number received in one day during this outbreak. The deaths from the disease since the beginning of the outbreak are as follows: Week ending September 28, 5; October 6, 3; October 12, 3; October 19, 11. The neglect of vaccination is a great difficulty in checking the outbreak. Public bodies such as school boards, boards of guardians for the poor and vestries are often hostile or indifferent to vaccination and will not give the public vaccinators facilities for revaccination of those under their charge.

A New Vaccination League.

To counteract the anti-vaccinationists, who are a strong body in this country, a vaccination league has been inaugurated, and it is proposed to start an active campaign in London for the purpose of spreading knowledge on lines antagonistic to the Anti-Vaccination League. Already it has received the adhesion of many influential members of the medical profession: Sir Alfred Garrod, Professor Stewart and Mr. Jonathan Hutchinson, who was one of the leading members of the Royal Commission on Vaccination. It is intended that steps shall be taken to enforce the vaccination law in certain districts of London.

Literature will be distributed and a magazine in the interests of vaccination will probably be started. Lectures may also form a feature of the league's propaganda.

Hematuria in Childhood.

At the Harveian Society Mr. Campbell Williams read a short but very exhaustive paper on this subject. He pointed out that in many cases of calculus hematuria was absent, the only diagnostic signs being dysuria and frequent micturition. The first symptom of renal tuberculosis might be copious hematuria. Caruncle of the urethra was an occasional cause of hematuria in female children. In scurvy-rickets hematuria might precede the usual osseous and oral manifestation of the disease. In hemophilia, also, hemorrhage from the bladder or kidneys might be the primary symptom.

Irish Vital Statistics.

The annual report of the registrar-general for Ireland is of a hopeful character, though the drain on the population of the country which has been going on for the last half century still continues. During the last decade both the marriage and birth rates have considerably increased, the former from 4.45 per 1000 to 4.96, and the latter from 22.3 to 23.1. The death rate shows a downward tendency, being 17.7 in 1899 compared with 18.2 in 1890. Emigration has fallen from 13 per 1000 in 1890 to 9.2 in 1899. The average during the decade was 9.8. Ireland is remarkable for the small number of illegitimate births. Comparing the provinces the percentage of children born out of wedlock in Ulster was 3.6, in Leinster 2.5, in Munster 2.5, and in Connaught 0.5. Cancer is on the increase in Ireland as elsewhere. The rate for last year was .06 per 1000, an increase of .02.

Correspondence.

Cigarettes.

FT. ROBINSON, NEB., Nov. 9, 1901.

To the Editor:—The statement that "cigarettes are the least dangerous form of tobacco," as quoted from Dr. Kuborn's Report to the Royal Medical Academy of Belgium, as noticed in the Paris Letter in THE JOURNAL of October 12, seems to challenge justifiable inquiry. A very large percentage of the United States troops who have returned from Cuban service are addicted to this mode of tobacco-using, and—while the *modus operandi* of cigarette smokers may differ in different parts of the globe—the above mentioned quite generally inhale the smoke for several seconds, and then slowly expel it through the nostrils. By that time it seems to have parted almost entirely with the, at least grosser, products of combustion, as is apparent from its color, and as one might expect from its long and intimate contact with the moist surfaces of the lungs, bronchi, fauces, nares, etc., the opportunity for the absorption of the nicotin is much greater than in ordinary smoking. Further, as I have frequently seen done, if, before inhalation, this smoke is forced from the lips rapidly over the nail of the thumb, or better still, over a piece of cool glass or porcelain, a fan-shaped, brown stain will be deposited, rank in odor and oleaginous with nicotin. At each inhalation the major portion of this tobacco essence is directly absorbed by the mucous tissues and must tend to produce nicotinism far more rapidly than is possible with any other method of tobacco-using.

E. W. BLACK.

St. Luke's Hospital.

NILES, MICH., Sept. 30, 1901.

To the Editor:—My attention has been called to an editorial in your issue of the 7th inst. concerning the so-called St. Luke's Hospital of this city. I see you are not fully acquainted with the methods and managements of this institution, and, although I know as much as anyone on the outside, probably, I can not say that I know all about it.

I believe this so-called hospital commenced operation here in the fall of 1896, but its work has always been conducted with as much secrecy as possible, and it was not until it had been doing business some months that we learned of its methods. Our State Board, at its meeting in January, 1899, considered the matter quite at length, but no law under which proceedings could be commenced could be found and nothing was done.

St. Luke's is organized and incorporated under the laws of the State, and it is capitalized at $10,000, 400 shares at $25 each. Of these "Dr." Charles W. H. B. Granville, of Niles, Mich., had 196, "Dr." Arthur C. Probert, of Washburn, Wis., 203, and Annabelle Granville, of Niles, Mich., 1.

Under this law St. Luke's issued "certificates of merit," as they were termed on their face, although in appearance diplomas, and the name of Nicholas Senn, as well as many other men of good standing in the profession, was used to sell them.

I do not think St. Luke's Hospital ever really had a patient in it, at least not one who stayed over 24 hours.

In order to reach this institution, the Legislature of 1899 passed Act No. 151, entitled "An act to specify the sources of authority for the issuing of medical diplomas," etc. Since this time I am not aware that St. Luke's has issued anything except what they term "certificates of stock," which have the appearance of diplomas, however, and it seems to us here very laughable that they should be able to sell such things to anybody in their right mind. If you know of any infringement of the laws of the State by this institution, I would like to know of it.

You speak of "Dr." Granville as the head of the concern. He was never more than a figurehead. Although no state law could reach the institution, one of Dr. Granville's numerous wives found him out, and, after being put under $500 bonds, he left for parts unknown, and St. Luke's paid the $500; so he is only a memory.

"Dr." Probert has been the real head at all times. He has held positions of honor, influence and trust, in business, politics and religion. He is a nice appearing man and a particularly dangerous one. . . . . At the present time proceedings for his extradition from this State by the Governor of Indiana for defrauding the inhabitants of Bourbon, Ind., and vicinity, are in progress. He is generally described by those who know him well as a "bird."

Respectfully yours, FRED R. BELKNAP, M.D.
Member Michigan State Board of Health.

A Battle with the Clubs at Ludington, Mich.

The lay press has contained recently accounts of a club or society organized in Ludington, Mich., for the purpose of getting cheap medical treatment. The newspaper accounts are all similar to the following, clipped from a Chicago paper:

"Ludington (Mich.) doctors began it with something termed a doctors' trust. Now Ludington has a Health Association, with one community doctor, supported by monthly dues from association members, who number 240 families, each paying 50 cents a month. As a result, one doctor, who, at least, is named Best, is drawing $1,800 a year salary for being ready at all hours and seasons to respond to Health Association calls. A woman doctor with the Scandinavian name of Hoglund forced the measure. Dr. Hoglund went to Mason County as midwife and broke the union scale of Mason County physicians. The doctors prosecuted her. The Swedish Aid Society espoused her cause and helped her fight. The Ludington Health Association was the fruit of the bitterness engendered. Dr. Herbert M. Best of the Detroit Medical College was chosen as physician to the association. His only pay is the 50 cents monthly which each household in the association pays in for his services. There are 240 families now in the association, and the number is growing rapidly. When Dr. Best arrived in Ludington he was waited upon by members of the Mason County Medical Association and importuned to join. As a "contract" physician, however, he discovered that he was not eligible to membership. Then he was boycotted by the "regular" physicians. So far as Dr. Best has gone with his work he is pleased. He is sure of his comfortable salary for a country doctor, and he has found no disposition on the part of the members of the association to abuse their privileges. In calling on a family he simply asks to see the membership card. Last week he averaged only three office calls and two visits

to residences daily. He says when the busy season of winter comes on if he is worked too hard the association will get an assisting physician. In the meantime, when Dr. Best, who is young, has to call in consulting physicians in a case, he has to go to Grand Rapids for the talent."

In reply to a request for information in regard to the matter, the following has been received. It seems that both of the doctors are Canadians, and graduated from a Detroit college this year:

LUDINGTON, MICH., Nov. 9, 1901.

To the Editor:—The information you request takes us back to 1900, when the Michigan law took effect, requiring all practitioners of medicine to re-register. On this being accomplished all the physicians in Mason County legally working, except one, met and formed the Mason County Medical Association, under the same by-laws as govern all other medical associations and for the same purposes and to protect themselves against the deadbeats, who are as thick here as in other places

According to law, and by request of the State Board of Registration, they forwarded the names of all those illegally practicing medicine to the prosecuting attorney. Among these occurred the name of a woman that has lived in Ludington for years. She received legal notice to stop practicing midwifery, but refused to obey, claiming the right to continue on account of some paper she holds from Sweden. The others notified stopped, at least for a time. One newspaper here abused, lied about and scandalized the Mason County Medical Association, calling it a trust, etc., and supporting the Swedish Aid Society in their view of the prosecution of the case. At the present writing the prosecuting attorney has not attended to the case.

You see that all the physicians could do would be to protect the people against her bad work and injuries (and they are many) by supplying evidence or being witnesses in some sad cases well known to the profession here, and they will testify when the case is reopened.

This, no doubt, was used as an excuse for the formation of the so-called "health association" by the editor of the paper referred to above (who is one of their officers) and the other leaders, aided by a false report circulated by them that we had doubled our charges since organizing, also that we would attend no one owing a bill until every dollar owed any member was paid. If true, a brutal proposition, but there is not a word of truth in it. The facts are: the fees were unchanged from the prices charged for years, but if a family or person is on the "deadbeat list" they have to pay any doctor of the association the new call, or visit, cash, and all subsequent visits cash. This is the only restriction placed against anyone on the "D. B. List."

Several doctors in Ludington were offered the chance to act with, or for the so-called "health association" against the other ten physicians in the city, but all refused to entertain such an unfair proposition.

Two outsiders came here to see about it, but would not enter into such an agreement; the [illegible]d, Dr. Best, a 1901 graduate of Detroit College of Medicine, came under a guarantee of $50 per month. The Medical Association feeling that no one acquainted with the circumstances would continue to act with a body of people under such false statements and conditions, invited Dr. Best to our regular supper and meeting, there explaining the professional status and all facts relating thereto. We asked him to join with us, assuring him that we would do all that we could to assist him when occasion demanded. But if he continued with the "health association" under existing circumstances we could not in justice to ourselves have anything professionally to do with him. He decided to stay with the "health association," and induced another young man of the same college and class (May 9, 1901), whose name is Dr. George V. Oill, to come here and associate with him. Their success has not been good, and even in the two months numbers have left the "health association" and come back to their regular physicians; a large number we do not wish to return for their names form a part of the "deadbeat list."

The Mason County Medical Association thank you for the interest taken, and unite with you for professional integrity.

We are, dear sir, yours respectfully, A. P. McConnell, President; Samuel C. Burland, Secretary pro tem.; W. H. Taylor, and fourteen others.

Association News.

New Members.

The following is a list of new members for October:

ALABAMA.

McKinney, E. P., Kellyton.
McWhorter, G. T., Riverton.

ARKANSAS.

Kinsworthy, J. H., Little Rock.
Rush, J. O., Forrest City.
Cooper, St. Cloud, Fort Scott.

Book Notices.

NERVOUS AND MENTAL DISEASES. By Archibald Church, M.D., Professor of Nervous and Mental Diseases, and Head of Neurological Department, Northwestern University Medical School, and Frederick Peterson, M.D., Chief of Clinic, Department of Nervous and Mental Diseases, and Clinical Lecturer on Psychiatry, Columbia University. Third Edition, Revised and Enlarged. Cloth. Pp. 870. Price, $5.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

This third edition of Church and Peterson's work has, as they state in their preface, been thoroughly revised, both with additions to its subject-matter and in the rearrangement wherever necessary. New illustrations, new tabular matter, and diagrams for assistance in the solution of diagnostic problems have been added. These changes bring the book fairly up to date, and it will continue to be the favorite text-book that it has been since its first appearance. In the main, however, the text is unchanged and there have been no extensive additions or new diseases noticed. We still think the second part by Dr. Peterson, though admirably written and convenient for the student, is hardly equal in its arrangement and its recognition of the latest acquisitions on the subject to the first part furnished by Dr. Church. Dr. Peterson holds to the old-fashioned arrangements of insanity to a great extent and does not fall in with the modern tendency to accept the changed views that have been recommended by Kraepelin and others in regard to certain important types. However, his descriptions are, in the main, very good, and for a convenient text-book of insanity it will be likely to hold its own. Like many other writers he recognizes cerebral spinal syphilis as distinct from general paralysis, notwithstanding the close resemblance between the two, but we hardly trust the parallel column comparison between the two diseases, and we think the student would be misled if he diagnosed or refused to diagnose general paralysis on account of some of the distinctive features that are here pointed out. The illustrations are numerous and in the main admirable. Taking the book as a whole, we can say nothing that is not commendatory.

A MANUAL OF DETERMINATIVE BACTERIOLOGY. By Frederick D. Chester, Bacteriologist of the Delaware College Agricultural Experiment Station, and Director of the Laboratory of the State Board of Health. Cloth. Pp. 401. Price, $2.60. New York: The MacMillan Co. 1901.

The author of this book undertook the arrangement of all described species of bacteria in order to determine whether certain forms isolated by him from the study of the bacterial flora of cultivated soils were new forms. The labor was so great that it was thought best to embody the results in book form so that other workers might have the advantage of the results. The book serves principally the purpose of identification. The classification adopted is not claimed to be perfect, but the best one that could be made under the circumstances. From glancing at the index and the body of the work it is believed that Chester's work will prove to be a useful one in determining the identification of unknown bacteria. By its aid the pupil, as well as the advanced worker, will be able readily to determine the identity of bacterial cultures. The work will, therefore, be a useful laboratory manual. There is an interesting glossary of descriptive terms used in bacteriology, and the morphology and cultural characteristics of bacteria receive consideration in the first part of the work. The scheme for the study of bacteria given in the third chapter is certainly a valuable one, and if it were followed much greater clearness would result in the study and description of bacteria. The book can be recommended confidently to laboratory workers in general.

A TREATISE ON THE ACUTE, INFECTIOUS EXANTHEMATA. Including Variola, Rubeola, Scarlatina, Rubella, Varicella, and Vaccinia, with especial reference to Diagnosis and Treatment. By William Thomas Corlett, M.D., L.R.C.P. Lond. Professor of Dermatology and Syphilology in Western Reserve University. Illustrated by 12 Colored Plates, 28 Half-tone Plates from Life, and 2 Engravings. Pages viii-392. Sold only by Subscription. Price, Extra Cloth, $4.00 net, Delivered. Philadelphia: F. A. Davis Company. 1901.

The book by Dr. Corlett is the outgrowth of his own experience as a young physician beset with difficulties in the differential diagnosis of the acute infectious eruptive diseases. The dangerous, communicable nature of these diseases has so far rendered it almost impracticable to give adequate clinical instruction to medical students. It must be acknowledged that in the practical teaching of medicine, the shortcomings of the present methods are greater in the class of eruptive diseases than in any other. The photographic reproductions are excellent, especially those illustrating various forms and stages of smallpox. Some of the colored plates are also quite satisfactory. The book certainly fills a fairly well-defined place and will be found useful to student and practitioner alike. There is an interesting chapter devoted to the early history of eruptive diseases. The diseases considered are variola, vaccinia, varicella, scarlatina, rubeola and rubella. From the publisher's standpoint, the work does not leave much to be desired, although the binding might have been better.

PRINCIPLES OF SURGERY. By N. Senn, M.D., Ph.D., LL.D., Professor of Surgery in Rush Medical College, in Affiliation with the University of Chicago. Third Edition. Thoroughly Revised, with 230 Wood-Engravings, Half-Tones, and Colored Illustrations. Royal Octavo. Pp., xlv-700. Extra Cloth, $4.50 net. Philadelphia: F. A. Davis Company. 1901.

Senn's "Principles of Surgery" has been before the profession ten years, and is perhaps the best work which has come from this author's pen. It is so well known that a general review of it is unnecessary. There have been few changes made in this the third edition. We note a short chapter on Degeneration, and one on Blastomycetic Dermatitis. Also a few X-ray plates have been introduced illustrating some of the changes which take place in bone. Many of the later views on some of the questions in surgical pathology have not yet found their way into the book; for instance, in describing the white corpuscle of blood one is led to suppose there is but a single variety of leucocyte, and no mention is made of the various kinds which are present in the blood and the changes which they undergo in certain pathological conditions. Notwithstanding this fact the work is a very excellent one, and the best one in the English language which deals with this subject.

THE PRINCIPLES AND PRACTICE OF MEDICINE. Designed for the Use of Practitioners and Students of Medicine. By William Osler, M.D., Fellow of the Royal Society. Fourth Edition. Cloth, Pp 1182. Price, $5.50. New York: D. Appleton & Co. 1901.

Few books on medicine in recent years made a more favorable impression on first appearance than Osler's "Practice." The reason for this is not hard to discover; it was original, complete, scientific, but above all written in a charming manner. It appeared first in 1892 and in nine years four editions have been required. The edition just issued contains a more thorough revision than either of the preceding ones. The opening chapter on typhoid fever has been in the most part rewritten, and that on malaria has necessarily been recast to

accord with the present knowledge of the etiology and prophylaxis of this disease. The chapters on many of the other more common diseases have also been in part rewritten. Many diseases not mentioned in former editions have been considered in this one, making the book more complete than ever. It will continue to hold its position as one of the best text-books on the practice of medicine in the English language.

THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY. For Practitioners and Students. A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry and Kindred Branches, Including Much Collateral Information of an Encyclopedic Character, Together with New and Elaborate Tables of Arteries, Muscles, Nerves, Veins, etc.; of Bacilli, Bacteria, Micrococci, Streptococci; Eponymic Tables, Diseases, Operations, Signs and Symptoms, Stains, Tests, Methods of Treatment, etc. By W. A. Newman Dorland, A.M., M.D., editor of the "American Pocket Medical Dictionary." Second Edition, Revised. Leather. Pp. 770. Price, $4.50 net. Philadelphia and London: W. B. Saunders & Co. 1901.

The necessity for a second edition of this dictionary inside of eleven months is sufficient evidence to show the popularity with which it was received on its first appearance. The general arrangement of the words and their definitions is very satisfactory and the use of thin Oxford Bible paper and flexible covers has made it possible to produce a word book, full and complete enough for all ordinary use and yet so compact that it is but little larger than the ordinary abridged dictionary. For everyday use it is the most satisfactory of any published.

A TEXT-BOOK OF BACTERIOLOGY. By George M. Sternberg, M.D., LL.D., Surgeon-General, U. S. Army. Illustrated by Heliotype and Chromo-lithographic Plates and 200 Engravings. Second Edition, Revised. Cloth. Pp. 707. Price, $5.00. New York: Wm. Wood & Co. 1901.

Sternberg's text-book of bacteriology has for some time been the standard and all that is necessary to say of this edition is that it still fully represents the state of knowledge of the subject of which it treats. In this edition there have been added two new sections, one on Protective Inoculations in Infectious Diseases and one on the Bacteriology of Plant Diseases. It is impossible for the physician who pretends to keep in touch with modern medicine to get along without a text-book on bacteriology, and we know of none more deserving of recommendation than this one of Sternberg's.

AN INTERNATIONAL SYSTEM OF ELECTRO-THERAPEUTICS. For Students, General Practitioners, and Specialists. By Numerous Associated Authors. Edited by Horatio R. Bigelow, M.D., Permanent Member of the American Medical Association. Second Edition. Revised and brought up to date, with several New Departments, Embodying the Most Recent Developments of the Science. Edited by G. Betton Massey, M.D., Ex-President and Fellow of the American Electro-Therapeutic Association. Thoroughly Illustrated. Royal Octavo. Pp. x-1147. Price, $6.00. Philadelphia: F. A. Davis Company. 1901.

Four new articles appear in this edition: on the galvanic current, on the electrical treatment of aneurysm, on the Roentgen rays, and on the treatment of cancer by cataphoresis of mercury. The book is a compilation of articles on electricity by various men, rather than a systematic work, and consequently contains much that is mere repetition. Many of the chapters are out of date.

Married.

BENSON S. ROBERTS, M.D., to Miss Janie S. Ing., both of Baltimore, October 29.

THOMAS MOORE, M.D., to Miss Evelyn Scott, M.D., both of Detroit, Mich., October 30.

EUGENE E. MARTIN, M.D., to Miss Mae C. Stemler, both of Buffalo, N. Y., October 30.

R. WOODS OGILVIE, M.D., to Miss Jimmie Lester, both of Princeton, Ky., November 6.

A. B. AUSTIN, M.D., to Miss Mary Emma Shaw, both of Long Beach, Cal., October 24.

BENJAMIN L. HUME, M.D., to Miss Harriet Randolph Jones, both of Petersburg, Va., October 30.

CHAUNCY M. BENEDICT, M.D., to Miss Claire Clawson, both of Salt Lake City, Utah, October 29.

WILLIS SANFORD HOBSON, M.D., to Miss Florence Marsh Lower, both of Cleveland, October 30.

JACOB A. STOUT, M.D., Columbus, Ohio, to Miss Carrie Bidleman, Circleville, Ohio, October 22.

HENRY SAMUEL ZIMMERMAN, M.D., Chicago, to Miss Pearl Mae Whitman, Cameron, Ill., October 30.

JOSEPH D. DAVIDSON, M.D., Fresno, Cal., to Mrs. Louise Peden Rose, Nashville, Tenn., November 12.

GEORGE H. BRANNON, M.D., Mayor of Manhattan, Ill., to Miss Margaret Moran, Chicago, October 31.

AUGUSTUS RALPH REDER, M.D., assistant medical director of the Burlington road, Chicago, to Miss Susie Alice Pierce, Aurora, Ill., October 30.

Deaths and Obituaries.

Arthur E. Mink, M.D., Syracuse (N. Y.) University College of Medicine, 1887, professor of nervous and mental diseases and of general medicine in the College of Physicians and Surgeons, St. Louis, neurologist to the City Hospital and a member of the St. Louis Medical Society and the American Medico-Psychological Association, died after a prolonged illness from hepatitis, at his home in St. Louis, October 31, aged 37.

Melville D. Peck, M.D., Columbian University, Washington, D. C., 1869, died at his residence in Washington, D. C., October 25, from heart disease, aged 59. He was born in Solon, N. Y., and enlisted in the Tenth N. Y. Cavalry and at the close of the Civil war began the study of medicine. After practicing in Cortland, N. Y., he became a clerk in the U. S. Patent Office and finally in the Pension Bureau, where he remained until his death.

James Lytton Flynn, M.D., Kentucky School of Medicine, Louisville, 1865, was found dead in his room at Milwaukee, November 2, aged 68. He was a veteran of the Mexican war, a surgeon in the Union Army during the Civil war, a practitioner in Louisville for a time, but since 1871 had been a resident of Milwaukee. Apoplexy was the cause of death.

William A. Dinwiddie, M.D., Jefferson Medical College, Philadelphia, 1859, assistant surgeon during the Civil war, and thereafter a lieutenant of cavalry in the U. S. Army, died after a long illness, due to injuries received in the line of duty, at Palmyra, Wis., November 4, aged 62. The remains were taken to Cedar Falls, Iowa, for interment.

Charles H. Orton, M.D., Trinity Medical College, Toronto, 1848, a resident of Milwaukee from 1849 to 1888, where he was city and county physician for twelve years, for many years a member of the common council and its president, and who had lived in Chicago since 1888, died at his home in that city, November 8, from senile debility, aged 84.

Reuben D. Mussey, M.D., Miami Medical College, Cincinnati, 1871, a prominent physician of Cincinnati and for the past twenty-five years surgeon and chief surgeon of the Cincinnati, Hamilton and Dayton Railroad, died November 4, at his residence in Glendale, from blood poisoning, after a protracted illness.

Edward E. Riggs, M.D., Jefferson Medical College, Philadelphia, 1886, a prominent physician of Pittsburg, resident physician at Mercy Hospital and a member of the South Side Medical Society, died at the home of his father, Dr. Isaac W. Riggs, in Pittsburg, November 2, from consumption, aged 37.

John W. Allen, M.D., Bellevue Hospital Medical College, New York, 1881, a member of the Louisiana State Medical Society and a prominent practitioner of Shreveport, La., died at his home in that city October 27, from nervous prostration, after an illness of two years, aged 43.

John T. Laning, M.D., Pennsylvania Medical College, Philadelphia, 1863, a surgeon in the New Jersey Volunteers during the Civil war, and thereafter a practitioner in Wash-

ington, D. C., was found dead in a churchyard in Hopewell, N. J., his home, October 31, aged 70.

D. B. Allen, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1861, surgeon of the First Iowa Cavalry and Thirteenth Iowa Infantry during the Civil war, and an esteemed practitioner of West Liberty, Ohio, died at his home in that city, November 3, aged 78.

Oscar E. Yates, M.D., twice mayor of Holland, Mich., a prominent physician of over 30 years' practice, a member of the Michigan State Medical Society and of the American Medical Association, died at his home in Holland, October 27, from pneumonia.

Edward G. White, M.D., Starling Medical College, Columbus, Ohio, 1854, a surgeon in the United States Army during the Civil war, and a resident of La Grange, Ind., for nearly half a century, died at his home, October 27, from apoplexy, aged 71.

Joseph N. Norcross, M.D., Jefferson Medical College, Philadelphia, 1872, one of the best-known and most respected physicians of Old Town, Maine, died at his farm at Otter Stream, near Milford, after an illness of two years, November 9, aged 50 years.

William F. Harris, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1885, state senator for his district and a successful and popular practitioner of Hancock County, Ill., died at his home in Ferris from typhoid fever, November 3, aged 37.

Asbury C. Helm, M.D., Bellevue Hospital Medical College, New York, 1871, died October 23 from the effects of an overdose of morphin, at his residence in Sawyer's Bar, a mining camp in Siskigou County, Cal., aged 56.

Edwin Windele, M.D., M.R.C.S. Edin., 1876, died at his residence in San Francisco, November 3, after a short illness, aged 52. He had been a resident of California since 1879, and of San Francisco since 1884.

James Barnes, M.D., Jefferson Medical College, Philadelphia, 1825, a life-long resident of Beaver County, Pa., died at his home in New Brighton, October 27, after many years of illness, aged 82.

John C. Orr, M.D., University of Pennsylvania, 1895, captain and assistant surgeon of Volunteers, of Chambersburg, Pa., died September 12, from dysentery, at Mindanao, Philippine Islands, aged 31.

Eugene D. Whitney, M.D., College of Physicians and Surgeons, Chicago, 1898, health officer of Painesville, Ohio, died at his home in that village from typhoid fever, November 4, aged 32.

George Francis Swan, M.D., University and Bellevue, New York, 1899, a member of the New York State Medical Association, died at his home in Highbridge, New York City, November 5.

Charles M. Spalter, M.D., Harvard Medical School, Boston, 1900, and a former interne in the Woman's Hospital, New York City, was accidentally shot and instantly killed, November 8, aged 26.

Edward G. Watson, M.D., Rush Medical College, Chicago, 1884, a prominent physician of Friend, Neb., and fusion state senator in 1897, died at his home, October 31, from typhoid fever.

James F. Morris, M.D., Memphis (Tenn.) Hospital Medical College, 1884, died at Crowley, La., November 4, from cerebral hemorrhage, after a short illness, aged 45.

John W. Littleton, M.D., College of Physicians and Surgeons, Baltimore, 1885, who had practiced in Salisbury and Albemarle, died in Greensboro, N. C., November 2.

Orrin N. Moon, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1881, died at his home in Howell, Mich., November 3, from kidney disease.

William W. Blackman, M.D., New York University, 1848, one of the oldest and best-known practitioners of Iowa, died at Osage, November 5.

William J. Gillett, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1868, died at Parsons, Kan., October 30, aged about 60.

C. Purcell Woodward, M.D., Baltimore University School of Medicine, 1892, of New Egypt, N. J., died at Toms River, November 4.

James Gun, M.D., McGill University, Montreal, 1861, for forty years a practitioner at Durham, Ontario, died October 23.

Thomas P. Crittenden, M.D., University of Nashville, Tenn., 1864, died at his home in Nashville, November 2.

Miscellany.

Jules Bizzozero.

Italy has lost this year one of her most prominent medical scientists, the distinguished professor of general pathology at the University of Turin. Jules Bizzozero was born at Varesa, in 1846. He obtained his general education at Milan and graduated in medicine at Padua when 20 years of age. He became a military surgeon during the War of Independence immediately after, but devoted the remainder of his life to scientific work in medicine. He studied with the microscopist, von Frey, in Zürich, and afterwards with Virchow, in Berlin. At the age of 27 he was made professor of pathology in the University of Turin.

As a student at Padua, he began work in medicine at a time when the influence of the German spirit was first being felt in Italy. At the early age of 16 years, Bizzozero published a paper dealing with the structure of bones in batrachians, and at the age of 18, another concerning the processes of epithelial cells, in which he asserted that the so-called prickles were not canals, but connections between the cells, leaving spaces between them for the passage of nutritive juice. Among his earlier studies, too, were those which resulted in the demonstration of connective tissue cells with their prolongations in the juice canaliculi of von Recklinghausen. Bizzozero was among the first to study the histology of experimental tuberculosis and contrast the changes therein with those in chronic inflammation. In 1865 he observed the contractility of the cells of the bone marrow, and in 1869, at the age of 23, published his complete work on the bone marrow, including a description of the course of the blood vessels and an explanation of the slowness of the circulation. He observed the division of the nucleated red blood corpuscles, described the globuliferous cells which occur in the marrow and interpreted them properly and distinguished the myeloplaxes of Robin from the cells with large budding nuclei, now known as megalocaryocytes. He also studied the changes which occur in the bone marrow in various diseases. He was one of the first to observe and study cell inclusions—the pioneer work in what later developed as the doctrine of phagocytosis.

With Bozzolo, Bizzozero published a monograph on tumors of the dura mater; with Manfredi, another on the structure of molluscum contagiosum; with Salvioli, another on serous membranes, especially on the lymph vessels of the diaphragmatic peritoneum.

He invented the chromocytometer in 1879, and with it studied the variations in the blood after hemorrhages, and the effects of peritoneal transfusion of defibrinated blood. This instrument is still largely used in Italy, and is for that country what the instruments of Gowers and of von Fleischl are to us. Bizzozero was one of the first to study the return of the hemopoietic function of the spleen in the adult after repeated hemorrhages. With Torre he studied the origin of the red blood corpuscles in birds and proved that they come only from vessels in the bone marrow. He demonstrated the indirect division of the red blood corpuscles in lower vertebrates and in embryo mammals. In 1882 appeared his complete work upon the blood platelets, or, as he called them, the "piastrine." He maintained that they pre-existed in the blood of mammals, combated Hayem's idea that they are an early stage of the

red corpuscles, and proved their great significance in relation to the formation of white thrombi.

Bizzozero's "Manual of Clinical Microscopy" has been in great vogue on the continent. It appeared first in 1885 and has passed through several editions, the fifth having been published during this year; it has been translated into a number of foreign languages.

With his pupils, he was busily engaged from 1887 to 1893 in the study of the physiological regeneration of glandular elements and upon the influence of the nervous system, of the state of nutrition and of temperature upon these processes. It was he who found that it is in the depths of the glands of Lieberkuehn and of the gastric glands that karyokinetic regeneration of the gastroenteric epithelium takes place. The sum of his results in this field are embodied in his well-known address, made before the International Medical Congress at Rome, in 1893. At about this period, Bizzozero began to suffer from a choroiditis, which prevented further work with the microscope. He then turned his attention to questions of sanitary legislation and did much to educate the Italians regarding hygienic problems, particularly of vaccination, tuberculosis and malaria.

He numbered among his students many of the more important of our modern Italian investigators, including Golgi, Manfredi, Bassini, Foà, Tizzoni, Salvioli and Vassale. Foà, who has written in the *Archives Italiennes de Biologie* the appreciative notice of Bizzozero's life, from which we have derived the above data, states that he is to be regarded as a most remarkable man, to whom Italy owes a large part of the renewal of scientific interest in the medical schools of that country, and the impulse given to modern sanitary reform. Bizzozero was a tall man, of delicate constitution, but of noble countenance. A victim to neuralgia, he maintained in spite of it a cheerful temperament and a remarkable capacity for work. Though a senator at Rome, he was never in the full sense of the word a political man. At all times, and especially in his later life, he was deeply interested in sanitary laws of a social character.

Smallpox in Kentucky.

Of the one hundred and nineteen counties in Kentucky all but nine—Clinton, Cumberland, Edmonson, Estill, Gallatin, Harlan, LaRue, Owsley and Trigg, all remote from the main lines of travel—have had more or less experience with smallpox during the present epidemic, covering a period of nearly four years. Detailed reports from 108 of the afflicted counties and from every municipality in the state have been received by the State Board of Health. A total of 394 distinct outbreaks are reported, 85 of these being fresh importations from other states. In all 11,269 cases are reported, with 184 deaths, a mortality of 1.63 per cent. Special hospitals were erected in 63 counties and municipalities, but probably a majority of cases outside of the large cities and towns were isolated and treated in their homes. Reports are made of 392,280 persons vaccinated during the epidemic, and of 408,825 found protected by one or more previous vaccinations, out of a total population of 2,147,174, leaving 1,335,039, or a little more than 62 per cent. unvaccinated; 340,000, or over 40 per cent. of those vaccinated, are residents of the larger cities and towns, 175,000 of the City of Louisville. The actual cash expended from county and municipal treasuries on account of smallpox was $308,271, to say nothing of the expense to individuals. The reported loss from interference with business was $734,000. This does not include the great loss to transportation companies from interference with travel and commerce. This latter item is only an aggregate of estimates, many boards not reporting upon this point, and is only given for what it is worth.

These are the bare, naked figures in regard to the most expensive and widespread epidemic from which our state has ever suffered, and covers an experience which might have been easily avoided had heed been given to the united voice of the medical profession and the iterated and reiterated warnings of state, city and county health officials urging universal vaccination. Our people had had little experience with smallpox since the Civil war, and a generation had grown up not only unprotected by, but indifferent to, vaccination. A generation of physicians had come on also, most of whom had never seen a case of smallpox. These conditions account for the frequent errors in diagnosis, and this in turn for the wide prevalence of the disease. The origin of the present epidemic is now pretty well understood. The disease was brought from Honduras to Mobile in the winter of 1896-7, gradually spread up through the mining regions of Alabama and Tennessee, the first case reaching us at Middlesboro from Birmingham early in December, 1897, in the person of a negro miner. The case was mild, no physician was called, and numerous cases and many exposures had occurred before the character of the disease was recognized and reported. It was stamped out after 281 cases and 4 deaths, the city being in rigid quarantine until it was done. The next importations were from Knoxville to Jellico and Richmond, and at both places many cases and exposures occurred before the disease was diagnosed and reported, but both outbreaks were stamped out in the face of much difficulty. From this time on importations were frequent and into widely separated sections of the state. The funds of this board were soon exhausted and we were unable to send our inspectors to the assistance of the local boards except where the local fiscal authorities would meet the expense. But leaflets and circulars of warning were scattered broadcast and multiplied a thousand fold by the generosity of the newspapers.

In the spring of 1900 the General Assembly increased the annual appropriation of the board to $5000, and, when this became available in June, we were again able to take the field against the disease in earnest. Many county and municipal boards of health had been able to do ideal work in the meantime with funds furnished by their respective fiscal authorities, confining the disease to first cases or families in nearly every instance. This was the desire of the local boards everywhere, but as a rule they were hampered and thwarted by the parsimony and shortsighted economy of the local purse-bearers, and too often the disease spread from community to community practically unhindered. For this reason our work was very difficult for some months, but some counties and towns were persuaded, some threatened, and a few put under strict non-intercourse quarantine. At last the headway was apparent and by October 1 of this year not a case existed in the state. Since that time importations have been made into three widely separated counties, and with 62 per cent. of our population not only unvaccinated but ignorant and negligent upon the subject, the whole work may have to be done over at any time.

Our management of the disease was very simple. The first case or cases, and all subsequent cases were rigidly isolated, in a hospital where possible; all exposed persons were searched out, vaccinated, and kept under observation, and vaccination was urged on all in the contiguous territory. In many country districts we were forced to adapt these methods to local conditions. One of the greatest of our difficulties was in securing satisfactory and reliable vaccine virus. In my experience, infected and bad arms followed the use of the glycerinated lymph much more frequently than of the dry points, and this accounts for much of the opposition we have had to vaccination.—Abstract from forthcoming Report of State Board of Health, by Dr. J. N. McCormack, Secretary.

The Passing of Sectarianism in Medicine.—We are optimistic enough to believe that the conditions outlined in the closing paragraph of Dr. Reed's eloquent Presidential Address, delivered at the St. Paul meeting of the American Medical Association, will be brought to pass before another generation has come and gone. There is a very considerable number of able and scholarly practitioners of medicine who are at the present time barred from the privilege of professional association with those who form the great body of scientific practitioners because they were misguided and ill-advised when they began the study of medicine and the sectarian atmosphere with which they were then surrounded has clung to them ever since. Some voluntarily cling to the name which they have assumed, not because they believe in any of the absurd theories which

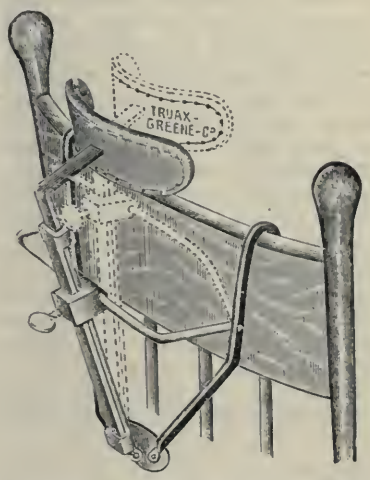
were held when the school to which they belong was born, but simply because there is money in it. The majority, we believe, cling to the name because under the present conditions they see no way of escape, and if they should openly renounce the creed which they have long since ceased to believe, they would find themselves adrift with no port in sight. . . . We believe that it will be generally admitted that many of those who practice medicine under some sectarian name are men of good education and are perfectly competent to take care of their patients, and indeed that they treat their patients exactly as other physicians do, and are perfectly familiar with the modern principles of pathology, diagnosis and treatment. These men, or at least a large proportion of them, would be glad to drop their exclusive name and join the ranks of scientific practitioners of medicine if an opportunity to do so were offered them. A great deal of opposition would have to be overcome, especially among the older men, many of whom would find it impossible to give up the prejudices of a lifetime, but the complete organization of the whole profession which would ultimately result from the disappearance of all the false systems, which even although they exist in name only, are still a very real barrier to the progress of scientific medicine, would accomplish such a vast amount of good that we hope to live to see it brought to pass.—*St. Paul Medical Journal.*

New Instruments.

SOME NEW INSTRUMENTS.

FRANK ALLPORT, M.D.
CHICAGO.

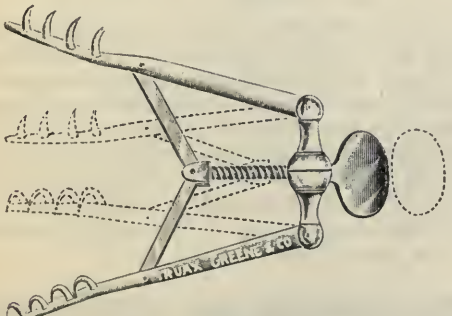
An annoying feature of eye and ear work in a general hospital is the lack of concentration of instruments, drugs, appliances, etc., necessitating many delays incident to nurses or internes going from ward to ward in search of needed articles. I have endeavored to obviate this difficulty by designing an eye and ear case for hospital work which will contain practically all that is essential for ordinary service. The case is constructed of nickel-plated copper.



It has a strong handle, making it easy of transportation from ward to ward. It has a cover for protecting it from dirt. The top compartment is divided into large spaces for holding bulky objects, such as head mirrors, insufflators, tuning forks, etc., and small places for holding solutions, ointments, cotton, etc. It has a large drawer also for holding bulky objects, and a small drawer for holding knives, scissors, forceps, etc. In my own hospital service I find it a great time-saver, and most convenient, and I trust it may prove so to others.

An instrument which I have found useful is a simple gauze-packer, originally intended for mastoid work, but which may find a use elsewhere. The end of the packer is conical in shape with a flat base, thus presenting no tendency for with-

drawal of the gauze as the instrument is withdrawn, nor perforation of the gauze by the point of the instrument, as the wound is packed.



I desire to call attention to a head-rest which I have used in my office for nearly twenty years. It is especially useful for the external examination and treatment of eyes. It may also be used in small operations where the patient may maintain a sitting posture, and I have frequently used it in hospitals and homes, for cataract and iridectomy operations, etc. It can be used upon the back of any plain wooden chair, and when thus placed makes an exceedingly good operating chair. The head can be raised or lowered by a simple thumb-screw on the back of the frame.

I have referred so many times in the past to my mastoid retractors that I am almost ashamed to speak again at the present time, my excuse being their frequent imperfect manufacture, and misuse. I claim complete priority in the suggestion of self-retaining mastoid retractors, notwithstanding which fact several surgeons have devised modifications of my retractors without the courtesy of a recognition of my original instrument. I have yet to see a retractor the equal of my first instrument in simplicity, practicability and efficiency. I am, therefore, anxious that it should be manufactured and used correctly.

When small openings and drills were used in opening the mastoid bone, one retractor was sufficient, but now that large openings and chisels are deemed the best surgery, I use two instruments, one in each end of the wound, as shown in the picture.

When thus used the retractors open the wound to its fullest capacity, and give the operator an ample field for his work, without an extra pair of hands around the head, which is, of course, necessary in using hand retractors. The teeth on the arms of the retractor should be placed well under the periosteum, and the arms then dilated as widely as possible, using considerable force to thus separate the sides of the wound. Such force necessitates a strong and substantial instrument, and this point is one frequently overlooked by manufacturers who aim to produce a pretty and delicate instrument, rather than one substantial and forceful. The forcible dilatation of the wound not only gives a fine unobstructed and permanent view of the field of operation, but also entirely does away with any material hemorrhage from the soft, flap tissue. I never use artery forceps in a mastoid operation, and it is certainly most desirable to dispense with them if possible. But in order to do this, the retractors must be widely and forcibly separated. Some manufacturers defeat this end by constructing the instrument in such a way that the screw pin is so short as to render a wide dilatation of the blades impossible, thus rendering the instrument practically useless. Other manufacturers accomplish the same undesirable result by making the screw handle round or square, whereas it should be flat, to enable the operator to secure a firm hold, and use all desirable force in turning the screw-head and thereby separating the blades. The distance between the extreme ends of the blades when expanded should be at least two and one-half inches.

It is hoped that manufacturers desiring to make the retractors will heed the above directions, and make them accordingly. It would seem as if a surgeon designing instruments should at least have the courtesy accorded him of having his instruments made according to his specific instructions. I recently went into two Chicago instrument houses, and in the first one found three mastoid retractors of different designs, being sold under my name. They did not bear the slightest resemblance to my retractors, except that they had teeth and spreading arms; one of them was absolutely grotesque in its appearance. At another store they showed me some retractors bearing my name, in which the arms would not spread much over one inch, which of course made the instrument absolutely useless. Such circumstances naturally make surgeons reflect whether it should be considered unprofessional to hold a patent on an instrument. As it is now, the moment he publishes an instrument all manufacturers have a right to make it, and before long the instrument on the market bearing the inventor's name may be so far removed from his original idea as to make him ashamed that he ever gave it to the profession. There certainly should be some way of allowing the surgeon to control the manufacture of his own instrument. It may not be well for him to benefit pecuniarily by its sale (although I believe this to be a subject capable of double-sided argument), but he should at least be able to dictate who should participate in the manufacture of his own devices, and to insist that he be given the opportunity of inspecting all of his own instruments should he care to claim this privilege.

My retractors are usually well made by Tieman & Myrowitz, of New York; Truax, Greene & Co., and Chambers, Inskeep & Co., of Chicago.

92 State street.

Societies.

COMING MEETINGS.

Tri-State Medical Association of Mississippi, Arkansas and Tennessee. Memphis, Tenn., Nov. 19-21, 1901.

Indian Territory Medical Association, Muskogee, Dec. 3-4, 1901.

Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

St. Louis Academy of Medicine.—At its annual meeting, November 5, the Academy elected the following officers: Dr. Augustus C. Bernays, president; Dr. J. William Williamson, vice-president; Dr. Alfred Roulet, secretary, and Dr. G. Howard Thompson, treasurer.

Little Rock (Ark.) Medical Society.—At the annual meeting of this Society held November 4, Dr. William A. Snodgrass was elected president; Dr. Strodder U. King, vice-president; Dr. Charles C. Stephenson, secretary, and Dr. Rezin W. Lindsey, treasurer. The annual banquet will be given by the president November 18.

Detroit Physicians' Association.—At the meeting of this Association at the Cadillac, October 25, the finance committee reported that in the past 10 months about $15,500 has been collected and although a deficit of $450 still existed, due to the small amount of business during the first months, it was decided to continue the system six months longer.

Dodge County (Neb.) Medical Association.—A number of physicians of Dodge County met at Fremont, Neb., October 31, and organized this Association, with Dr. Leander B. Smith, Fremont, as president; Drs. Robert C. McDonald, Fremont, and J. M. Doan, North Bend, vice-presidents; Dr. A. P. Overgard, Fremont, secretary, and Dr. William J. Davies, Fremont, treasurer.

Somerset County (Pa.) Medical Association.—At its recent annual session held at Rockwood, the following officers were elected: Dr. Harmar D. Moore, New Lexington, president; Dr. W. H. Gardner, Rockwood, vice-president; Dr. H. Clay McKinley, Meyersdale, secretary; Dr. Asa F. Speicher, Elklick, corresponding secretary, and Dr. Walter S. Mountain, Confluence, treasurer.

Aesculapian Society of the Wabash Valley.—The fifty-fifth annual meeting of this Society was held at Paris, Ill., October 31, with 75 members in attendance. Dr. Charles B. Fry, Mattoon, Ill., was elected president; Dr. Edgar L. Larkins, Terre Haute, Ind., vice-president, and Dr. Harry McKennan, Paris, Ill., secretary and treasurer. The Society adjourned to meet in Mattoon, Ill., in May, 1902.

West Texas Medical Association.—The twenty-fifth annual meeting of this Association was held at San Antonio, October 31. Resolutions of regret and sympathy on the death of Dr. McPherson Barnitz were passed and the following officers elected: Dr. William E. Luter, San Antonio, president; Drs. Alfred G. Heancy, Corpus Christi, and Edward B. Jackson, San Antonio, vice-presidents, and Dr. W. B. Russ, San Antonio, secretary and treasurer.

Rock Island County (Ill.) Medical Society.—More than 20 physicians of Rock Island, Moline, and Rock Island County, met at the Harper House, Rock Island, October 31, and formed a county organization in accordance with the plan formulated by the American Medical Association. Dr. Carl Bernhardi, Rock Island, was elected president; Dr. Lewis D. Dunn, Moline, vice-president; Dr. John G. Swensson, Moline, secretary, and Dr. Warner L. Eddy, Milan, treasurer.

Central New York Alumni Association of the Albany Medical College.—At the annual meeting of this Association, held at Fulton, N. Y., October 31, the following officers were elected: Dr. Wilmer C. Kellogg, Syracuse, president; Drs. Richard F. Stevens, Lysander, Charles J. Bacon, Fulton, G. Griffin Lewis, Syracuse, William C. Fawdrey, Lorraine, Charles B. Tefft, Utica, and Charles Bernstein, Rome, vice-presidents; Dr. Frederic H. Brewer, Utica, secretary, and Dr. Merritt B. Fairchild, Syracuse, treasurer. The next meeting will be held at Syracuse in September, 1902.

Ingham County (Mich.) Medical Association.—The physicians of Ingham County met at Lansing, October 29, and perfected the organization of a society, whose work will be to ascertain the legal status of doctors in the county. Dr. Frank E. Thomas, Mason, was elected chairman, and Dr. D.

M. Nottingham, Lansing, secretary and treasurer. It was resolved to ask every doctor in the county to pay an assessment of $1 each into a fund to employ legal counsel to fight the board of supervisors' action in cutting down their claims for treating typhoid fever and consumption.

NEW YORK STATE MEDICAL ASSOCIATION.

Eighteenth Annual Meeting, held in New York City, Oct. 21-24.

(Continued from page 1267.)

THIRD DAY.—WEDNESDAY, OCTOBER 23.

Arteriosclerosis; Importance, Definition, Etiology and Symptomatology.

DR. CHARLES E. NAMMACK, New York City, opened the symposium on arteriosclerosis with this paper. He said that by arteriosclerosis was meant a hyaline degeneration of the structural elements of the vessel wall with hyperplasia and subsequent contraction of the caliber of the vessel. The effect was first an impairment of contractility, and later a weakening of elasticity and osmosis, with consequent interference with metabolism. There could be no doubt that individuals were born differing in the thickness of the arterial walls as much as in the size and development of other parts of the body. Statistics showed that in Greater New York the death rate among physicians, whose worries make them an easy prey to arteriosclerosis, was only exceeded by those of saloon-keepers, who are intemperate, and by butchers, and the most underpaid factory operators. Thirty-five per cent. of these medical men died from Bright's disease, apoplexy and heart disease—the threefold sequelæ of arteriosclerosis. In connection with the treatment it was well to remember that out-door exercise dilates arteries better than do the iodids.

Cardiac Manifestations of Arteriosclerosis.

DR. DE LANCEY ROCHESTER, Buffalo, said that the treatment of the underlying arteriosclerosis was the all-important thing in connection with such disorders of the heart. By reason of its action on the heart and arterioles digitalis is dangerous, and should only be used as an emergency drug, and then cautiously and only for a very short time. He much preferred to use a reliable fluid extract of cactus. In the treatment of an attack he made use of amyl nitrite by inhalation, nitroglycerin by hypodermic injection, with sometimes morphin and atropin.

Management and Therapeutics of Arteriosclerosis.

DR. EGBERT LEFEVRE, New York City, said that it was often necessary to make use of the nitrites, but their effect did not last at most more than two hours; moreover, if given too freely they tended to hasten degeneration. The iodids have the power of steadying the circulation and of lowering arterial tension without reducing the force of the systole of the heart. The syrup of hydriodic acid should be given three times a day in doses ranging from one to four drams. When the hypertrophy of the heart no longer fully compensated for the obstruction in the arteries it would be found desirable to give every night from two to four minims of the tincture, or half a grain of the leaves of digitalis.

DR. STURTEVANT called attention to the great variations in the strength of the fluid extracts of cactus on the market, making the dosage vary from two to fifteen minims.

DR. JAMES J. WALSH, New York, spoke of the important rôle played by heredity, and the useful hint thus afforded the medical adviser in helping predisposed persons to select the most suitable vocation in life.

DR. CHARLES G. STOCKTON, Buffalo, remarked that in these cases gastralgia was often such a prominent symptom as to overshadow the disorder of the heart.

Blood Examination from the Standpoint of the General Practitioner.

DR. FRANK W. HIGGINS, Cortland, said that the specific gravity of the blood could be readily ascertained with no other instrument than a urinometer. Chloroform and benzine are mixed in such proportions that the drop of blood neither sinks nor floats, and then the specific gravity is taken with the urinometer. The specific gravity varies to correspond with the hemoglobin. In the determination of the percentage of hemoglobin there is an error of 5 per cent. arising from differences in using the scale of colors. A leucocytosis of 12,000 to 50,000 meant infection, most commonly with the formation of pus. This sign was often useful in differentiating between appendicitis and typhoid, and in diagnosticating a pneumonia having masked physical signs. Another important point for the general practitioner to remember was, that a diminution in the red blood corpuscles was the only rational basis for the use of either iron or arsenic. The paper closed with some practical remarks on the technique and results of microscopic examination of stained specimens of blood.

DR. RICHARD C. CABOT, Boston, said that the determination of the hemoglobin could now be readily undertaken at the bedside, thanks to the invention of Tallqvist's hemoglobinometer. This is nothing more than a scale of color and a pad of special bibulous paper bound in the form of a small book that can be carried in the pocket. It is only necessary to place a drop of blood on a leaf of this paper, and then compare the color so produced with those found on the color scale to enable to read off the percentage of hemoglobin within 10 per cent. Another good point about this device is that it only costs $1.25.

Conservative Surgery for Tuberculosis of the Lymphatic Glands of the Neck.

DR. PARKER SYMS, New York City, presented this paper. He was of the opinion that the very radical method of operating on these glands was unnecessary in the majority of cases, and was objectionable because it does not offer a sure and permanent cure and because it increases rather than diminishes the danger of systemic infection. Where the glands were not broken-down they should be anointed with a 10 per cent. ichthyol ointment, but where they were broken-down, they should be incised and drained before rupture takes place. They should then be treated with a 10 per cent. emulsion of iodoform and glycerin, and if this were persisted in for a sufficient length of time the result would usually be very satisfactory both to the patient and the surgeon.

President's Address.

DR. JOHN A. WYETH, New York City, delivered this address, on "Comments on Some New Surgical Methods." Speaking of intraspinal cocainization he gave it as his opinion that the credit for introducing this new method of inducing anesthesia belonged to Dr. August Bier rather than to Dr. J. Leonard Corning. The method was certainly useful in certain cases, and he would not hesitate to employ it in persons who objected strongly to the usual methods of anesthetization. Dr. Wyeth next considered a method of obliterating blood vessels by injection. This is original with him, and was based on some experiments on dogs in which he had succeeded by the injection of boiling water in obliterating the external carotid artery down to its terminal branches. The method, which had been suggested by witnessing the results of Dr. Dawbarn's method of cutting off the nutrition of neoplasms by ligation of their main artery, had been tried on the human subject in one case, and with a gratifying result. The remainder of his address was devoted to a brief consideration of the promising operation of prostatectomy and of the proposed treatment of cancer of the breast by removal of the ovaries.

Iodophilia.

DR. RICHARD C. CABOT, Boston, opened a discussion on the value of bacteriological and pathological research in diagnosis, prognosis and treatment, by this paper on iodophilia. He said that the term merely referred to a long-known reaction of the polynuclear leucocytes to iodin. The reagent employed is composed of one part of iodin, three parts of iodid of potassium, 100 parts of water and enough gum acacia to make a thick syrup. It was a fairly stable solution, and would not require renewal for several months. The reaction consisted in the production of a more or less brownish coloration, chiefly in-

tracellular, of the polynuclear leucocytes. Its significance could not be stated with accuracy, but it could be said positively that when it was present the individual was sick. It would be obtained in cases of asthma, pneumonia, abscess formation, well-marked anemia, either primary or secondary, and, in general, in toxemia.

Laboratory Differential Diagnosis in Surgery.

DR. SIMON FLEXNER, Philadelphia, contributed to the discussion a general review of the results of laboratory research, speaking specifically of the Widal reaction, leucocytosis, examination for malarial parasites in the blood, etc.

Modifications in Methods of Operative Surgery Resulting from Laboratory Research.

DR. JOSEPH D. BRYANT, New York City, closed this special discussion by an interesting historical account of certain surgical cases occurring in Bellevue Hospital thirty years ago, and contrasting the treatment then in vogue with modern methods, the result of much laboratory investigation.

The Pneumatic Cabinet in Treatment of Diseases of the Heart.

DR. CHARLES E. QUIMBY, New York City, gave in this paper the results of a long personal experience with the cabinet in this class of affections. He is one of the few who still have faith in this apparatus, and certainly he adduced a mass of clinical evidence in support of that faith. He defined pneumatic differentiation as a difference of atmospheric pressure upon the lungs and upon the cutaneous surface, and pointed out that such differentiation, by lowering vascular tension and augmenting the flow of blood, improves general nutrition.

Gunshot Wounds of the Hip Joint by Reduced Caliber Projectiles.

MAJOR LOUIS A. LA GARDE, Washington, D. C., presented specimens and skiagrams illustrative of some of the effects of modern small-caliber bullets, and pointed out the humane character of these modern projectiles when fired at the usual range employed on the field of battle. A striking statement was that since the Civil war the mortality from gunshot wounds of the knee had been reduced over 78 per cent.

DR. G. N. JACK, Depew, explained in a paper on "Asthma of Blood Origin, and not Nerve or Reflex," his theory of the blood origin of asthma. His idea is that asthma arises from an inability of the blood to carry the requisite quantity of oxygen.

Acne.

DR. EDMUND L. COCKS, New York City, speaking of acne vulgaris, said that about 75 per cent. of the cases are met with before the age of 18, and that, in general, it may be looked upon as an indication of impaired digestion and circulation. If proper treatment were not instituted sufficiently early there was apt to result a good deal of disfigurement. The treatment consisted in a general attention to hygiene, the exclusion from the dietary of pastry, hot bread, sweets, fried meats, potatoes and alcohol. After curetting the lesions a soothing lotion should be applied, and the parts should be sponged with hot water at night.

DR. FRANK D REESE, Cortland, took issue with the author regarding the difficulty of treating acne, and claimed that by proper attention to the habits of life, and insisting that the patient make free use of the nail-brush and of tincture of green soap, there should be no great difficulty in curing these cases.

FOURTH DAY.—THURSDAY, OCTOBER 24.

Surgical Malposition of the Gall-Bladder.

DR. E. D. FERGUSON, Troy, reported three cases to illustrate a fact not generally mentioned in the text-books of either surgery or anatomy, i. e., that the position of the gall-bladder is variable. In the first case, it was located behind the posterior border of the liver; in the second, it was behind the peritoneum at the posterior edge of the inferior surface of the liver, and in the third case extended from the lower surface and posterior border of the liver downward behind the colon.

Differential Leucocyte Count in Fractures.

DR. WILLIAM G. LE BOUTILLIER, New York City, gave the results of observations on the temperature and blood in a series of fractures. Thus, in 50 consecutive cases of simple fracture the temperature had often been as much as three degrees above the normal. In no instance had the temperature reached the normal before the third day after the injury, and in 25 per cent. of the cases had still been somewhat elevated at the end of two weeks. However, this temperature was not to be taken as an index of the occurrence of infection in compound fractures, for in many instances it had been about the same in both classes of fractures on the second or third day. Sixty-five differential blood counts had been made in 73 cases of simple fracture, and 39 counts in 10 cases of compound fracture. The ordinary leucocyte count had appeared to be a better test of infection than the temperature, though not quite reliable. On the first day there had been about 85 per cent. of polynuclear neutrophiles and less than 15 per cent. of leucocytes, but after the first two days the lymphocytes had increased as the polynuclear neutrophiles had diminished. The differential counts had borne no appreciable relation to the temperature.

Prostatic Obstruction to Urination; Its Remedy by Enucleation of the Diseased Parts.

DR. J. W. S. GOULEY, New York City, discussed in this paper the nature of prostatic enlargement and what had been accomplished by enucleation.

DR. PARKER SYMS, New York City, said that he had been working in the direction of doing the enucleation of the prostate entirely by the perineal route, as he believed that in this way the mortality of the operation could be very materially reduced. As an improvement in the technique he had introduced the use of a special retractor that he had devised. It consists of a rubber bulb attached to a tube like a catheter. The instrument, while collapsed, is introduced into the bladder through an opening in the membranous urethra, and is then distended by injecting into it two ounces of water. The instrument thus serves to hold the bladder in place and draw the prostate towards the wound. He had used it with considerable satisfaction in upwards of a dozen cases. (See THE JOURNAL, Nov. 2, p. 1154.)

DR. EUGENE FULLER, New York City, thought the surgeon should not employ any one surgical procedure to the exclusion of others. For example, where the prostate is very large, enucleation through the perineum would be tedious and rather dangerous to an old man. Again, when the bladder was very atonic it would be much safer to employ a suprapubic opening in order to efficiently cope with hemorrhage.

DR. E. WALLACE LEE, New York City, said that these old men were seldom in condition to stand prostatectomy, yet they could often be relieved by simple suprapubic cystotomy with drainage. Moreover, he had personally witnessed a reduction of the size of the prostate as a result of castration and vasectomy.

Vesical Emergencies; Their Surgical Management.

DR. EUGENE FULLER, New York City, spoke, among other things, of what constituted the best modern practice in the treatment of retention of urine, both from inflammatory obstruction and from prostatic enlargement. He pointed out that the old-fashioned silver prostatic catheter, while an effective instrument, was a very dangerous instrument, and should only be used very carefully and to meet an emergency.

Uterine Prolapse.

DR. FREDERICK HOLME WIGGIN, New York City, said that the proper treatment of uterine prolapse required that an operation be done to obliterate the hernial sac and restore the damaged perineal structures. The prolapsed parts should be reduced, the patient be placed in bed with the foot of the bed raised, the local ulcerations should be made to heal by the use of antiseptic tampons. When this had been accomplished, a laparotomy should be performed and a purse-string suture of

kangaroo tendon inserted through the uterus, about the attachment of the round ligament, and then into the broad ligament in such a way as to fold up this ligament. Such a suture is inserted on each side, and the uterus thus given a new point of attachment near the insertion of the broad ligament at the pelvic brim. After the patient had been confined to bed for a period of four or five weeks, a second operation should be done for the suture of the separated tendons of the perineal muscles. The author said that this operation had yielded him very good results, even in aged women, because of the rapidity with which it could be done and the absence of any great blood-loss.

Typhoid Cholecystitis.

Dr. Charles G. Stockton and Dr. Albert T. Lytle, Buffalo, presented a joint paper on this topic, reporting four cases of cholecystitis which had complicated typhoid fever.

Dr. De Lancey Rochester, Buffalo, who had been the attending physician in one of the cases, commented upon the marked indicanuria that had been present. He said that this had increased as the leucocytosis had increased.

Dr. Allen A. Jones, Buffalo, and Dr. E. D. Ferguson, Troy, emphasized the fact that the pain was essentially due to the cystitis and to the presence of gallstones.

Dr. Thomas F. Reilly, New York City, gave the results of an inquiry that he had set on foot at St. Joseph's Hospital among 100 of the phthisical patients found there, in the following paper: "What Percentage of Gouty and Rheumatic Patients Develops Fatal Pulmonary Phthisis?" Only six of this number had never had an attack of acute articular rheumatism, yet not one of the whole series had suffered from gouty disorders or gave a family history of gout. Loss of sleep had been a prominent causal factor in 45 per cent., but exposure to the weather and alcoholic excesses were responsible for many cases.

Dr. E. D. Ferguson, Troy, reported the case of a "Durham Tube in the Right Bronchus," in which this form of tracheotomy tube, owing to a defect in construction, had been swallowed. By the addition of a collar, he said such accidents could be effectually prevented.

Resection of Cervical Sympathetic in Treatment of Glaucoma.

Dr. Wilbur Marple, New York City, reviewed the literature, and commented upon the meager details that Jonnesco had published regarding his own cases, and especially upon the fact that most of the cases had not been kept under observation a sufficient length of time. The improvement often observed after Jonnesco's operation appeared, in most instances, to be temporary.

Dr. James J. Walsh, New York City, said that he had personal knowledge of some of Jonnesco's work, and could say that in some of the cases of glaucoma of the irritative chronic type, operated upon by Jonnesco three years ago, the great improvement in vision that had followed the operation had continued since that time.

Dr. Alvin A. Hubbell, Buffalo, remarked that this operation was still in an experimental stage, and, in his judgment, promised very little.

Report of Case of Gunshot Wounds of Intestines.

Dr. H. Van Hoevenberg, Kingston, reported this case as an example of what could be accomplished in country practice amid unfavorable surroundings, and with the object of impressing the lesson that it was the surgeon's duty, even under discouraging circumstances, to give his patient the best chance for life. Incidentally the case illustrated the value of morphin in cases of perforating wounds of the bowel.

Dr. R. H. M. Dawbarn, New York City, said that he had long advocated the "morphin splint" in wounds of this class, for, such medication by quieting peristalsis and preventing the surging of waves of liquid feces against the wounds, the injured parts were placed at rest and an opportunity afforded nature to seal them up with fibrinous exudate. He also advocated repairing the rents in the bowel with a continuous suture, as the insertion of the interrupted suture takes from three to five times longer.

Dr. George Tucker Harrison, New York City, pointed out, in a paper on "Indications for Treatment in Uterine Myomata," that the hemorrhages, being often dependent solely upon endometritis, should be first treated by curettage before resorting to more radical operations. It was a rule, to which there were but few exceptions, that uterine myomata undergo retrograde degeneration after the menopause.

Technique and Method of Inserting the Fixation Sutures for Prolapsed Kidney.

Dr. Augustin H. Goelet, New York City, prefers to make the incision along the outer border of the erector spinæ muscle, separate the muscles in the direction of their fibers and strip back the fibrous capsule of the kidney. Two fixation sutures are used, and are inserted upon the lower half of the kidney in such a way that the traction comes at a right-angle to the surface of the kidney. The external wound is closed by aseptic strips of adhesive plaster.

Dr. George M. Edebohls, New York City, said that it was a common error to try to fix the kidney by its lower half only. He anchors by means of four suspension sutures, one over the middle of each pole, the kidney being anchored to the raw quadratus lumborum muscle.

Dr. Howard Lilienthal, New York City, said that the technique employed by the author of the paper was exceedingly simple, but he thought all suture methods would fail if room enough were left to allow of the kidney displacing downward. He, therefore, leaves in a gauze packing for about ten days, so as to secure granulation over a large surface and obliterate this space.

Dr. Willy Meyer, New York City, said that the originator of this gauze-packing method had advocated keeping in the gauze for three weeks and then removing it under anesthesia. Dr. Edebohl's technique seemed to him preferable.

Dr. R. H. M. Dawbarn, New York City, objected to the insertion of sutures because they would cause leakage of urine.

Dr. Goelet replied that he had never observed such leakage.

Dr. J. R. Sturtevant, Theresa, reported "A Case Simulating Glanders." with photographs, that others might judge as to the correctness of the diagnosis, about which he thought there was some doubt.

NEW YORK ACADEMY OF MEDICINE—SECTION OF OTOLOGY.

Stated Meeting, held October 9th, 1901.

Dr. James F. McKernon in the Chair.

Dr. George B. McAuliffe presented a new Eustachian cathe ter and demonstrated its use upon a patient. Instead of the angle being in the end of the curve it was distributed along the curve of the instrument. It was especially suitable in those patients with wide nares. The instrument is passed directly into the tube after traversing the outer part of the floor; as it passes over this the septum shoves the catheter right into the Eustachian tube in the last movement of catheterization.

Extensive Thrombus of Lateral Sinus with Re-Infection Following Chronic Suppurative Otitis with Ligation of the Internal Jugular Vein.

Dr. M. D. Lederman presented F. R., 17 years old, who had been admitted to the hospital with symptoms of a septic nature. He gave a history of having a running ear for ten years, which later improved. One week ago he was struck a blow over the right ear, which caused a bloody discharge for two days. There was tenderness over the mastoid, with a temperature of 100.8 F. and pulse 84. Examination revealed an old suppurative otitis with the membrane almost entirely absorbed, and some pus in the middle ear. Antiseptic douching every three hours with the Leiter coil was carried out for twenty-four hours. The following day there was pain over the side of the head. The ice-coil was discontinued so as not to mask the symptoms, as there was a previous history of irregular suppuration. A distinct chill of severe character was followed by the usual symptoms of a septic involvement of the sinus.

On August 12 the first operation was performed. Not much pus was found in the antrum but considerable granulation tissue was removed. The diseased bone was curetted from around the sinus and the vessel was incised from the knee to the jugular bulb. A septic thrombus was found and the lumen of the sinus was cleansed until a free bleeding showed that the posterior opening was patent. No return flow followed the use of the curette through the lower end of the sinus (the jugular bulb), so the jugular was tied about two inches from the clavicle. No disease of the vein in this region could be detected, so no attempt at resection was made. So soon as the ligature was applied it immediately filled with blood, permitting the belief that a free circulation was being carried out through the tributaries. At the end of two days the dressings were removed; the neck wound was clean but the antrum opening showed some pus. The sinus seemed to be doing nicely. It was thought advisable to cleanse the antrum site and so the curette was employed until a clean return of fluid through the external canal showed that the drainage was good. The temperature remained about 99 until the fifth day when it suddenly rose to 105 F. On August 17 some pus was found in the region of the jugular bulb; around this was found some little pus which did not lead to any pocket. The wound was then dressed daily and it was noticed that the temperature fluctuated, with an occasional chill, indicating sepsis in a severe form. On August 22 a purulent discharge was observed and the patient was again operated upon for the third time, and the external wall of the sinus was removed to near the torcular. The incision was made to the end of the bone wound, through the sinus, and the infected thrombus was curetted away. The wound was then douched with bichlorid and the entire wound dressed. The antrum wound was packed separately. The patient rapidly improved. The infection evidently occurred from the antrum, as a portion of the sinus had been thoroughly cleansed at the first operation.

Symptoms Pointing to the Necessity for Operative Interference in Mastoid Suppurations.

DR. WENDELL C. PHILLIPS said that the most marked symptom appearing during the course of an acute suppuration of the middle ear showing involvement of the mastoid is pain which comes on usually some time after the excruciating pain which precedes suppuration of the middle ear has passed away, and after the discharge from the ruptured or incised drum has been established. This pain is dull, heavy, not definitely localized but diffused over the surface of the temple. With it there is a feeling of fulness, heaviness and pressure over the entire parietal region. The pain may, or may not, be constant. Another prominent symptom is tenderness upon pressure, usually marked at the tip of the mastoid, but is more significant if it is higher up over the mastoid antrum; one's mastoid tip may be tender on pressure even when there is no disease present. Temperature was also considered, but it was not a very important symptom in mastoid involvement. Facial expression was emphasized. This expression was one rather indicative of anxiety, an extremely unhappy expression. The head usually hangs forward and leans towards the healthy side. External periostitis with or without infiltration was also considered as a symptom, although, as a rule, operative interference should be resorted to long before these symptoms appear. When present it is more of a complication than a symptom. The drum membrane should not be overlooked in making a diagnosis of mastoid involvement, especially Shrapnell's membrane, the attic region. When this membrane, together with the posterior superior portion of the wall of the canal, is found to be bulging downward and forward into the canal, a picture is given which constitutes one of the most prominent symptoms of mastoid suppuration. Prolonged tenderness upon pressure over the region of the antrum, together with the bulging described, gives sufficient reason for operative interference, especially so when the pus contains streptococci or staphylococci. Symptoms of other complications he simply referred to, such as rigors, vomiting, vertigo, choked disc, aphasia, paralysis of the extremities, high temperature, facial paralysis, dulled mentality, uneven pupils, the so-called typhoid condition, etc. All of these symptoms indicate that the suppurative process has gone far beyond the mastoid cells into either the lateral sinus, the dura, the cerebrum or the cerebellum. It may be possible to have a non-suppurative involvement of the mastoid cells, a mere congestion, but such a condition is hardly probable.

Free incision of the drum membrane carried well through the attic region into the external canal allowing the escape of pus, will often completely relieve all indications of mastoid involvement. The whole theory of such relief is based upon the importance of free drainage; this, together with blood-letting locally, with the ice-coil or hot poultices, should be abortive in a small percentage of cases. During the early stages of middle ear suppuration, and even after the mastoid symptoms appear, irrigation with hot water is commendable treatment. There is a great tendency to use the ice-coil and hot poultices for too long a time; the ice-coil should not be used longer than 24 or 36 hours; the continued use of poultices he considered almost as bad; in fact, any prolonged attempts at aborting mastoid involvement was to be deprecated. He emphasized the importance of placing the patient in bed and keeping him there until all symptoms had passed away. External operation should be performed in acute suppurative inflammations of the mastoid cells when a permanent remission of symptoms has not been brought about by free drainage through the drum membrane, or by the application of the ice-coil or poultices, or from local blood-letting. When the time has arrived for operating there should be no delay. In cases presenting symptoms of mastoid involvement, if there is present in the pus streptococci, staphylococci, or pneumococci, it was his belief that no amount of palliative treatment will have any effect upon the final result; it is especially in the grip cases that we should not delay operative interference. The method of operating should carry out this one prime factor, namely, that all diseased tissue should be removed. Regarding the Wilde incision, aside from the benefits that results from the local blood-letting, nothing was to be expected from it except the annoyance of having an open wound to contend with in a near-by location. It has been stated that if upon making a Wilde incision the external table seemed to be healthy no attempt should be made to enter the cells; experience did not bear out this statement.

Long delayed suppuration of the middle-ear attended with involvement of the attic and probably the antrum and mastoid cells, may lead to the necessity for external operation in order to overcome the suppurative process. This is especially true in cases of chronic otorrhea, the discharge of which is offensive, and with the establishment of cholesteatomatous masses and carious bone. Only by an external operation in many instances may we hope for permanent relief. That a chronic otorrhea is attended with more or less danger to life will not be denied, and to-day life insurance companies refuse absolutely to accept as risks persons who suffer from a chronic discharge from the ear. An attempt should be made to cure permanently all cases of chronic otorrhea. Local measures, removal of the necrosed ossicles and of other known methods, should be made use of before resorting to external operation.

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.

Regular Meeting, held October 7, 1901.

The Society organized for the season by electing Dr. Wm. Osler president, and Dr. Guy L. Hunner secretary.

Primary Splenomegaly with Cirrhosis of the Liver.

Dr. W. Osler exhibited a case which he believed to be one of Banti's disease, an affection characterized by enlarged spleen, contracted cirrhotic liver and jaundice. A woman, aged 40, came in Aug. 3, 1898, with an abdominal tumor extending 17 cm. below the left costal margin, ascites and edema of the feet and legs. Hemoglobin 47 per cent., red corpuscles 2,500,000, leucocytes 2500. This tumor appeared eleven years ago when she first had malaria. The chills were repeated each spring for four years, the tumor continuing to grow during that period, but not increasing any since then. On September 30, she left the hospital, the hemoglobin being 50 per cent., the red cells

3,500,000, and leucocytes the same as before. There was no jaundice. On Sept. 30, 1901, she returned with jaundice of a month's standing, and pigment spots about the eyelids. The edge of the liver could be felt and was evidently cirrhotic. Blood examination: hemoglobin 75 per cent., red corpuscles 5,720,000, leucocytes 3470, coagulation time 5 minutes. The spleen extended 18 cm. below costal margin and was 15.5 cm. in width.

Removal of Foreign Body from Esophagus.

Dr. J. M. T. Finney exhibited a young man who had been operated on by Dr. F. 10 days before. He had swallowed a plate containing one tooth. It could be reached with a forceps, but the prongs of the plate were caught in the sides of the gullet and it was only forced further down. Esophagotomy was done, but renewed efforts again failed. The plate was now forced down to the cardiac orifice and a gastrotomy being done it could be felt with a finger passed up through the cardia, but could not be extracted. A bougie was then passed upward from the stomach to the mouth, and a sponge tied to it. This was then drawn downward and the cardia being dilated with the finger the plate was forced through it. The stomach wound was closed without drainage; the esophageal wound was packed with gauze and after a few days of liquid diet, recovery was complete.

Excision of Gall-Bladder.

Dr. Finney proposed a new method of operating, designed to avoid the raw surfaces which form adhesions with the intestines. He lifts a peritoneal flap, starting at the fundus, incising on either side through the peritoneal and muscular coats of the bladder and after separating these from the fibrous coat a short distance with the handle of the knife, easily dissects off the rest with the finger. After removing the gall-bladder the incision is carried through the peritoneum, making a cuff as in appendix operations. Then, covering the raw surfaces of the stump with this peritoneum, he draws the edges together with sutures. Four cases thus treated have all done well, but the operation is only adapted to selected cases.

Gunshot Wound of the Intestines.

Dr. R. H. Follis said the patient was shot in the abdomen with a 22-caliber revolver just after a meal, and two and one-half hours before admission to the hospital. The bullet entered to the left of the umbilicus about the middle of the rectus muscle. Incision was made in the course of the wound and three small perforations were found in the jejunum. These were closed, and the peritoneal cavity wiped out of the bloody fluid, but neither the source of the hemorrhage nor the bullet were found. The presumption was that there was a fourth perforation which took care of itself. The wound was closed with silver sutures and subcutaneous silk and a good recovery ensued.

Granulated Hernia with Gangrene of the Bowel.

Dr. Follis stated that since the opening of the hospital in 1889 there have been 11 cases of strangulated hernia with gangrene. Four of these were treated by immediate end-to-end suture after excision, with 3 deaths. Four others were treated by the formation of fistula after excision, with the idea of doing a secondary suture later. Two of these lived for the secondary suture and both died after this was done. In one other case the strangulated loop was thought to be viable and was returned, but the patient died. One case was operated on under cocain, the bowel being sutured to the abdominal wall and a second operation of excising the discolored bowel done after fifteen hours; end-to-end anastomosis was made and the abdomen closed. Chloroform was used and the patient died later of broncho-pneumonia. Case: Male, 71, admitted with right inguinal hernia of two years, strangulated for twelve hours. Immediate operation under cocain, constriction relieved and loop brought out of abdominal cavity, but not excised. Bowel was left to see if it would clear up. This not taking place in twenty-four hours, the gangrenous bowel was removed and end-to-end suture made with the Halsted bag. The operation was done without the peritoneal cavity and the twenty-four-hour adhesions were not disturbed or the gauze dressing removed until anastomosis was completed. The wound was then cleansed and intestine returned. The patient was exhibited.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Oct. 9, 1901.

Vice-President, Dr. Alexander H. Ferguson, in the Chair.

Open-Air Treatment of Consumption.

Dr. Homer M. Thomas said he was convinced that there was no climate which of itself would cure consumption. It was equally true that there was no climate suited to every case of consumption. Individuals differed materially in their powers of reaction; therefore, a climate that might be bracing to one would be exhaustingly cold to another. In some cases an equable climate was desirable, whereas a cool, bracing climate was more suited to others, although it should always be abundantly sheltered against wind and weather. Warm climates, as a rule, were unfavorable to consumptives. A mild, equable climate would suit the largest average of cases. There were certain features which were common to all rural localities in which consumptives were benefited. As a rule, they had pure air, free from dust and smoke, and the impurities which necessarily went with a dense population. They were fresh and bracing with excellent artificial protection against cold or storms. They had sufficient fine weather to render an outdoor life possible, and, lastly, the soil was well drained, dry and warm. Wherever these conditions were found and suitable arrangements could be made, it would be found possible to treat most consumptives with success. A high altitude, dry atmosphere, fine weather, equable temperature, or abundant sunshine were not all in themselves essential to success, although they might be especially desirable in individual cases. It was possible to treat most consumptives successfully at or near their own homes. Many consumptives were physically unfit to take long trips. Whenever there was fever, exhaustion after slight exertion, excessively free perspiration, a long journey was attended with risk. Physicians should seek for their cases the greatest amount of fresh, pure and open air. The patients should have cheerful surroundings; they should avoid reinfection and keep the gastro-intestinal tract in a high state of functional activity. Specific medical or therapeutic measures always sustained a secondary rôle. In addition to the variety of amusements that patients might be surrounded with, it would be found that useful occupations as well were never contraindicated. Gardening, like carpenter work, or, in fact, any avocation which could be pursued tentatively in the pure, fresh air, was valuable. The speaker was a strong advocate of the great beneficence of an open-air treatment, associated with all of the collateral hygienic measures. The open-air treatment of consumption was actively prosecuted in Germany, France, Switzerland, Russia, Norway and Sweden, England, and in many centers in the Eastern, Middle, Southern, and Western portions of the United States. His experience with the open-air treatment had been so favorable that he could quite heartily recommend a trial of it in all suitable cases.

Dr. Robert H. Babcock said that no one who had employed the open-air treatment of tuberculous patients for many years, could doubt the value and possibility of carrying it out at the homes of patients. He emphasized the importance of educating the profession in general on this point. It was possible to carry out this treatment with patients of sufficient means in the country 'round-about Chicago; but how to carry it out with a poor clerk, whose salary did not amount to more than $75 or $80 per month, was a question that had interested physicians in Chicago, because the majority of their patients were poor. However, it was possible to treat poor patients in the city of Chicago. If there was a balcony connected with the flat; if there was simply a yard with a few feet of space, or a vacant lot in the neighborhood across the street, either one of these afforded possibilities for carrying out the open-air treatment. It was the fresh air, the sun, and the out-of-door air that was needed. Dr. Babcock illustrated this

with the citation of a number of cases. He was a believer in climate because it afforded the possibility for patients to live out of doors without the same danger that they encountered here on the lake shore. Given a patient with sufficient means, who could command the attendance of a physician, and who would carry out his instructions to the letter, he would necessarily send that patient away. But given a person of limited means, who could not afford, in addition to every other expense, the attention of a home physician, particularly if he was sent to a suburb, and the physician had to spend two or three hours in making his visits, he would recommend sending such a patient to another climate where the possibilities were greater. He urged treating patients in Chicago who were suffering from consumption, no matter how poor they were. Give them the open-air treatment. If this could not be given perfectly, it should be given imperfectly. But give it.

DR. ARNOLD C. KLEBS stated that tuberculosis was such a chronic disease that if physicians attempted to treat it medicinally, large doses of drugs had to be given for a long period of time, which would affect digestion, and prove a failure. It was very fortunate that the open-air treatment and sanitary régime for this disease were being agitated. As to hereditary tendency or predisposition, he thought that the hereditary factor did not lessen the possibility of improvement or cure.

DR. JOHN A. ROBISON referred to the treatment of indigent tuberculous patients. He said that in Cook County there was an institution well equipped for the treatment of these patients; that the principal object for which this institution was erected had been frustrated by political methods. One of the principal things in the treatment of tuberculosis was a good diet for patients. At Dunning, he stated that 15 cents' worth of oatmeal was supposed to last the average patient a month. The patients were fed oatmeal and milk in the morning; at noontime they were given mush and milk, while in the evening they received a light dinner, with possibly a little piece of meat. The result was that the majority of the patients did not remain at the institution more than about two weeks; perhaps a few of them remained four weeks. A great many were walking patients, returned to other parts of the city and became new centers of infection. He urged the Society to exert its influence in carrying out the open-air treatment as advocated by the essayist.

DR. N. S. DAVIS, JR., said that the poorer people oftentimes moved to a more advantageous climate more readily than the wealthier ones, who were affected with tuberculosis. If somewhat ill with the disease, they quit work, and would either go to a hospital or seek some other climate; while men of wealth clung to their work for an indefinite length of time.

DR. DAVID J. DOHERTY suggested a change of vocation. Persons who worked indoors could be prevailed upon to get out of doors and fill positions, such as drivers on street-cars, peddlers, etc. He had often noticed a number of feeble men gathering up waste paper in the parks. If such positions could be obtained for patients with incipient tuberculosis, he believed it would be a help towards their speedy recovery.

DR. JOHN A. ROBISON reported in detail an interesting case of brain tumor.

Surgery of Pulmonary Abscess, Gangrene and Bronchiectases Following Pneumonia.

DR. D. N. EISENDRATH drew the following conclusions:

1. Both acute and pulmonary abscess and gangrene following pneumonia may develop immediately, and chronic and simple putrid abscesses, with or without bronchiectases, are more remote sequelæ of both croupous and influenzal pneumonia.

2. The most valuable points in the history are the etiology; the sudden expectoration after an apparent crisis of pure non-odorous pus in the simple abscess cases, or of fetid pus in the gangrenous variety. In the chronic cases there was usually a history of pneumonia having preceded the condition at some considerable time previously, followed by expectoration of large quantities of pus, with exacerbations of fever, accompanied by emaciation and frequently clubbed fingers.

3. Signs of cavity are seldom present. The moist râles, especially of large metallic character, are the most reliable physical signs. The character of the sputum is also of great value, whether purulent or fetid. Elastic fibers are more frequently found in gangrene than in abscess, being comparatively rare in the latter.

4. The *x*-ray is only of confirmatory value, as it shows chiefly thickened areas of lung, and should not be absolutely relied upon. When it shows a shadow at the same point where the physical signs are present, it is of value.

5. The prognosis of abscess and gangrene following pneumonia, medically treated, is not very favorable. Many cases of both varieties can be successfully treated in a surgical manner by pneumotomy. One of the greatest difficulties is the exact localization of the focus. The statistics which the essayist had gathered showed a marked increase in the percentage of recoveries, especially in the cases which have been reported within the last five years over that of the preceding five or even ten years. The prognosis for the chronic cases is not so favorable. The patients are usually operated upon when in an emaciated condition, and the walls of the cavity are often soft, so that they do not contract well after being drained, and the free communication of a bronchus with such cavities is also a great barrier. But statistics in this variety are also improving, especially when combined with excision of the affected portion of the lung.

DR. E. FLETCHER INGALS said that the diagnosis should be made accurately before operating. A certain amount of danger attended exploratory puncture in cases of pulmonary abscess, and that it was unreliable in many instances. No one would question the difficulties attending the diagnosis who had had occasion to study such cases for any length of time. As to operations for bronchiectasis, he thought it was well established that where there was more than one cavity, say two or three cavities, especially in a case of bronchiectasis following pneumonia, the results were usually unfavorable, as most of the patients died. The only case he had operated on of that kind was one in which he did not know there was more than one cavity present. He was not able to find the cavity he was searching for, but he found one of considerable size, cylindrical in shape, but the patient did not recover. He agreed with the essayist as to the necessity of operating on all cases when the diagnosis could be made, and when a reasonable time, say three or four weeks, had been allowed for the tissues about the cavity to have gotten in a more healthy condition. The majority of cases of abscess following pneumonia recovered. The difficulty of locating the cavity was very great in most cases.

DR. ROBERT H. BABCOCK discussed three points: 1. The location of the pulmonary cavity; he said one should bear in mind the fact that the cavity was likely to be located higher than expected. 2. One may be deceived into the belief that he had a pulmonary cavity to deal with following a pneumonic abscess, when, as a matter of fact, it might be a bronchiectatic cavity, or a system of bronchiectases, and the differential diagnosis was by no means easy. 3. Another point was with reference to empyema following pneumonia. This condition could usually be differentiated from pulmonary abscess, but it was not always easy to do so, by any means. This was particularly true when we had what not infrequently occurs—an interlobar empyema. A case was cited in point.

DR. CARL BECK exhibited a boy in connection with the discussion on Dr. Eisendrath's paper, who had, in succession, pneumonia, gangrene, abscess, with destruction of a large part of the left lung. The boy was operated on by him, and the abscess drained.

DR. EISENDRATH, in closing, said that medical treatment was useful in many cases. He had seen one case of acute gangrene following pneumonia the past year, the patient having recovered. Cases of abscess and gangrene were known to completely recover. Taking cases that became chronic, he thought the chances were far better with operation than without it. He thought it was impossible to differentiate a circumscribed empyema from an abscess or an interlobar empyema from an abscess.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Prescription Writing.

We purpose giving the fundamental principles employed in the writing of prescriptions. No apology is offered for taking up such an elementary subject, as we believe it will be appreciated by a large number of our readers. The whole subject will be discussed, including, in detail, the metric system.

A prescription is the written evidence of a physician's therapeutic ability. It is one of the things by which a physician, just beginning practice, is measured. Not alone are deficiencies in this art confined to the young man just out of college, but seeming carelessness among older practitioners covers up their ignorance and inability to write a prescription as it should be written. Suffice to say that there is not a sufficient amount of time allotted to the medical student in properly training him in the method of prescription writing. Too many prescriptions are allowed to go into print without the proper endings, and in indifferent language. A prescription is a written formula for medicines, with proper instructions for methods of compounding, to be followed by the druggist, as well as directions for administration to be observed by the patient or his attendant.

In writing a prescription both the ingredients—if it be a compound prescription—and the instructions to the druggist should always be written in Latin. While, as Thornton states, this is not imperative, yet there are many reasons why this should be carried out.

1. Latin is a language which will never undergo change, which insures perpetuity of the name given the drug.

2. Latin is understood in all countries and can thus be universally interpreted.

3. The Latin language should be used in writing prescriptions because it is best as a rule that the patient should not know what he is taking. There are a great many patients who claim that they are unable to take certain drugs, as for example quinin, calomel, morphin, etc., asserting that they are affected in certain peculiar ways by these several drugs. Should a physician prescribing for such peculiar individuals make the mistake which caused them, no doubt, to leave their former doctor, then he will probably be similarly disposed of. So that in such instances the Latin terms not only inspire the patient to the belief that he has derived benefit from the hydrargyri chloridum mite, whereas calomel would have done him great harm.

Another valuable point to be gained in using Latin is that in the pharmacopeia no official drug has two Latin names, while a prescription calling for "snakeroot" may mean "serpentaria" or "cimicifuga," etc.

PARTS OF THE PRESCRIPTION.

A compound prescription, to be complete and properly perfected, should be made up as follows:

1. The name of the patient, written in plain English.
2. The superscription.
3. The body of the prescription, or the names of the drugs to be prescribed, properly written in Latin.
4. The directions to the druggist, which should always be written in Latin.
5. Directions to the patient, which, as in case of the first, should be written in plain English, and with definiteness as to time and method of taking.
6. The physician's name plainly written.

The name of the patient should have an important place upon the prescription, so that no mistake will be made by any member of the household when more than one member are sick at the same time, and to enable the druggist to know whether the prescription compounded is aimed for an adult member of the family or an infant.

Treatment of Tic Douloureux (Trigeminal Neuralgia.)

The following is of service as recommended by Merck's Archives:

℞.	Butyl-chloral hydratis	gr. lxxx	5
	Dionin	gr. iv	25
	Alcoholis	ʒss	16
	Glycerini	ʒi	32
	Aq. destil. q. s. ad	ʒiv	128

M. Sig.: One dessertspoonful every half hour until relieved, or three to four dessertspoonfuls every four hours.

Dionin is said to produce no such bad after-effects as morphin, such as nausea, constipation, etc. It can be given in doses ranging from one-fourth to one grain.

Treatment of Neuralgia.

The following is recommended in the superficial forms of neuralgia:

℞.	Menthol	3ss	2
	Olei gaultheriæ	ʒi	4
	Tinct. capsici	m. x	66
	Ext. belladonnæ	gr. xxii	1 50
	Lani	ʒiv	16

M. Sig.: To be applied to painful area two or three times a day.

Treatment of Acute Mania.

In cases of acute mania with marked mental excitement, the following is recommended.

℞.	Hyoscinæ hydrobrom.	gr. 1/8	008
	Morphinæ sulph.	gr. ii	12
	Sacch. lactis q. s.		

M. Ft. capsulæ No. xii. Sig.: One capsule every four to six hours.

In these acute cases of mania which very frequently occur in young women the condition of the bowels and the blood must always be very carefully observed and corrected. It is not unusual in such cases to obtain marked improvement within a very short time by promoting elimination by the bowels and kidneys.

Carbolic Acid in Tetanus.

In a case of tetanus which developed in a young man of eighteen years of age, Dr. Louis Plessner of Bay City, Mich., reports recovery from the use of carbolic acid injections. The young man noticed stiffness of the neck, so he states, as early as the third day after stepping on a wire nail. The following injection was given:

℞.	Acidi carbol	gr. ii	12
	Glycerini		
	Aquæ, āā	ʒss	2

The foregoing injection containing 2 grains of carbolic acid was given twice a day, the patient receiving in all 63 injections. The physician states that the patient rested better in about one-half hour after the injection. He further states that the injection seemed to be fugitive in action. The kidneys were closely watched, as well as other symptoms of carbolic acid poisoning. The only indication was noticed in the odor of carbolic acid in the breath. The only other medicine given was a mixture of chloral and bromid during convalescence for insomnia present.

Treatment of Catarrhal Jaundice.

The bitter tonics along with dilute hydrochloric acid are recommended as tonics, antifermentatives and hepatic stimulants, The following combination makes an effective mixture in such cases:

℞.	Acidi nitro-hydrochlor.	ʒiv	16
	Tinct. nucis vom.	ʒiii	12
	Tinct. gentianæ q. s. ad	ʒiii	96

M. Sig.: One teaspoonful after meals three times a day in water.

The following is very often prescribed in cases of catarrh of the bile ducts:

℞.	Sodii salicylatis	ʒii	8
	Ammonii chloridi	ʒss	16
	Aquæ menth. pip. q. s. ad	ʒiii	96

M. Sig.: One dessertspoonful after each meal in water.

Treatment of Functional Hepatic Disorders.

The following combination is recommended by Lockwood:

℞.	Pulv. rhei	gr. viii	50
	Sodii bicarb	gr. xx	1 33
	Pulv. ipecac.	gr. i	06
	Tinct. nucis vom.	m. xx	1 33
	Aq. menthæ pip. q. s. ad	℥iv	128

M. Sig.: Shake, one teaspoonful before each meal.

Treatment of Vaginal Diseases.

Prof. J. C. Wood, in *Ther. Gazette*, is of the opinion that by means of the atomizer, medicaments can better be forced into the tissues than when applied locally by means of applicators. In the treatment of leucorrhea due to gonorrheal infection, he sprays the vaginal walls through a fenestrated speculum with a solution of hydrogen peroxid of 50 per cent. strength. The walls are then wiped thoroughly and the following applied as an antiseptic spray:

℞.	Acidi borici	gr. iv	25
	Thymol	gr. 1/16	004
	Sodii boratis	gr. i	06
	Sodii bicarb.	gr. ss	03
	Olei pini sylv	gr. 1/6	01
	Eucalyptol	gr. 1/10	005
	Olei gaultheriæ	gr. 1/10	005
	Olei piperitæ	gr. 1/10	005
	Alcoholis		
	Glycerini, āā	℥ii	64

If the secretion is mucous and tough, Dobell's solution is recommended. After spraying, the vaginal walls are kept apart by a tampon medicated with a 10 per cent. glycerin solution of ichthyol. After the removal of this the patient is instructed to take a douche of bichlorid 1 to 2000. The treat ment should be repeated twice a week.

Astringent Dentifrice.

Sabrazes, in *Jour. de Méd. de Bordeux*, recommends the following:

℞.	Saccharin.	gr. viiss	5
	Acidi benzoici	℥i	4
	Tinct. krameriæ	℥ss	16
	Olei menth. pip.	m. vii	5
	Olei cinnamomi	m. x	66
	Alcoholis	℥iii	96

M. Sig.: Use as a dentifrice.

Medicolegal.

Two Thousand Dollars for Flesh Injury to Foot.—The Court of Appeals of Kentucky holds, in Bowling Green Stone Company vs. Capshaw, that an award of $2,000 damages for injury to a man's foot could not be considered excessive where the flesh was torn and mashed, so that under the great toe and the ball of the foot flesh had to be cut off, it being shown that the injury was painful and permanent, and that the man lost much time from labor and would be a slight cripple for life, though no bones were broken or removed.

Eight Thousand Dollars for Loss of Leg Below Knee.—The Supreme Court of Iowa holds, in the personal injury case of Wimber vs. the Iowa Central Railway Company, that where a switchman in his 39th year and in good health, with an expectancy of life of 26 years, met with an accident necessitating the amputation of his right leg about six inches below the knee, and causing pain, suffering, mental anguish, loss of time, and decreased ability to earn usual in such cases, an award of $14,500 damages must be considered excessive, and all in excess of $8,000 must be remitted, if the judgment be allowed to stand.

Fifteen Thousand Dollars for Hip Injury.—The Supreme Court of Alabama holds, in Southern Railway Company vs. Crowder, that where a passenger was thrown from her seat and hurt by a violent jerk of the train, the evidence tending to show that among the serious hurts which she sustained there was a fracture of a bone in the hip joint, in the treatment of which she was for several weeks kept prostrate with a weight suspended to her foot, and that this hip injury had resulted in impairment of her general health, and a stiffening and shortening of her leg to an extent which would thenceforth deprive her of its natural use, a verdict for $15,000 could not be said to be excessive, the jury being authorized to award for recovery a sum which would furnish reasonable compensation for these injuries and the suffering naturally attendant thereon.

Fixing of Compensation for Postmortem Examinations.—The New York statute provides that "a coroner shall have power, when necessary, to employ not more than two competent surgeons to make postmortem examinations and dissections and to testify to the same, the compensation therefor to be a county charge." Under this statute, the Court of Appeals of New York holds, in the case of Foy vs. Westchester County, the coroner has no power to fix the compensation of a physician whom he employs to make postmortem examinations. In this case, which was an action brought by a physician to recover for postmortem examinations made by the direction of a coroner, the physician alleged that the county had "audited and allowed for each of said postmortem examinations the sum of $10," from which the court assumes that he presented his claim to the board of supervisors, which made the audit. Continuing, it says that the board had jurisdiction to audit the same, and its audit was final, not having been reviewed or reversed upon certiorari, as it is termed, and was payable at the amount audited by the county treasurer upon the physician's presentation of the proper warrant or certificate of the supervisors. The allegation that the amount of the audit was "not the value of his services" might state a case for a review of the audit by certiorari, but not a cause of action. Wherefore, the court affirms a judgment in favor of the county, based on a dismissal of the complaint.

Spitting or Coughing of Blood.—In the case of Peterson vs. the Des Moines Life Association, the assured was asked in her medical examination whether she had ever had any "spitting or coughing of blood," and answered "No." There was, however, evidence that on various occasions prior to the giving of this answer the assured did spit blood, and the jury so found in response to a special interrogatory. But the trial court, in its instructions, limited the inquiry to the question whether the assured was subject to spitting or coughing of blood, and the Supreme Court of Iowa holds that this was proper. It says that the inquiry must be given a reasonable construction, and such construction would limit it to such spitting or coughing of blood as a reasonable person might suppose to indicate some ill health or physical condition affecting the desirability of the applicant as a risk. It would surely not be expected that the applicant should answer as to spitting of blood by reason of the extraction of a tooth or accidental biting of the tongue. The finding of the jury that the assured had spit blood, was, therefore, not conclusive. The jurors may have found, under the evidence, that she had not spit blood in such a sense as to show that her answer was fraudulent. The same reasoning, the Supreme court says, disposed of the complaint of the association in this case as to other answers of the assured with reference to previous ill health and accidents. It was for the jury to say not only whether such answers were untrue, but also whether, if untrue, they were fraudulent.

Kleptomania—Opinions of Experts.—Kleptomania, according to the Supreme Court of Iowa, in the larceny case of State vs. McCullough, where the defense was insanity, is an irresistible desire to steal. It is, as it understands it, a weakening of the will power to such an extent as to leave the afflicted one powerless to control his impulse to appropriate the personal property of others, without regard to whether such impulse is inspired by avarice, greed, or idle fancy. Then, practically, the whole defense in this case resting upon the opinions of experts, who were men of a high degree of skill and long experience in treating mental ailments, the court holds that, while the jury were to pass upon the weight of the opinions in the light of all the facts, they should have been permitted to take such opinions fairly, and consider them without detraction by the court. And, inasmuch as it says that the Supreme court as now constituted, would not, if the

question were a new one, approve the reasoning employed in the Hockett case (70 Iowa, 446), where expert testimony was more or less discredited, it states that it is not inclined to apply the rule announced there to any save a similar state of facts. In that case the witnesses testified, as appears from the opinion, wholly in response to hypothetical questions, while here two of the experts had personally examined the defendant, and one of them based his opinion in part on the facts learned through such examination. This, it thinks, was a material distinction, and, it holds, made the criticism approved in the Hockett case unwarranted and erroneous when contained in an instruction to the jury in this case.

1. **Creosote in Pneumonia.**—A number of cases are reported showing the benefit of the use of creosote in pneumonia. The formula advised is:

℞. Creosot. carbonat. .....ʒss
Sapon. medicat. 3l

M. F. capsulæ No. 60. Two to be taken every three hours, ten to twelve daily.

Weber maintains that it exerts a remarkable beneficial and uniform influence on pneumonic patients, and asks whether it is really a remedy for the disease. He does not think the beneficial qualities are due to antipyretic or bactericidal action and holds that it must be antidotal to pneumonic toxins.

4.—See abstract in THE JOURNAL, xxxvi, p. 1726.

5. **Basal Cerebral Lesions.**—Perry reports three asylum cases in which interesting postmortem findings occurred. The first was one of acute mania where there were no paralyses nor localized symptoms. There was an area of softening, involving the posterior two-thirds of the lenticular nucleus, and the posterior half of the caudate nucleus. The fibers of the capsule appeared to be normal, as were the thalami and the remainder of the basal ganglia and other portions of the brain. The second was a case of terminal dementia in which there was a sudden attack of spasm of the left side with loss of consciousness, death occurring twenty-five minutes later. There were two small hemorrhages in the optic thalamus of the right side, one the size of a pea and the other about one-fourth as large. Both were situated in the posterior part of the thalamus. No other lesions existed to account for the condition. In the third case, an epileptic suffering from chronic mania for years, the patient died from enteritis without any localizing symptoms. There was a cystic tumor of the pineal gland, making it about four times the size of the normal organ, but no degeneration of the brain tracts whatever. He thinks the following conclusions may be drawn from the cases: 1. The corpus striatum—caudate and lenticular nuclei—has no intimate relation with either the motor or the psychical spheres. 2. There may be a very extensive lesion involving both the caudate and the lenticular nuclei without giving any symptoms. 3. There is in the posterior portion of the lateral nucleus of the optic thalamus an area, irritation of which will produce immediate loss of consciousness with convulsive movements upon the opposite side, and destruction of which will produce immediate death. 4. There may be a tumor of considerable size involving the pineal gland without giving any pressure symptoms. 5. The pineal gland may be entirely destroyed by disease without producing symptoms. 6. There is no tract of nerve fibers originating in the pineal gland and connecting it with the remainder of the brain.

6. **Spinal Curvature.**—The conclusions of this second article by Lovett are in substance as follows: In cases of scoliosis with fixed bony curves, the same corrective treatment can not be applied as in cases of flexible curves. The fact that there is

a fixed portion of the spine situated between two movable parts makes it easier to twist or displace the thorax as a whole than to make any change in the curved portion itself, hence forcible attempts to correct bony rotations in fixed curves will increase the lateral curve unless the thorax is kept from rotating, and forcible attempts to correct the latter curves are likely to increase the rotation. Suspension apparently has little corrective effect in rigid cases, being more likely to affect the compensatory curves than to produce improvement in the rigid curve itself. For the application of forcible jackets the prone position with the legs hanging perpendicularly seems most effective for two reasons: 1, because in the prone position, greater side displacement between the vertebræ is permitted on manipulation than in the suspended position, the spine not being put on a stretch, and elasticity thereby exhausted, and, 2, because in the prone position, with the legs hanging perpendicularly, it is possible to apply a jacket which shall flatten to some degree the lumbar curve of the spine and when the erect position is assumed this flattening of the lumbar spine will necessitate some degree of hyperextension in the dorsal region on account of the equilibrium of the spine. When the effect of rotations of the spine, and their effect on lateral deviation is better understood, it may be possible to add the element of rotation to the corrective forceps applied in the treatment of scoliosis. With regard to forcible correction one or two things may be done: 1. Force, carefully antagonized, may be applied to the curve itself. 2. The curved region may be twisted as a whole, or displaced sideways as a whole, in its relation to the rest of the spine. The first is the more desirable when possible, but the latter may be of much use in improving the general outline of the body. The separation of the two is important in intelligent therapeutics. It is relatively easy to displace the thorax in relation to the rest of the column, but relatively hard to change the curve itself. Forcible correction seems to have its place only as preliminary to gymnastic treatment, and the author does not advocate the use of corrective plaster jackets except as a temporary means to secure a better foundation for gymnastics or, if necessary, for mechanical treatment.

7. **Intermittent Hydrops.**—Taking a case as their text, Brackett and Cotton review the symptoms and the literature of this disorder. They say it seems we have here an affection without a discoverable anatomical basis, without proof of infection, giving a simple non-inflammatory serous effusion in the joints, occurring at regular inexplicable intervals, interrupted without rule, or in accordance with what we may term psychic stimuli, associated in some instances with what are usually classed as functional nervous disorders. The disease seems to be a functional, as opposed to an organic trouble, and whether we do or do not call it a vasomotor neurosis depends upon our choice of words. The therapeutics of the disorder is bewildering, and it is hard to formulate treatment, but it seems fair to infer that quinin and arsenic, and electricity should be tried, and if no result is achieved, after a time allowed for the chance of spontaneous remission, puncture and injections or open drainage may be resorted to. A rather extensive bibliography, largely taken from Benda's exhaustive monograph on the subject, is appended.

8. **Splenic Anemia.**—In his concluding paper Wentworth summarizes his conclusions: 1. The blood changes are those of secondary anemia varying in different cases. 2. The degree of cachexia does not always correspond with the blood changes. The percentage of hemoglobin is frequently over 50 per cent., the number of red corpuscles is often more than 3,000,000, and it is obvious that the cachexia does not depend on these conditions. He suggests as probable that the cachexia and other symptoms are produced by a chronic intoxication, similar to that of cancer, tubercle, etc., and that the splenic and blood changes are merely two of the results produced. The source of intoxication is unknown and may be multiple. 3. It is not easy to see how fibroid changes in the spleen can produce toxin. There is no analogy between the liver, kidney and spleen. An overgrowth of connective tissue in the spleen can not produce symptoms, and the functions of the spleen are in no way analogous to those of the thyroid gland and suprarenal capsules. 4. If it were possible to produce toxic substance by fibrous tissue, it is difficult to account for the absence of such in connection with chronic hyperplasia of the spleen from various causes. In these cases the splenic lesions are identical with those described by Banti as characteristic of anemia splenica. 5. It has been said that splenic alterations are primary, but this requires more facts to confirm it. The splenic lesions are characteristic of chronic hyperplasia. 6. The splenic lesions in so-called splenic anemia do not warrant the statement made by Banti and others that it is related in any way with pseudoleukemia. There is no analogy between the hard glandular form of malignant lymphoma and the lesions of chronic splenic hyperplasia. There is also considerable uncertainty as to the nature of the hard form of malignant lymphoma, and its classification is discussible. 7. A tendency to generalize from observations of one or two cases is to be deplored. In splenic anemia nothing characteristic of a primary disease has been discovered in any organ or in the blood. The few cases unquestionably show a diverse etiology. The investigations have been incomplete and most of the statements depend on clinical observations. Banti's own cases prove the varied etiology. 8. The evidence is conclusive that anemia infantum pseudoleukemica is a secondary anemia, and that it owes its peculiar symptoms and blood changes to the occurrence of severe anemia at an early age. 9. There is little doubt that anemia infantum pseudoleukemica and anemia splenica infettiva are identical conditions and there is less proof that anemia splenica infettiva is a primary disease of the spleen than that the other is a primary condition of the blood. 10. There is no apparent connection between the character of the blood and the splenic changes in infancy. Identical lesions in the spleen show varying degrees of anemia, sometimes marked and sometimes very slight changes in the blood. The degree of leucocytosis varies in the same way. 11. These differences can not be explained by the duration of the condition in many cases. All that one can say about these secondary anemias of infancy is that in some cases there occurs a chronic hyperplasia of the spleen, and in others not. 12. The names anemia splenica, primary splenomegaly, anemia splenica infettiva, and anemia infantum pseudoleukemica are objectionable because they are misleading. Anemia splenica has been used for many years as one of the synonyms of pseudoleukemia and should not be used to describe conditions that are in no way related to pseudoleukemia. No evidence has been furnished justifying the use of the term "primary" in splenomegaly. The same may be said of the word "infettiva" in connection with the infantile form of splenic anemia. Anemia infantum pseudoleukemica is a secondary anemia of infancy, and is no way related to pseudoleukemia. A very complete bibliography is appended to the paper.

11. **Southern California.**—The general conclusion of Fiske's article is that the Southern California climate is as soothing as that of Colorado is stimulating. There seem to be two distinct seasons in hotel life there. In the winter come the tourists from the East, in the summer the migration of the Californian himself. He has been generally told that summer is the preferable season of the two.

12. **The Mouth in Infancy.**—The method of examination of the mouth in childhood is described in detail by Sobel, who would conduct a systematic examination as follows: A depressor is inserted in the left angle of the mouth, the cheek and lips everted, then at the right angle and the cheek and lips everted. The spatula then catches the frenum and the under surface of the tongue, the frenum and the floor of the mouth are observed. The spatula being removed the upper surface of the tongue is viewed; the latter then firmly depressed and the hard and soft palate, fauces, tonsils, pharynx and, in the vast majority of cases, the epiglottis are observed. The first step —eversion of the cheeks and lips—being the least disagreeable, gains the confidence of the patient for the more uncomfortable examination of the tonsils and pharynx. He points out the different conditions which will be revealed by each step of the operation and suggests as an ideal means of holding the child

to have it rest against the mother's right breast, its head against her shoulder, the left hand holding the child's knee's and her right its hands. The right index finger and thumb are placed on the infant's temporal region, and with the palm the head is held firmly against the mother's shoulder. The importance of good light is mentioned. Direct daylight thrown into the mouth answers every purpose and subdued light is rather more satisfactory than bright sunlight. At night it is always well to examine with a forehead reflector or an especially constructed pocket electric lamp.

14. **Suprarenal Capsule Tuberculosis.**—From experiments on rabbits De Vecchi finds that by tuberculosing the suprarenals a serious poisoning of the animal is produced, ultimately fatal. The circulating poison has great destructive properties, as shown by pathologic changes in the heart, liver and kidneys, and the cells of the central nervous system are particularly vulnerable. These explain the nervous symptoms of those suffering from Addison's disease. Secondary changes of the sympathetic, even where the celiac ganglion was apparently destroyed, were not observed. He has not been able to produce any skin pigmentation in his experiments. The lungs, the alimentary tract, the pituitary glands, the thyroid and ovaries show no tubercular changes.

15. **The Physician as a Social Factor.**—The fact that no physician was selected for a place in the Hall of Fame, and the general lower social position of the profession as compared with the two other learned professions are dilated upon by Rovinsky, who explains the facts by the deficient preliminary education and the commercial tendencies of so many members. The need is of a united profession that will take a more active part in the social and political affairs, better registration of the profession and representation in its legislative assembly and better *esprit du corps*. We have let things go of themselves too much, and have cultivated individualism to our damage.

16. **Staining Accidents.**—Cobb reports the observation of what appeared to be a new bacillus, a rod about three times the size of the tubercle bacillus and shaded light-blue, while using methyl instead of methylene blue as a contrast stain in sputum tests. Instead of a bacillus he found it was really a crystal of the stain, and he calls attention to the need of care in the use of gentian-violet, methyl-violet, rosanilin and Sudan iii, especially on sputum work.

17. **Mental Impression and Malignant Disease.**—Bryant has studied the subject of mental depression on the incidence of cancer, reviewing the literature, especially the statements that it may act as an exciting cause for the latter. It appears from his investigation that there is little evidence to warrant the assertion that mental depression exerts any influence in the causation of cancer except from blood impoverishment, which almost invariably exists in melancholia. The preponderance of malignant manifestations in the female should be attributed rather to the broader field of attack than to any form of special vulnerability.

18. **Tuberculosis.**—Repp concludes his article by summing up the evidence as it appears to him that tuberculosis may be transmitted from animals by eating meat or being inoculated with it, also that it may be transmitted through milk of tuberculous cows or by inoculation of the same, both when the udder is diseased and when it is healthy. The meat and milk of certain tuberculous animals contain living virulent tubercle bacilli. Tubercle bacilli of cattle are pathogenic to man, hence he concludes that the meat of such animals is unfit to eat if highly tuberculous, but is safe if only slightly so, especially if well cooked and the tuberculous tissue eliminated. Milk from tuberculous cows is always bad if the udder is infected unless thoroughly sterilized and if the udder is apparently not infected it still should be looked on with suspicion. Tuberculous cows may be kept for breeding purposes if they are isolated even from their own offspring, and their products sterilized before use or they may be slaughtered for food under conditions imposed as stated above. All legislation and regulation should favor the disposition of tuberculous animals as suggested above.

19.—See abstract in THE JOURNAL of July 13, p. 134.

21. **Tuberculosis Among the Jews.**—Fishberg goes over the statistics, especially of New York City, as to tuberculosis in the Jews and credits the apparent immunity to the precautions specified in the Jewish ritual as regards food, especially meat, and the relative infrequency of alcoholism and syphilis in the race.

22.—**Cremation.**—Fulton's article is a plea for cremation as opposed to burials, using the well-known arguments and also the economic ones of less cost to the individual's estate and family.

23.—See also ¶30.

24. **Croupous Pneumonia.**—Croupous pneumonia more than any other disease, as Wilson remarks, demands a very large series of cases to determine the efficiency of any kind of treatment, and he advocates the expectant stimulating and supporting treatment. The method of the German Hospital in Philadelphia is outlined. The diet consists chiefly in milk and light broths, though some variety is allowed in small amounts. When the patient takes from one to two pints of milk and a pint of chicken or mutton broth every twenty-four hours it is regarded as sufficient. Water is given freely but in small amounts. Under ordinary conditions the patient is sponged night and morning, the temperature being regulated by the sensation. If the bodily temperature exceeds 104 F. cold sponging may be repeated at intervals of two to three hours and in the early course of the attack two or three large flat ice-packs are applied to the affected side for the purpose of making the patients feel more comfortable. Alcohol is given, in the majority of cases ordinarily not over 4 to 6 ounces of whiskey in twenty-four hours, though larger amounts may be given to patients accustomed to its use. A calomel purge is commonly given on admission—in fractional doses if there is nausea and vomiting. Opiates are used for pain generally in the form of Dover's powders in 2 or 3 grain tablets, diminishing towards the close of the attack. Cardiac sedatives are seldom given, digitalis sometimes in response to direct indications. As a rule strychnia is given as a cardiac stimulant, and the nitrites, especially nitroglycerin, especially for the relief of the laboring right ventricle. If these measures fail and small mucous râles and cyanosis occur, venesection is indicated. If pulmonary edema supervene, atropin is given hypodermically, often with apparently good results. Dyspnea is combated with oxygen, well diluted with air. Dover's powders will control the nervous symptoms to some extent, and increase in the quantity of alcohol together with cold applications to the head and neck. Neither poultices nor cotton jackets are allowed. The patients wear a moderately heavy, loose-fitting merino undershirt. At the crisis the patient is carefully watched, and if the Dover's powders have been discontinued, a hypodermic injection or an opium suppository is administered. In some cases ammonium carbonate, alcohol or hot coffee seem indicated. Collapse is very rare. During convalescence an abundantly nutritious diet is given. Bitter tonics are sometimes employed, and there is no hurry about the patient's getting out of bed.

25.—See abstract in THE JOURNAL of November 9, p. 1260.

29.—See abstract in THE JOURNAL of October 5, p. 934.

30. **The Lane Lectures.**—This eighth lecture by Morris reviews the nervous disorders of the skin, their mechanism, nature, treatment, etc. A large part of the lecture is given to the subject of itching, which he does not attempt to fully explain. The other subjects mentioned are urticaria, dermographism, stigmata and hysterical edema.

31.—See abstract in THE JOURNAL of October 5, p. 935.

33. **Gunshot Wound of the Abdomen.**—After reporting two cases Baldwin gives his comments, and maintains that, at least in civil practice, every gunshot wound of the abdomen should be followed up at the earliest possible opportunity and every bit of clothing or extravasated matter and if possible the bullet itself be removed; while if penetration has occurred, the proper closure of the intestinal wound will give the patients practically the only chance.

34. **Alcohol.**—Rooney reports here briefly the experience of Kane Summit Hospital, which has been a temperance institution for a number of years and where the results of the disuse of alcohol have been most encouraging. She thinks the effects of the agent are those of a sort of "nerve tooler" and brain paralysant and that it is utterly useless as a tonic or a food.

36. **New Disease.**—Carhart describes a disorder which has no marked prodromal stage, commencing with a nervous chill, intense pain in the back and abdomen, but not with the usual malarial pyrexia and sweating. Soon after the rigor sets in the head becomes intensely hot with acute pain, usually beginning in the medulla oblongata and extending over the top of the head to the forehead. There is extreme restlessness, but rarely loss of consciousness, though occasionally delirium. The general temperature rises, but not in proportion to the cerebral heat. The tongue is coated with the thinnest possible, delicate, bluish-white coating, not foul in any part; no red lines or margins; not usually flabby with indentations. Thirst is almost absent; water seems to aggravate the prevalent slight nausea. There is almost complete anorexia, and emaciation is rapid. The bowels are more or less constipated, the kidneys little damaged, occasionally slight albuminuria, no sugar. The disease does not seem to be contagious. All the cases occurred in the early autumn, after a hot, dry summer. A resemblance to cerebrospinal meningitis is noticed, but there were no spots or streaks of congestion on the face, forehead or ears and some other differences, no spots or patches. The tongue is different. Quinin seems to aggravate the condition and the best treatment in his experience has been the use of mild laxatives, potassium bromid for the nervous symptoms, and cold water to the head with occasional hot footbaths. The gradual flow of cool water on the head seems to have the best effect. Absolute quiet and freedom from all excitement must be maintained. He does not report the proportion of fatalities, though it does not seem to be usually or generally fatal from the tone of his remarks.

41. **The Stereognostic Sense.**—From a general review of the subject, Mettler concludes that our knowledge of the position of the limbs is in all probability the result of a cortical association and interpretation of numerous afferent impulses in the muscles, articulations and the skin, in all of which are found sensory tactile end organs. The prominence of one or other set of afferent impulses in the production of the stereognostic sense depends whether the parts are in active movement or are at rest. The necessity of activity or rest in perception depends largely upon its nature. In most cases the space and pressure sense will have to be employed, involving a sensation of movement, hence the deep tactile organs concerned in the so-called muscle sense will come into play. On the other hand the limb may remain at rest and be able to give us knowledge of a stream of water moving over it or of the movements of a feather, so that we can tell the nature of these objects where the skin organs are employed. In any case the sensation is primarily one of touch. The locality of sensation is of minor importance. Astereognosis is hardly a very definite localizing symptom; it merely indicates a false perception resulting from an alteration in the central perceptive apparatus or in the paths, but in conjunction with other symptoms it may prove to be of the greatest value.

42. **Psychology of Neurasthenia.**—Kiernan's paper, though not long, is rather an elaborate consideration of the subject, which can best be appreciated by reading.

51. **Fibroids in Pregnancy.**—The dangers and advantages of myomectomy during pregnancy are detailed by Cumston, who thinks that direct operative treatment during pregnancy for the removal of fibroids is rarely indicated and that it is better to wait until labor before operating. In a few cases it is probably better to interfere during the puerperium when the child has been expelled without operative interference. Premature labor artificially induced should be rejected. According to the conditions the surgeon will choose between conservative myomectomy and the radical operation. As regards the obstetric aspect of the question, he would say that the forceps should never be applied to overcome any impediment caused by fibroids and he thinks that version is a deplorable recourse. The question whether to wait or operate is important and where the pelvis is completely blocked and the impossibility of a natural labor is evident, Cesarean section should be resorted to before the birth canal has become too distended and unfavorable conditions have arisen.

54. **Cesarean Section in Placenta Previa.**—Zinke analyzes the statistics and holds that Cesarean section and Porro's operation are perfectly legitimate and elective procedures in all cases of placenta previa, central and complete, and especially so when the patient is a primapara, when the os is closed and the cervix unabridged; when hemorrhage is profuse and can not be controlled by tampons, and separation of the placenta around the internal os is difficult or impossible. There are exceptional cases and perhaps even a small majority of placenta previa cases that can be treated successfully in the manner of Fry and DeLee, but the value and importance of the child's life must be considered.

59. **Incipient Tuberculosis.**—In order to establish the very first indications or "the skirmish line" of tuberculous infection, Tyndale says we must watch for the following: 1. Progressive and persistent anemia, unaccounted for by other conditions, especially stomachic or intestinal indigestion. This last, if existing, should be removed before a positive diagnosis is entered on. 2. Progressive and persistent emaciation with the same exclusions as above. Frequent weighings alone are to be relied upon. He calls attention to the entire occlusion of the thoracic duct curve by tuberculous nodes as enough in itself to account for the rapid progressive anemia and emaciation. 3. The earliest auscultation and percussion sounds. Seek for the changes of rhythm in breathing and do not wait for the changes in pitch, the interrupted rhythm, the broken or the "ragtime" rhythm. The percussion findings give no clue to the condition, save in confirming by its normality that no organic change leading to alteration of pitch or of quality has as yet taken place.

60. **Alcohol in Phthisis.**—Preble objects to the free use of alcohol, but says it would be a valuable remedy if all the possibility of misuse were guarded against. Generally speaking, it is not longer given when the indications can be filled by other remedies.

61. **Tuberculodermata.**—Aronstam emphasizes the fact that the various tuberculides are merely a local indication of a general tuberculous dyscrasia or a cutaneous manifestation of the undermining destructive, imperiling and ravaging action of the tubercle bacilli, which may at any time favor the entrance of pulmonary, meningeal, or peritoneal tuberculosis. Hence we should treat the tuberculides just as we treat cases of tuberculosis of other organs, employing all possible means, prophylactic, mechanical or medicinal, to ameliorate incurable ones and to eradicate those which can be done away with.

64. **Vibratory Massage of Drumhead.**—Schwabach has experimented with vibratory massage in 173 cases, 103 of which were bilateral affections of the auditory organs, in a total of 276 affected ears. He found the method of slight apparent advantage in cases of sclerosis. The cases do not warrant a favorable prognosis if the first application of massage is followed by improvement only, and an unfavorable prognosis was given when the improvement was insignificant. In a large proportion of cases improvement was not permanent. He had 22 cases of chronic middle-ear catarrh and in these the results were not favorable. In subacute middle-ear catarrh permanent improvement of tinnitus and acuteness of hearing occurred in 16 or 44.4 per cent.; in 13 or 36.1 per cent. no permanent result was obtained. In the remainder permanent improvement was obtained by combined treatment with massage. Inflation or massage after treatment by either method alone failed. In 6 out of 11 ears with influenza complicated with middle-ear infection the final result was much improved, and in 26 cases of chronic middle-ear suppuration there was improvement in the subjective noises in 22 out of 24 affected ears and improve-

ment in hearing in 16 out of 36 ears. There was improvement in both tinnitus and hardness of hearing in only 18 or 50 per cent. Briefly stated the results of his operations are as follows: Among 43 cases of sclerosis of the middle-ear improvement in hearing was obtained in only 4.9 per cent. where the impairment of hearing had not reached a high degree, while a permanent cure of subjective noises occurred in 28.3 per cent. The best results were in the sequelæ of chronic suppuration of the middle ear. In 91.6 per cent. there was complete recovery or notable improvement in the subjective noises and unpleasant sensations, and the hearing power of the patient improved in only 55 per cent. In cases where precise diagnosis could not be made, the results of massage were not good enough to justify further trial. He would recommend the method in patients suffering from subjective noises to such a degree as to render them unable to attend to their business, but he thinks it does very little good in sclerosis. It is also to be recommended in cases of simple chronic hypertrophic middle-ear catarrh with dulness and retraction of the drumhead, also in subacute middle-ear catarrh, in influenzal otitis, and in sequelæ of chronic purulent otitis media where the customary treatment fails in relieving the subjective noises and the power of hearing. In pronounced cases of idiopathic affections of the sound-perceptive apparatus, massage, so far as his experience goes, promises no results whatever.

65. **Otogenous Meningitis.**—A number of cases are reported by Cohn, who considers the clinical diagnosis, which is often impossible. Lumbar puncture is the only means of recognizing it distinctly and is almost always followed by relief of the patient, but recovery will always be exceptional. The most important measure is prophylaxis.

66. **Retropharyngeal Abscesses.**—Formerly these abscesses were supposed to depend on injuries of the pharynx and esophagus, on caries of the cervical vertebræ, affections of the retropharyngeal lymphatics, etc. To these causes Kien adds otitis media suppurativa, both acute and chronic, and reports three cases. When pus is once occluded in the middle ear it strives to make its way out, and if it can not escape externally it may burrow along the bone or any bony openings. It may escape upward through the tegmen, as in Kessell's case, and then enter the middle of the posterior cranial fossa, and escape downward through the foramen rotundum or ovale. It may escape by the jugular foramen and along the basilar bone to the anterior side of the spinal column and downward, but the direct paths are more often followed. It may cut down through the floor of the antrum or along the anterior wall of the meatus or through the posterior antral wall into the cranial fossa and from there proceed downward. The routes may be partly preformed (vascular channels) or they may represent the neoplastic perforations. The occipito-mastoid suture may favor extension of pus and there may be still other routes. The diagnosis of such abscesses is easy as soon as the pharyngeal wall bulges, and when the pressure on the external cervical region causes pus to well up from the meatus. They may cause very serious disturbance, pain in the neck, difficulty of breathing and if they are not opened or do not evacuate spontaneously, suffocation may follow. Gravitation abscesses extending to the mediastinum have been seen in neglected cases. The external incision is imperative if the abscess lies beneath the cricoid cartilage, or in other words, so deep that it can not be reached by the knife from the inside. In Koenig's opinion the external incision is indicated in every case as the only safe way to avoid infection. He makes the incision on the outside of the neck on a level with the inferior thyroid artery, if the tumor has gravitated so far. Open along the inner margin of the sterno-cleido, on a level with the larynx, on the inner side of the thyroid vessels, keeping close to the larynx until the medial side of the carotid is reached, where the connective tissue of the pharyngeal space is encountered. Chiene makes the incision along the posterior margin of the sterno-cleido-mastoid, and enters the abscess cavity from the anterior wall of the spinal column. Kien thinks if the fistula is already present in the pharynx, if the abscess is not too large, or if there seems to be the least possibility of working from the mastoid opening without running the risk of gravitation or retention, it is sufficient to make a broad communication between the abscess and the mastoid opening, and to conduct the after-treatment from this opening.

67. **Thrombo-phlebitis of the Superior Longitudinal Sinus.**—The superior longitudinal sinus is in close relation with the posterior frontal sinus and inflammation of the latter may extend by thrombo-phlebitis to the superior longitudinal sinus. The symptoms may be local or general, the latter are pyemic. The local changes may be divided into intra- and extra-cranial. The former will be situated below the frontal and parietal bone and may be overlooked. The intradural changes are present in every case and lead to death, through circumscribed, one or double-sided meningitis of the convexity. "Thrombo-phlebitis of the superior longitudinal sinus after frontal sinusitis may be divided into the following stages: 1. The prodromal stage: symptoms of sinusitis, fever, severe frontal headache. 2. The initial stage: pain in the parietal region. 3. Stage of regional abscesses (the disease has not become generalized): clinical appearances varying according to the site of the extra- or intra-cranial abscess and the presence with the latter of general brain symptoms. 4. Pyemic stage: rigors, remittent fever, pulmonary complications, splenic tumor, etc. 5. Terminal stage: meningeal symptoms developing after one to four days. The terminal stage may follow directly on the initial stage (fulminating course). Stages 3 and 4 may appear simultaneously." It would be of the greatest aid to therapeutics if the initial stage gave us some characteristic signs of involvement of the superior longitudinal sinus. At present we have only the parietal pain in this stage. If the abscess is situated extra-cranially, the diagnosis can be made from it. The differential diagnosis between abscess originating directly from the frontal sinus and indirectly by means of the superior longitudinal sinus and meningitis, can be made only after opening the skull and making a diagnostic puncture. The pyemic symptoms are directly referable to this sinus, but the meningitis can originate independently. A rapid case can be explained only at autopsy. It is very important that, in all autopsies on persons dying of intracranial complications after a frontal sinusitis, the superior longitudinal sinus should be carefully examined, and if found diseased, all the veins leading to the various abscesses must also be carefully investigated. The treatment is analogous to that of thrombo-phlebitis of the transverse sinus after suppuration of the middle ear. Before the onset of a diffuse purulent meningitis, recovery may be possible, but the chances are not favorable.

71. **Intranasal Operations.**—Denker advocates the use of the galvanocautery in intranasal operations as avoiding hemorrhage and the necessity of the tamponade.

72. **Aural Polypi.**—From an examination of 60 aural polypi by various staining methods Bruhl concludes that 78 per cent. of these are not tumors but are inflammatory tissue formations. The minority are tumors, and according to histologic structure, aural polypi are to be divided into polypoid granulations—partly fibromatous—and myxo-fibromas.

74. **Tuberculosis of the Nasal Mucous Membrane.**—After reporting 5 cases, Hinsberg remarks that these illustrate the various changes which follow nasal tuberculosis. 1. There may be some dacryocystitis without any evidence of tuberculous lesions, with symptoms of disease of the lachrymal sac. This is least harmful and is easily treated, though, according to Seifert, it is the primary stage of severer lesions. In these cases the causal connection is overlooked if the nose is not examined. 2. An evident tuberculous disease of the lachrymal sac is present. 3. The conjunctiva and cornea are affected by the transmission of infectious material if the dose does not cease at a certain time. This may be (a) inflammatory due to irritation of the secretion, but not to tubercle bacilli. Manifest disease of the lachrymal passage may be absent; or (b) of specific tuberculous nature, usually in the form of infiltrations on the conjunctiva, which may extend to the cornea. These are usually situated in the neighborhood of the punctæ lachrymales and connect with the lachrymal sac by a fistulous

tract. 4. The secretion of the tuberculous lachrymal sac may leave the conjunctiva intact, but causes tuberculous lesions in the surrounding skin of the eyelids. In all these cases the fistulæ are present showing the path of infection. In most cases the granulation tumors can be easily removed by a snare, or the thermocautery and curette. Lactic acid on a tampon left in place for hours may aid some if concentrated. The tampon should be applied not only to the diseased area but also to the surrounding tissues. Lactic acid attacks only diseased skin and mucous membrane. He thinks systematic treatment carried over a long period of time is advisable, and if nasal tuberculosis is not seriously complicated by morbid conditions and if treatment is carried over a sufficient length of time the prognosis is not unfavorable. Untreated there is danger of its extending to other parts, even the lungs.

76.—See abstract in THE JOURNAL of September 14, p. 711.

77.—Ibid., p. 712.

78.—Ibid., p. 713.

79. **The Nasal Septum.**—The various pathologic conditions of the nasal septum, deviations, dislocations, ridges and spurs, hypertrophy, atrophy, hematoma, ulcer, vascular dilatation, synechia, tumors, tuberculosis, syphilis, etc., are described by Freeman. He thinks the chief cause of deviations and probably of many other deformities is the lack of development of the hard palate and gives his reasons in detail. This deformity of the palate he thinks may be due to adenoids in many cases.

83. **Anilin Oil.**—After reporting a case where bad effects were produced by the patient's use of anilin oil, by local absorption, and a review of the cases in the literature, Dupuy concludes that the chances of injury from this agent thus applied are small and that it can be used in the hands of the physician for operative work on the drum and contiguous parts, but we can not with impunity place so toxic and so readily absorbed an agent as anilin in the hands of patients for the purpose of frequent instillations.

84. **Tonsillar Abscess.**—The points Goldstein emphasizes are: 1. That acute abscess formation in the tonsil per se is extremely rare. 2. That our knowledge of the place of entrance of infection into the peri-tonsillar tissue is still uncertain. 3. That the many measures thus far suggested to abort this condition have been unsuccessful. 4. That early surgical interference, even before pus formation has been established, is our best prophylactic procedure.

96. **Ovarian Pregnancy.**—Webster notices the recently reported cases, especially that of van Tussenbroek, but doubts whether the explanation given by her is entirely correct. He thinks that the fertilized ovum in the human subject can begin its development only in tissue derived from the Müllerian tract, and her claim that the ovum was fertilized in its follicle is not, he considers, proven.

104. **Chlorosis.**—McCaskey thinks that we have an oligemia as well as an oligochromemia and oligocythemia in chlorosis, and that iron acts in a special way, and suggests the possibility of some sort of mechanical or chemical influence on the intestines favorably affecting the digestive processes and that its markedly beneficial action in the treatment of chlorosis is indirect. He also specially calls attention to the value of hydriatic treatment, rest in bed in cases where it appears to be indicated, open-air exercise, and properly graded gymnastics begun at the right time. Suitable selected hydriatic measures, at least in severe and impracticable cases, would appear to him, together with the use of iron and forced feeding, to give us the best results.

109. **Alcoholism.**—The practical treatment of inebriety is comprised in four essentials, according to French: 1. Breaking up the habit of drinking. 2. Removing the morbid craving. 3. Freeing the system from the effects of drink. 4. Influencing the moral nature to perpetuate the cure. In breaking up of the habit of drinking, the first thing to do is to get the patient's consent and co-operation, and to find a remedy which will counteract relaxation, tone up the nervous system, stimulate cell activity, though not as a substitute for alcohol, but rather an antagonist, opposing its effects throughout the whole sphere of its action. Elimination should be stimulated to activity. There must be a sedative for the delirium, insomnia and excitement, remedies for the gastric catarrh, etc. The first of these indications is best filled by strychnin, which may be added to and supplemented by that of atropin. It exalts the function of the spinal cord, increases intestinal peristalsis and aids elimination. Atropin calls the vasomotor centers into action and affects the nerves of taste, leading to distaste for alcoholic liquors. Apomorphin is valuable for emptying the stomach of alcohol and sobering up and is also of value to produce nausea and disgust at the sight, smell or taste of liquor. It should be given without the knowledge of the patient, hypodermically with other injections. The proportion of strychnia and atropin recommended by the author are one-sixth to one-fourth of a grain of sulphate of atropin, 1 gr. of nitrate of strychnia, with 4 gr. of boric acid in an ounce of sterile hot water. Of this the average dose is 10 minims, but it may be a little higher, according to the effect produced, given four times a day. The dose of strychnia is intended to be one-half of the amount required, the remainder being given by the mouth. For internal medication, a simple bitter tonic is the chief essential. Other remedies may be added for the action of the liver and otherwise. As a considerable proportion of alcoholics are also syphilitics, it is well also to make provision for this element, and he thinks that any good gold chlorid does is in this way. Of the sedatives the combination of bromid, chloral, and hyoscyamus is of service, and where there is a busy, talkative delirium, hyoscine hydrobromate hypodermically is indicated. When a patient has lost the morbid craving for alcohol and normal appetite begins to reappear, the cure is well under way, but in no case is it sure. Two-thirds of the cases at least he believes have relapses or will do so in the end, and he thinks that 33 1/3 per cent. is a very fair percentage of cures in conditions of such seriousness as chronic inebriety.

114.—See abstract in THE JOURNAL, xxxvi, p. 1726.

115.—Ibid., p. 1727.

121. **Phytolacca.**—The advantages of phytolacca in various conditions are enumerated by Shoemaker, and he names the preferable preparations, the fluid extract and tincture, the dose of which ranges from 5 minims to a fluid dram. It is very depressing if given in too large a dose, and it is an undesirable remedy as an emetic. Its effects are of value as an alterative in certain constitutional maladies. It has a use in puerperal mastitis, and engorgement and inflammation of the lymphatic glands, in seborrhea, violent inflammation, acute eczema and tonsillitis, and has a field of usefulness in syphilis. It has also been of value in chronic rheumatism and some physicians recommend it in cases of inoperative cancer as retarding the growth. He thinks the profession generally should give the remedy a more careful study than it has perhaps received.

132. **Appendicitis in Life Insurance.**—The conclusions of Weill-Mantou's article are as follows: "1. Any abnormal sensitiveness in the appendicular region justifies postponement. 2. Applicants are admissible when cured by operation, a few weeks after interval operations; after three or four months when the resection has been done during an attack; in eighteen months or two years when the applicant has been cured by the simple opening of a purulent collection about the appendix. It will always be best to require a statement from the operator or from a physician present at the operation, giving the precise nature and the results of intervention. The same conclusions will hold in cases of circumscribed peritonitis with spontaneous evacuation of the purulent collection. 3. Any typhlitis, appendicitis, appendicular colic or crisis, however slight, acknowledged by the applicant or suspected by the examiner, will subject to a postponement of two or three years. 4. Two or more attacks will require a more lengthy postponement, which will be proportionately increased according to the number and severity of the attacks. 5. The research of family antecedents will be considered as an important element of great moment in the younger applicants. 6. In cases of remote an-

teceding attacks of appendicitis, the examiner must carefully investigate the existence of signs which might reveal the slightest awakening of the old appendicitis. 7. Every case of chronic and of recurring appendicitis must be rejected."

British Medical Journal, October 26.

The Communicability of Human Tuberculosis to Cattle. SHERIDAN DELEPINE.—Four experiments with calves are reported; only two survived long enough to allow definite results to be obtained. In the first case it was thought probable that the calf suffered from congenital tuberculosis; the experiment, therefore, is inconclusive. The second calf was inoculated with 5 c.c. of mixed tuberculous human sputum on August 1, injected subcutaneously on the inner side of the right femorotibial articulation, and died on August 7. There was enlargement of the lymphatic ganglia on the inoculated side, fibrinous peritonitis, enlargement and congestion of the spleen and a small amount of pleural exudates existed. Microscopic examination of the gland showed tubercle bacilli, and inoculation experiments on the guinea-pig from this subject caused tuberculosis. The case might, therefore, be given, Delépine says, as an instance of rapid infection of the lymphatic ganglia at a distance of five inches from the seat of inoculation, but he considers the experiment inconclusive as there was a possibility that the bacilli found in the precrural gland might have been carried from the seat of inoculation to the gland without multiplying and be still sufficiently active to infect the guinea-pig without being necessarily infective for the calf. The cause of death in each of these two cases was a general infection with a bacillus present in the sputum which caused acute septicemia, which could also be produced in guinea-pigs. The third calf was given 50 c.c. of mixed sputum in its food for one day. Death occurred twenty-eight days later. There was no trace of tubercle in the organs excepting in those connected with the alimentary canal and multiple tubercle bacilli were found in the esophageal glands. The cause of death was infection similar to that of the first two calves, but he holds that the case creates a strong probability that the tuberculosis of the glands had been caused by the ingestion of tuberculous sputum. The fourth calf had 5 c.c. of sputum injected into the peritoneal cavity. There was no evidence of tuberculin reaction twenty-six days after inoculation, but one occurred sixty-eight days after, and the animal was slaughtered seventy days after inoculation. Marked tuberculosis of the peritoneum extending gradually to the pleura and pericardium was found. No other organs were infected with the tubercle excepting a few of the lymphatic ganglia connected with the peritoneum. He considers the last two cases were sufficient to indicate the probability of tuberculosis having been introduced as the result of ingestion or peritoneal infection with human tuberculous sputum. It should be stated, however, that none of his calves were subjected to any tuberculin test before the experiments. He says that tuberculosis is exceedingly rare in calves and if there may be a certain amount of truth in the view that tuberculin has a preventative action, it would be illogical to inject a calf with tuberculin prior to such experiments.

Results Obtained by Anti-Typhoid Inoculation in an Epidemic of Typhoid Fever. A. E. WRIGHT.—This article is an analysis of an epidemic of typhoid which occurred in the Richmond Asylum, Dublin, with special reference to the results of inoculation. The results of the investigation is stated in tabulated form and show that in 298 average population of uninoculated, there were 30 cases of typhoid with 4 deaths, giving a percentage of cases of 10, and the deaths as 1.3 per cent. With the average population of 339 persons inoculated there were five or six cases with one death, giving a percentage of cases of 1.5, and of deaths .3 of 1 per cent.

The Role of Toxic Action in the Pathogenesis of Insanity. W. FORD ROBERTSON.—The question discussed by Robertson is how far toxic action is the cause of insanity, and he maintains that it is the primary etiologic factor in all cases where there are not, 1, inherent defects of the cortical organisms inconsistent with normal development; 2, physical causes which directly injure the cortical neurons, more especially traumatism; 3, deficiency of materials necessary for nerve-cell metabolism; 4, in some cases where the insanity may be due to sensory impulses. In some of the primary toxic cases the determining factor is a series of sensory impulses, but there are good reasons for believing that in many of these cases where depression or physiologic emotion passes into distinct mental disease there has already been a toxic condition which of itself might not be sufficient to disorder the cerebral metabolism, but became capable of doing so under such stimulus. He insists particularly on the importance of auto-intoxication from the gastro-intestinal tract as the chief factor in the pathogenesis of a large number of acute and chronic diseases, including several forms of mental disease. Among these a large proportion of cases of general paralysis, alcoholic and senile insanity, dementia precox, and most cases of chronic mania and melancholia. The great majority of cases of insanity are not primarily diseases of the brain, but are dependent upon the action of toxins derived from elsewhere which affect the functional activity of the cortical nerve cells by destroying their metabolism and even permanently damaging or destroying them.

Colitis or Asylum Dysentery? THOMAS CLAYE SHAW.—The author contends that asylum colitis is not a bacterial dysentery, as some have thought, but is due to a condition of nerve degeneration tending to ulceration of the bowels, occurring in the insane, especially on account of their disordered general metabolism, their irregular habits of overfeeding and taking into their systems of substances which are liable to produce trouble. It is quite possible that it may be due to some toxic condition set up in the individual. The presence of bacteria does not always indicate that these are the cause of the presence of the disease. During the conditions of lowered vitality in the mentally diseased the bacteria are apt to be in evidence more than in other cases where insanity does not exist.

A Plea for the Occasional Performance of Depression in Cases of Cataract. HENRY POWER.—The use of depression in certain cases is advocated by Power, who reports the experience in India, where it is often performed by ignorant natives with often brilliant results. The cases in which he thinks it would be advisable are: 1. Those where otherwise any operation would seem dubious, as in persons greatly enfeebled by age or other infirmities. 2. In cases where there are physical obstacles for the extraction operation, such as extremely small palpebral fissure or deeply-seated and small eyes. 3. In cases where there is a troublesome condition of chronic conjunctivitis which does not yield to treatment. The condition can be temporarily rendered aseptic and small puncture offers less danger of injury to the internal portions of the eye than would more extensive incision. 4. There is a complication of cataract deafness, in one case of which he regretted that he did not endeavor to depress instead of performing extraction in the usual way. The patient interfered with the bandage, and severe inflammation followed, with loss of the eye. He thinks it would have been better had he depressed and kept her in bed one day and then allowed her to go about. 5. Other cases where depression would probably give better results than extraction are in lunatics, imbeciles, and idiots in whom interference with the bandages are liable to occur; in old, flat, flabby and phlegmatic patients, who are specially liable to complications. 6. Chronic bronchitis may be a complication in old age which would interfere with the ordinary cataract operation. 7. There are cases where there is softening or liquefaction of the vitreous, and the lens easily shifts its place. If a large cut is made the vitreous flows away with the lens. 8. Another class of cases where depression may be performed is when one eye has been unsuccessfully operated upon. If the patient has suffered much he may refuse to submit to a second extraction, but would be in favor of depression, and lastly, in the extremely rare hemorrhagic diathesis where few would case to use knife treatment. The objection that irido-cyclitis and septic inflammation might occur is valid only in case of the breaking up of the lens, he thinks, and the operator had better discontinue the operation if that occurs. Glaucoma may occasionally follow depression, but it can be generally met by the use of eserin, or if necessary an iridectomy. He thinks the danger is somewhat exaggerated.

Bulletin de l'Academie de Medicine (Paris), October 8.

Negative Role of the Hypophosphites. MASSOL.—If some sodium phosphate is poured into a glass containing calcium hypophosphite and the fluid is rendered alkaline, a tricalcic phosphate is precipitated and the fluid contains sodium hypophosphite in solution. In experiments and tests on dogs and on two clinical subjects, the same process occurred. Calcium hypophosphite administered by the mouth is not altered in the stomach on account of the acidity of the gastric juice, but in the intestines it is decomposed with the phosphates from the food, and tricalcic phosphate is precipitated, which is eliminated in the feces and is lost to the organism. Sodium hypophosphite remains in solution and passes into the circulation. But it is not utilized, as it is incapable of being oxidized, and the entire amount is refound in the urine in the form of a hypophosphite. Consequently, calcium hypophosphite administered medicinally not only fails to benefit the organism, but directly aids to deprive it of a quantity of phosphoric acid corresponding to the weight of the calcium administered.

Chloral as a Vesicant. BONNET.—If chloral hydrate is spread on a diachylon plaster and applied to the vaselined skin, the part begins to burn in fifteen minutes. The plaster is then removed and the part covered with cotton. A phlyctena forms and the patient drops to sleep. Bonnet uses about 3 gm. of the chloral for a plaster 12 by 15 cm. in size. The subsequent slumber proves that the substance is more or less absorbed.

Treatment of Ozena by Methylene Blue. BONNET.—Five patients were cured of ozena in three or four weeks by daily irrigation of the nasal cavities with methylene blue in the proportion of 2.5 gm. to the liter of water. The irrigations were made three times a day at first. Except for the stain on the nostrils and upper lip, this method of treatment has no disadvantages.

Gazette Med. Belge (Liege), October 10.

Application of Hypnotism in the Education of Vicious or Degenerate Children. BERILLON.—Kleptomania, onanism, moral perversity and onychophagia can almost invariably be cured in children by hypno-pedagogic measures, even when the children have long been considered incorrigible. Bérillon urgently advises the more general adoption of hypnotism for this purpose, although he thinks it should be kept in the hands of practiced neurologists or alienists, and never used except after the failure of other measures. It aims to re-educate the will and create actual psychic inhibiting centers. The effect of this hypno-pedagogic treatment has always been durable in his experience. In kleptomania there seems to be an entire lack of inhibiting power. This can be created in the child by bringing him after he is hypnotized, to a table on which some money is lying. "You see the money. You want to take it. Very well, take it if you wish and put it in your pocket." The child takes the money. "This is what you usually do, but now you are going to put the money back and you will always do this henceforth. You will be ashamed that you have stolen and you will hasten to restore what you have taken." After a few seances of this mental gymnastics the child is permanently cured of his bad habit. He treats onanism by having the hypnotized child raise his arms, inducing an actual psychic paralysis in them, informing him that this paralysis will recur whenever he is on the point of yielding, at the same time using the most convincing moral arguments to inspire horror of the habit. Inveterate biting of the nails is frequently a sign of degeneracy. He treats it on the same principles as above. Hypno-pedagogy is more successful, the greater the intelligence of the subject. It is inapplicable to idiots and imbeciles. The automatic, reflex impulses which in normal children yield to moral suasion and ordinary measures, in degenerates are extremely tenacious. Waking suggestion has no influence on them, but wonders can be accomplished by this "mental orthopedics." This communication was one of the addresses at the fifth international congress of criminal anthropology, recently held at Amsterdam.

Progres Med. (Paris), October 5 and 12.

Parasitic Sclerosis of the Lungs. G. ARTHAUD.—Whenever there is marked decrease in the vibrations of the walls of the thorax, not to be explained by some extrapulmonary lesion, it is due to some zone of sclerosis, and the older the lesion the less vibration. As the sclerosis becomes older, the dulness increases and it becomes complete by the end of twenty years. A tubercular lesion passes through four phases in its development. The first is that of embryonal infiltration, with a transient and general obscurity to auscultation, resembling the characteristics of senile respiration, always dependent upon diminished elasticity of the lung. The second stage is the adult tubercle with giant cells, and auscultation reveals a roughness and exaggerated vesicular murmur, resembling exaggerated puerile respiration, due to excessive elasticity. In passive congestion or inflammation, and in edema of the lung, these two phases of auscultation appear in a reversed order. The third stage is that of caseous transformation and suppuration. Auscultation discloses that the respiration has ceased to be vesicular, and is becoming discontinuous, with râles and predominance of the souffle. The lack of continuance in the respiration is characteristic of every profound lesion of the lung, in the same way as the regression of the muscle tissue before the fibrous tissue is the base of the anatomic alterations in the organ. But the final disappearance of the elasticity of the organ is only the first phase in the evolution of sclerosis. As the fibrous lesion passes into the fourth stage of the tubercular process, the souffle becomes less intense and vanishes completely by the end of twenty years. The discontinuous respiration persists, the souffle fades away into total obscurity. When the sclerosis is less than five years old, the souffle predominates; between five and ten the souffle is of normal intensity; between ten and fifteen there is obscurity, and from fifteen to twenty, extreme obscurity or absolute disappearance. Palpation, percussion and auscultation therefore give different results according to the age of the "scrofula of the lung."

Bulletin de la Soc. Med. des Hop. de Paris, August 1.

Differentiation of Variola and Measles by the Blood. J. COURMONT.—In every case of smallpox, mild or severe, suppurative or hemorrhagic, from the first invasion to the commencement of convalescence, there is a mononucleosis invariably comprehending a certain proportion of myelocytes and of nucleated red corpuscles. Even in case of a complication inducing polynucleosis, the diagnosis is still possible by the presence of myelocytes. The tests reported in this communication show that this formula of the composition of the blood never occurs in measles.

Congenital Facial Paralysis. A. B. MARFAN.—At the autopsy of an infant of four months who had exhibited during life unilateral facial paralysis, with a deformity of the outer ear, the facial nerve on that side was absent except inside the cranium, and the existing portion was atrophied. The primary trouble had probably been in the petrous bone—an osteitis or arrested development—and this had arrested the development of the facial nerve and ear, while the intracranial portion of the nerve had developed, although undergoing secondary atrophy.

Congenital Facial Paralysis. J. COMBY.—Three infants with congenital facial paralysis observed by Comby, seventeen collected by Cabannes and one recently reported by Lagrange, presented more or less marked involvement of the eye in the paralysis. Forceps had not been applied in the delivery of any of the children in these cases, but the paralysis simulated obstetrical facial paralysis. It is incurable and is probably of nuclear origin. The ophthalmoplegia may predominate and entail the loss of the eye. There was no apparent hereditary taint in any of the children, such as syphilis, tuberculosis or traumatism during pregnancy.

Revue de Chirurgie (Paris), October.

Spinal Cocainization. KALLIONZIS.—It is impossible to compare chloroform general anesthesia and spinal cocainization, but each has its special indications and its well-defined sphere of usefulness. Kallionzis urges surgeons to abandon their hesitancy and reserve and cordially adopt spinal cocainization according to Tuffier's technique, as a precious addition to the means of anesthesia at our command for certain cases. He

has operated with it, or assisted when it was being used, in 110 operations, and is convinced that it deserves the attention and favor of all surgeons.

Goundou or Anakhre. MENDES and JEANSELME.—A bony, spongy tumor, ovoid and symmetrical, growing at the root of the nose, affects the negroes of the west coast of Africa, who call it "goundou." It usually appears before puberty and interferes with vision and respiration by its encroachment on eye and nose. Headache, epistaxis and a muco-purulent nasal discharge accompany its inception, but the general health does not suffer. Mendes reports a case, the first observed in Brazil, distinguished by the fact that the tumor was unilateral. Extirpation of the tumor is the only effective treatment.

Tuberculosis of the Female Generative Organs. MARIE GOROVITZ.—The details of fifty cases personally observed or collected in the literature, including several theses, are given in this comprehensive article, which is concluded from the five preceding numbers. The conclusions of the writer's research are summarized as follows, after premising that tuberculosis of the genital organs is far more frequent than formerly supposed. Modern methods of histologic and bacteriologic research, supplemented by inoculation of animals, have disclosed the presence of tuberculosis in many cases in which formerly it would not have been recognized. Although it is often secondary, yet it may be primary, and it is of the utmost importance to diagnose it in its incipiency. Examination of the secretions and of the particles obtained by curetting will render the greatest services in case of tuberculous endometritis. The latter is usually secondary and almost always tuberculosis of the tubes is the primary source. Tuberculous lesions of the tubes induce more or less pronounced reaction on the part of the peritoneum, in particular a variety of peritonitis with an encysted effusion, formerly called "young girls' ascites." In the course of a laparotomy on account of a tuberculous peritonitis, the annexes should always be carefully examined. It will frequently be found that they are the primary source of infection and they should be ablated if possible, preferably by the abdominal route. The extirpation should be far-reaching, and this extensive opening of the abdomen, while it removes the source of the affection, will have the most favorable influence on the peritoneal lesions. Bouilly has performed twelve operations of this kind with twelve recoveries, the cures persisting for seven, four and one-half, four, and two years. These results proclaim the value of radical and comprehensive surgical intervention. The details of these twelve operations are described in full in the course of the article. In genital tuberculosis the infection may arrive from above or from below. The former is most frequent. The clinical facts reported establish the possibility of tuberculous infection from the husband. The presence of tubercle bacilli in the sperm of phthisics explains this method of contagion. The experimental research reported also demonstrates that the tubercle bacillus deposited without traumatism on the mucous membrane of the genital apparatus, is capable of colonizing there and inducing the lesions characteristic of tuberculosis.

Opening the Antrum of the Petrous Bone for Mastoid Suppurations. O. LENOIR.—Antrectomy is recommended by Lenoir both as a complete operation in itself and also as the preliminary to other operations indicated by complications of suppuration of the middle ear or mastoid cells. It is easy to establish certain landmarks for the intervention, and injury of important organs can be avoided with almost certainty. It provides easy entrance into the base of the skull for treatment of cerebral or cerebellar complications of inflammation of the middle ear. The technique of antrectomy is similar to that of the Stacke operation, only in the reversed order. It allows complete oversight of the antrum, while in the latter operation the entrance but not the termination nor even the direction of the attic can be examined. Hammond has reported three cases of facial paralysis after operating by Kuster's technique. In Chaput's method of extensive resection of the petrous bone, the facial nerve is constantly menaced and paralysis has several times resulted. The aim of the operation is the same as in antrectomy, but the technique is much safer in the latter. Abscesses in the brain of otitic origin are nearly always close to the petrous bone. In children they are usually temporosphenoidal, sometimes cerebellar, very rarely beyond these regions. The petrous bone will have to be treated in any event, and therefore it is more rational to commence the intervention at this point and work through the antrum, utilizing the cavity already provided. Another advantage over trephining is the superior drainage.

Centralblatt f. Bakteriologie (Jena), September 16.

Vitality of Buried Typhoid Bacilli. W. RULLMANN.—In some of the tests of buried typhoid bacilli which are reported, the bacilli were found alive and virulent after having been buried for nine and sixteen months in sterile soil. The bacilli died rapidly in nine tests with unsterilized dirt, but in two others they were found living after a hundred days.

September 21.

Agglutination of Yeast Cells. A. MACFADYEN.—The serum of animals injected with the juice of compressed yeast cells (Buchner's "zymase") acquired the property of agglutinating yeast cells in turn.

Raising the Melting Point of Nutrient Gelatin. H. J. VAN'T HOFF.—The addition of one drop of 40 per cent. formalin to ten grams of gelatin raises the melting point so high that even boiling water is unable to dissolve the gelatin. Van't Hoff has found that one part of formalin to 1750 parts gelatin produces a gelatin which does not melt below 104 F. in the water bath.

Behavior of Bacteria in the Bodies of Immunized Animals. S. J. GOLDBERG.—Animals artificially immunized against the pyocyaneus and typhoid bacilli proved more resistant to secondary infection with anthrax and typhoid bacilli than the control animals. Typhoid bacilli injected into the body vanished in the course of four to eight hours. They assembled first in the liver, where they were devoured both by the endothelial cells of the liver and the leucocytes. Later they were found most numerous in the spleen in the animals immunized against the pyocyaneus. The bacilli collected in the bone marrow instead of in the spleen in the animals immunized against the typhoid bacilli. The bone marrow in the latter case probably constitutes the chief means of defense of the organism against bacterial invasion. The serum of the animals thus treated did not appear to possess any antitoxic properties.

Centralblatt f. Chirurgie (Leipsic), October 19.

Pendent Pelvis for Operations Close to Diaphragm. G. KELLING.—The organs under the diaphragm can be brought plainly into view and completely exposed by drawing the patient to the foot of the table and allowing the pelvis and legs to hang over the edge. The position is the same as that in which the cadaver is placed for the dissection of the diaphragm. It will be found of inestimable advantage in extensive operations on the stomach and upper surface of the liver. Kelling uses a Stelzner operating table which has a sliding top. The patient's trunk is fastened by a strap over the shoulders crossed behind the back. The leg holders are arranged to hold the thighs, and the spine is bent in the lumbar region. The ordinary longitudinal incision should be supplemented by a transverse incision starting at the tip of the twelfth rib. The intestines must be packed in with a napkin to prevent their falling forward, and the napkin fastened to the skin with peritoneal forceps or by sutures. An assistant maintains pressure on the intestines with one hand, and with the other retracts the costal arch. An iron band is fastened to each side of the table forming an arch over which a cloth is thrown to separate the abdomen from the anesthesia proceedings. The personnel should be trained in the rapid and aseptic change from the horizontal to this pendent position in the course of an operation if necessary.

Centralblatt f. Gynaekologie (Leipsic), September 14.

Value of Cocain in Obstetrics. F. WESTPHALEN.—Tedious, difficult delivery can be promoted and hastened by cocainization of the pelvic floor. It does not suppress the true labor pains,

but actually strengthens them, while at the same time it arrests the reflex inhibiting influences which are protracting the birth process. Westphalen has found that after a suppository of 3 cg. cocain has been introduced into the rectum the labor pains become regular, the pauses tranquil and delivery follows in a comparatively brief time. His experience with this measure in the last two years has been extremely satisfactory. The labor pains become regular in five or ten minutes after the suppository has been introduced. No toxic effects were observed in any case, but he established by personal experience that 3 cg. of cocain in the rectum induced slight mydriasis for half an hour, and consequently, he has never surpassed this dose, but has occasionally repeated it in one and a half hours.

October 5.

Infection of Parturients by Bath. WINTERNITZ.—Stroganow's assertions of the danger of infection from fluids entering the vagina during the bath have not been confirmed by Winternitz' tests. He states that a copper bath tub, cleaned and then rubbed off with alcohol, used only once, and the patient's external genitalia afterward disinfected, is absolutely harmless. He found that the bath water did not penetrate into the vagina in any of his tests with colored water, etc.

Value of Cystoscopy in Tuberculosis of the Female Bladder. W. STOECKEL.—Two observations of chronic tuberculosis of the bladder are reported, which do not present the slightest symptoms, and were supposed entirely cured, but the cystoscope shows that the tubercular lesions are progressing. In another case a circumscribed vesicular edema is developing around the orifice of one ureter on a tuberculous basis.

October 12.

Mechanism of Hydrorrhea in Pregnancy. K. REIFFERSCHEID.—The membranes must have ruptured at an early date in the case described, allowing the fetus to escape into the body of the uterus, where it continued to develop. The liquor amnii continued to form, but instead of collecting in the bag of waters, trickled out of the uterus, causing the hydrorrhea.

Deutsche Med. Wochenschrift (Leipsic), October 17.

Symphyseotomy and Cesarean Section. A. MARTIN.—In the case described a moderately contracted pelvis was complicated by unusual hardness of the fetal skull. Symphyseotomy was performed, but even with this, extraction of the fetus was impossible and secondary Cesarean section was necessary before delivery could be accomplished. This is not the only observation of the failure of symphyseotomy that has been published, and Martin concludes that symphyseotomy does not stand on the same plane as Cesarean section, on account of the fact that the aim of the operation is not always realized, while Cesarean section is always sure of success. He has applied Fritsch's fundus incision in four cases and comparing the results with those obtained with the ordinary incision in twenty other cases, he considers the former superior. The danger of adhesions is no greater than with the ordinary incision, while the wound can be more easily sutured.

New Facts in Regard to the Biologic Test for Blood. E. ZIEMKE.—The new Uhlenhuth-Wassermann serum test for blood can be obtained, Ziemke has found, by treating the animals with blood from cadavers. The serum obtained from the animals later was only a very little less effective than when blood from living subjects had been used for the preliminary injections. It was able to induce an almost instantaneous cloudiness in the dissolved blood in a proportion of 1 to 30. Uhlenhuth has recently had a large number of specimens of blood sent to him for examination, and he was able not only to differentiate human blood, but could also state the animal from which the blood was derived in the other specimens. Attempts to preserve the serum for future use showed that the addition of a little chloroform will preserve it for a time, but that it gradually becomes less and less effective. The serum can be desiccated and the globulin thus derived has the same properties as the fresh serum, but loses its efficacy in time. Ziemke has obtained the reaction with this "dry serum" three months old, but without the exact precision of the fresh serum. The formation of flakes is the true criterion of the test. The mixture of animal blood with human blood does not affect the reaction. The preliminary injections offer less chances of infection if made subcutaneously than into the peritoneum. The most important item in Ziemke's article is his discovery of a method of applying the test to blood so old and altered that it is insoluble in the ordinary media. He accomplishes this by dissolving the blood in a concentrated solution of potassium cyanate, then neutralizing the alkaline fluid by adding a few crystals of tartaric acid, carefully testing with red and blue litmus paper until the neutral reaction is almost reached. The fluid is then poured off and filtered. It remains turbid if the least trace of an excess of acid is present, but if faintly alkaline it is clear. It is then diluted with water until yellowish red in color, when it is ready to respond to the serum test. Blood from the stomach of a cadaver that had been buried for ten years and was mummified to parchment, was treated in this way, and the typical reaction promptly obtained.

Report of the German Sanitariums for Tuberculosis. ENGELMANN.—The 18th volume of the German Imperial Health Department contains the statistics of the 49 sanitariums in Germany from the beginning of 1899 to the middle of 1900. The total inmates were 6273, the number of beds 4000. At present there are 60 sanitariums with 5000 beds. More than three-fourths of the patients were committed by the sickness insurance societies and one-tenth by the "Krankenkassen," benevolent societies and lodges. Only one-fifth of the patients were women. The previous environment had been favorable in 56 per cent., medium in 32 and unfavorable in 12 per cent.; 45 per cent. were in the thirties and 27.8 in the forties. In 34.7 per cent. some grandparent, parent or brother or sister had had pulmonary tuberculosis. In about 50 per cent. the disease was of less than one year's duration. The average length of treatment was 92.4 days. About 50 per cent. remained in the institution three months. More than 50 per cent. had been engaged in an occupation causing inhalation of dust, metal, coal and glass dust, other organic substances, wood and wool dust, in the order named. About one-third of the patients were in the first stages of tuberculosis. The private sanitariums had the most severe cases. Of the entire number of patients only 7.4 were reported cured, but improvement was evident in 88 per cent. Bacilli were found in the sputa in 53 per cent. on entrance, and in 40 per cent. on dismissal. Fully 67 per cent. of the dismissed patients were able to resume their occupation, 7 per cent. engaged in a new occupation, 15 per cent. were able to partially resume work and only 11 per cent. were incapacitated for earning their livelihood. The total number improved has increased by 3 per cent. in the last fiscal year, owing to more careful selection of cases. Improvement occurred in 95.2 per cent. of those in the first stages of the disease; in 89.9 per cent. in the second and in 71.5 per cent. in the third stages. The working capacity of the dismissed patients rapidly decreased, until after six months only one-fifth were able to continue their occupation, and after three and one-half years, four-fifths had died or become entirely incapable of working. One-fourth of the total number had died after one and one-half years had elapsed, and more than 50 per cent. after three years. The proportion is a little better among those dismissed as capable of resuming work. At the expiration of one year after dismissal more than 50 per cent. were still working. After the lapse of two years the majority were dead or incapable of earning their livelihood. After the lapse of eighteen months only 75 per cent. were still alive, and after three years less than 50 per cent. The proportion of cases of persisting improvement is somewhat better among those dismissed as able to resume work. Less than 50 per cent. are still capable of working, but they were able to continue their occupation for three or four years. The figures from the first years of the sanitarium movement show that 45 per cent. are still capable of working after four years. After the first year it was 95 per cent.; after the third year 80 per cent. A remarkable fact was learned by the latest investigation, namely, that quite a number of those patients in the second or third

stages of the disease who had been dismissed as unimproved and incapable of working, were able to resume their occupation after a certain length of time. This is probably due to the improvement in their hygiene and manner of life, the result of the instruction they received at the sanitarium. The most important general conclusion resulting from consideration of these statistics, is the necessity of diagnosing and treating the disease in its earlier stages. Such cases are nearly always able to resume their occupation, even although the bacilli still persist in their sputa. Experience also shows that the ability to work is retained for more than four years in only about 25 per cent.

Muenchener Med. Wochenschrift, October 15.

Cause of the Hemostatic Action of Gelatin. Zibell.—In the course of considerable research, Zibell was able to establish that gelatin contains constantly about .6 per cent. of lime. The hemostatic action of lime has been long known and several of the most famous mineral waters used for hemostatic therapeutic purposes contain only .03 to .09 per cent. of lime. The anatomists have long proclaimed the mysterious relations between lime and the walls of the vessels, without attempting to explain them. In view of these facts, Zibell is inclined to attribute the hemostatic properties of gelatin to the large proportion of lime in it.

Cotton Cast for Congenital Wry-Neck. A. Schanz.—The plaster cast does not accomplish what we anticipate after operations for congenital torticollis and recurrences sometimes occur entirely due to this failure of the cast. Schanz has discarded it now completely for a cotton cast. After the sterno-cleido-mastoid muscle has been severed, the neck is packed with layers of cotton over which a bandage is wound, alternating the cotton and the bandages and gradually drawing the latter tighter, until the whole forms a cast extending from below the under lip to the axillary line, and holding the head thrown back on the median axis. Although made of soft material, this bandage completely answers the purpose of an immobilizing cast, and yet it is so elastic that it yields to the movements of the head and thorax and always fits close to them. If it becomes loosened, an outer layer can be unwrapped and tightened. The elasticity of this cast also serves to hold the stumps of the muscle far apart, as the neck is stretched to a surprising length, and the connective tissue that forms between the stumps aids in maintaining overcorrection. Schanz has applied this cotton cast in sixteen cases and has found only one drawback. This is the possible compression of the brachial plexus from pressure of the clavicle on the upper thorax. The first symptom of this compression is a numbness in the hand, and this must be guarded against by shaping the bandage to avoid the danger point. The cast is a trifle wider than the diameter of the head and curves like a watermelon below.

Value of Crede's Silver Therapy. G. Woyer.—Four or five years of experience in the Vienna University gynecologic clinic has convinced Woyer of the great value of Crede's silver therapy. He describes in detail three cases of puerperal sepsis which altered for the better immediately after inunctions of the colloid silver, and the patients recovered in such a comparatively short time that the cure can be ascribed only to the silver treatment.

Systematic Deep Breathing as a Means of Combating Seasickness. M. Kaufmann.—This communication describes the writer's personal success with systematic deep breathing as a means of preventing and arresting seasickness. He also states that he has found it very useful in cases of syncope threatening loss of consciousness or vomiting. The patient recovers much more rapidly when made to take deep inhalations. They are also useful to control epistaxis, breathing deep through the nose and expiring through the mouth. Desire to vomit can also be arrested by deep breathing; the muscles of respiration are placed in a position which is unfavorable to the act of vomiting, while the supply of oxygen diminishes the reflex irritation in the vomiting center. In singultus in nervous women, deep breathing has a similar inhibiting action on the reflex spasm. In all these applications the diverting of the attention is an important factor in the result attained. Kaufmann's experience fully confirms what Heinz claims for systematic deep breathing as a means of warding off seasickness.

Functional Test of the Kidneys Valuable in the Diagnosis for Abdominal Surgery. Casper.—The phloridzin test of the function of the kidney has been studied and perfected by Casper in respect to its value for abdominal surgery, as a means of excluding the possibility of stones in the kidney when other symptoms point to them. He described nine cases at the Naturforscher Congress in which the diagnosis of renal lithiasis seemed certain, but catheterization of the ureters separately and the results of the phloridzin test in regard to the artificially produced sugar, the proportion of nitrogen eliminated by the kidneys and the determination of the freezing-point, afforded evidence which excluded the possibility of a calculus. This method of differentiation should be reserved of course for the cases in which the diagnosis by ordinary means is dubious.

Wiener Klinische Rundschau, October 13.

Roentgen Treatment of Alopecia Areata. G. Holzknecht.—A patch of alopecia reacts to the Roentgen treatment with a persistent redness after four weeks, but the remaining hairs do not drop out, while the sound scalp reacts with the dropping out of the hairs after eight to fourteen days, but no redness. New hairs begin to grow on the alopetic patch in the successful cases in six weeks, while three months are required for the new growth of hair on the sound scalp. Certain cases prove refractory, but it seems to be impossible to determine beforehand this category of patients, although Holzknecht has been making a special study of this subject for some time. He describes and illustrates one case showing a fine growth of hair six months after Roentgen treatment was instituted. The patient was a clerk of 18. He had eight bald patches on the back of his head, the disease progressively increasing for five months when treatment was commenced. In Kienboeck's successful case published last year, the patient was 26 and the alopecia had lasted for three years and had long been stationary. Holzknecht remarks that it is absurd to attribute the curative result to the bactericidal properties of the rays. A bactericidal effect is obtained only when the rays are far too powerful to be applied to the human skin. In one case he has observed, the trichophyton tonsurans cultivated readily from a Roentgen dermatitis induced on a boy with herpes tonsurans, showing that even an unusually vigorous application of the rays had no influence to check the growth of the micro-organism.

Polyneuritis After Medicinal Doses of Fowler's Solution. J. P. Karplus.—The patient was a young woman who had taken arsenic at various times before without ill effects. Her physician prescribed the ordinary dose of Fowler's solution on account of palpitations. Symptoms of intoxication and finally the typical paralysis developed, but even then the true cause of the trouble was unrecognized for a long time. The patient was under constant medical supervision and was in a hospital for a few weeks, but the possibility of arsenical intoxication never seemed to have occurred to her advisers, although suggested by the family.

Multiple Sclerosis of Unusual Etiology. R. V. Jaksch.—Three workmen in a chemical factory were compelled to stand where their feet were very hot, and, against the rules of the establishment, they opened the doors and windows of the room in which they worked in all weathers. In the course of a few months each one presented the symptoms of multiple sclerosis of the brain and spinal cord. Jaksch attributes the affection in this case to the trauma of getting chilled while heated, which evidently occurred frequently during the cold months. Nystagmus and tremor were not observed or were transient, and there were no alterations in the papillæ. It was impossible for two of the patients to walk backward and Romberg's sign was transiently noted in one case. All the patients improved after cessation of the trauma and applica-

tion of hydrotherapy, exercises, electrotherapy and sodium iodid, so that they could partially resume work.

Influence of the Upper Intestines on the Rectal Sphincter. L. V. FRANKL-HOCHWART.—Constriction of the upper portion of the intestines induces relaxation of the sphincter, while relaxation of the intestines causes constriction of the sphincter. This law was deduced from experimental research on dogs. Nothnagel has noticed that in case of acute invagination violent tenesmus occurs. During the spastic contraction the sphincter is paralyzed and the anus becomes incontinent. Tenesmus also occurs in volvulus of the sigmoid flexure, and can be utilized as a diagnostic measure to differentiate it from internal incarceration. Both these symptoms are more easily understood if we bear in mind the relations between the movements of the intestines and the tonicity of the sphincter.

Nephrolithiasis and Affections of the Spinal Cord. H. SCHLESINGER.—Calculi have been found in the kidneys comparatively frequently in cases of traumatic injury of the spinal cord and of syringomyelia, much less frequently with spinal tumors. One case has been published in which they were found accompanying acute encephalo-myelitis. The symptoms indicating the presence of calculi do not appear until months or even years after the spinal affection. In these cases they are usually phosphatic calculi, very seldom urates. Cysto-pyelitis may be absent, notwithstanding the lithiasis and the spinal affection, but usually it accompanies phosphate stones. The spinal affection seems to have some direct or indirect influence on the formation of calculi. It may require some predisposition on the part of the subject, especially in case of urate calculi.

Cardiac Neurosis. A. PICK.—During the past year Pick has observed forty-one cases of cardiac neuroses. The symptoms were principally subjective palpitations and dyspnea following every slight physical effort, the striated muscles easily fatigued. The patients were all men betwen 18 and 30 years of age. Running for half a minute or stooping over several times would induce the symptoms, with the pulse increasing to 120 or even 140. The thyroid gland was very slightly enlarged in each case, and generally the right lobe. The syndrome continued without change for years. No aggravation has been noted in the patients seen recently after an interval of a year or two. Pick does not attempt to determine whether this syndrome is that of a latent Basedow's disease or not, but he mentions that the heart is liable to be affected even with apparently harmless struma. Schranz states that he noted degeneration of the heart in 49 out of 308 cadavers with goiter.

Tidsskrift f. d. Norske Laegefor (Christiania), October 1.

Bismuth Subsalicylate in Diarrhea. C. LUND.—Summer diarrhea and summer cholera have been invariably arrested in Lund's experience by one or two powders of bismuth subsalicylate. It should always be mixed with water in the spoon in which it is given, as it may get into the nose and cause sneezing or coughing if administered dry. He gives one gram at a time to adults and about a quarter of a gram to children. He has found it very beneficial also in controlling the diarrhea in typhoid fever.

St. Petersburg Med. Wochenschrift, October 5.

Atrophy of the Stomach Mucosa in Chronic Nephritis. W. VIERHUFF.—A woman of 60 presented symptoms of atrophy of the gastric mucous membrane secondary to chronic contracted kidney, the result of a long-standing tendency to formation of calculi. The autopsy confirmed the diagnosis. This explanation of atrophy of the gastric mucosa and its most prominent symptom, absence of secretion of hydrochloric acid, has been advanced for carcinoma, diabetes mellitus and tuberculosis, but never for nephritis to the writer's knowledge. Chronic nephritis is fully as liable as these other affections to induce the retention of toxic substances in the organism, with secondary toxic phenomena, among which atrophy of the gastric mucosa occupies a prominent place.

Gaceta Medica (Mexico), September 1.

Rarity of Appendicitis in Mexico. J. OLVERA.—The deaths from diarrhea and enteritis in the City of Mexico far outnumber those from this cause in any other large city in Europe or America. In London, for instance, the mortality from diarrhea and enteritis was 658 during the last quarter of 1899, while in the City of Mexico, with a population of less than one-third, it was 759. Notwithstanding this fact and the universal use of chile and other hot condiments, appendicitis and typhoid fever are almost unknown. The record for the last five years contains only 30 cases of appendicitis in a general mortality of 15,466 to 18,438. During this time 11 cases of typhoid fever were reported and 31 of abscesses in the iliac fossa which may have included cases of appendicitis.

Cronica Medica (Lima, Peru), August 15.

Generalized Pneumococcus Infection. E. E. ESCOMEL.—A patient with pneumonia exhibited numerous abscesses in the forearm and chest, from which the pneumococcus was derived, unassociated with other micro-organisms. Over a dozen large abscesses of this kind required evacuation, two of them in the salivary glands. Complete recovery occurred in about six weeks.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

TEXT-BOOK OF NERVOUS DISEASES, Being a Compendium for the Use of Students and Practitioners of Medicine. By Charles L. Dana, A.M., M.D., Professor of Nervous Diseases in Cornell University Medical College. Fifth Edition. With 244 Illustrations. Cloth. Pp. 633. Price, $3.50 net. New York: William Wood & Co. 1901.

THE CENTURY BOOK FOR MOTHERS. A Practical Guide in the Rearing of Healthy Children. By Leroy Milton Yale, M.D., Formerly Lecturer on the Diseases of Children at Bellevue Hospital Medical College, New York; and Gustav Pollak, Editor of "Babyhood." Cloth. Pp. 461. Price, $2.00 net. New York: The Century Co. 1901.

A MANUAL OF MEDICINE. Edited by W. H. Allchin, M.D. Lond., F.R.C.P., F.R.S. Ed., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Volume III. Diseases of the Nervous System. Cloth. Pp. 417. Price, $2.00. New York: The Macmillan Co. 1901.

INFANT-FEEDING IN ITS RELATION TO HEALTH AND DISEASE. By Louis Fischer, M.D., Visiting Physician to the Willard Parker and Reception Hospitals of New York City. Containing 52 Illustrations, with 23 Charts and Tables, Mostly Original. Second Edition. Cloth. Pp. 343. Price, $2.00. Philadelphia: F. A. Davis Co., Publishers. 1901.

A TEXT-BOOK OF PHYSIOLOGICAL CHEMISTRY For Students of Medicine and Physicians. By Charles E. Simon, M.D., Baltimore, Md. Cloth. Pp. 453. Price, $3.25. Philadelphia and New York: Lea Brothers & Co. 1901.

THE DIAGNOSIS OF NERVOUS AND MENTAL DISEASES. By Howell T. Pershing, M.Sc., M.D., Professor of Nervous and Mental Diseases in the University of Denver. Illustrated. Cloth. Pp. 223. Price, $1.25 net. Philadelphia: P. Blakiston's Son & Co. 1901.

COMPTE-RENDU DU CONGRES INTERNATIONAL POUR L'ENFANCE. Tenu à Budapest du 13 au 17 Septembre, 1899, Sous le Haut Patronage de S. Alt. Imp. et Roy. Archiduc Joseph. Rédigé avec le Concours des Présidents et Secrétaires des Sections par Etienne Scherer, Traduit en Francais par Armand Sasvari.. Publié par le Comité Exécutif du Congrès. Paper. Pp. 967. Budapest: Société Anoyme d'Imprimerie de Pest. 1901..

PROCEEDINGS OF THE PATHOLOGICAL SOCIETY of Philadelphia, October, 1901. Paper. Pp. 66. Published by the Society. 1901.

PEDIATRICS. The Hygienic and Medical Treatment of Children. By Thomas Morgan Rotch, M.D., Professor of the Diseases of Children, Harvard University. Third Edition, Rearranged and Rewritten. Illustrated by Numerous Engravings in the Text and by Colored Plates. Cloth. Pp. 1021. Price, $6.00. Philadelphia and London: J. B. Lippincott Co. 1901.

MATERIA MEDICA, PHARMACY, PHARMACOLOGY, AND THERAPEUTICS. By W. Hale White, M.D., F.R.C.P., Physician to and Lecturer on Medicine at Guy's Hospital, London. Edited by Reynold W. Wilcox, M.A., M.D., LL.D., Professor of Medicine and Therapeutics at the New York Post-Graduate Medical School. Fifth American Edition, Thoroughly Revised. Cloth. Pp. 744. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

DISEASES OF THE DIGESTIVE ORGANS In Infancy and Childhood, with Chapters on the Diet and General Management of Children, and Massage in Pediatrics. By Louis Starr, M.D., Late Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania. Third Edition; Rewritten and Enlarged. Illustrated. Cloth. Pp. 448. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1901.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE RECTUM. Being a Practical Treatise on Fistula, Piles, Fissure and Painful Ulcer, Procidentia, Polypus, Stricture, Cancer, etc. By William Allingham, F.R.C.S. Eng., Ex-Member of Council of the Royal College of Surgeons of England; and Herbert W. Allingham, F.R.C.S. Eng., Surgeon to the Household of His Majesty the King.

Seventh Edition. Cloth. Pp. 471. Price, $3.25. New York: William Wood & Co. 1901.

ESSENTIALS OF OBSTETRICS. By Charles Jewett, A.M., M.D., Sc.D., Professor of Obstetrics and Gynecology in the Long Island College Hospital. Assisted by Harold F. Jewett, M.D. Illustrated by 80 Woodcuts and 5 Colored Plates. Cloth. Pp. 386. Price, $2.25. New York and Philadelphia: Lea Brothers & Co. 1901.

THE MEDICINAL PLANTS OF THE PHILIPPINES. By T. H. Pardo De Tavera, Doctor en Medicina de la Facultad de Paris. Translated and Revised by Jerome B. Thomas, Jr., A.B., M.D., Captain and Asst.-Surgeon, U. S. V. Cloth. Pp. 269. Price, $2.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

A HANDBOOK OF DISEASES OF THE NOSE AND PHARYNX. By James B. Ball, M.D. (Lond.), Physician to the Department for Diseases of the Throat, Nose, and Ear, West London Hospital. Fourth Edition. With 61 Illustrations. Cloth. Pp. 439. Price, $2.25. New York: William Wood & Co. 1901.

SYPHILIS AND OTHER VENEREAL DISEASES. By H. De Meric, Member of the Royal College of Surgeons of England. Cloth. Price, $1.75. New York: William Wood & Co. 1901.

LESSONS ON MASSAGE. By Margaret D. Palmer, Masseure and Manager of the Massage Department of the London Hospital. Cloth. Pp. 234. Price, $2.00. New York: William Wood & Co. 1901.

THE PHYSIOLOGIC ACTION OF DRUGS. An Introduction to Practical Pharmacology. By M. S. Pembrey, A.M., M.D., Joint-Lecturer on Physiology in Guy's Hospital Medical School; and C. D. F. Phillips, M.D., LL.D., Examiner in Materia Medica and Therapeutics in the University of Aberdeen. Cloth. Pp. 99. London: Edward Arnold. 1901.

THE PHYSICIAN'S POCKET ACCOUNT BOOK, Consisting of a Manila-Bound Book of 208 Pages and a Leather Case. By J. J. Taylor, M.D. Price, $1.00 Complete. Subsequent Books to Fill the Case 40 cents Each, or 3 for $1.00. Philadelphia: Medical Council.

MICROBES AND HEALTH. By Samuel J. Wilson, M.D., Detroit, Mich., Member Clinton County Medical Society. Cloth. Pp. 230. Price, $1.00. Lansing, Mich.: Robert Smith Printing Co. 1901.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF NORTH CAROLINA. Forty-eighth Annual Meeting held at Durham, N. C., May 21, 22 and 23, 1901. Cloth. Pp. 294. Charlotte, N. C.: Queen City Printing and Paper Co. 1901.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA held at Grafton, May 22, 23 and 24, 1901. Instituted April 10, 1867. Paper. Pp. 575. Wheeling, W. Va.: West Virginia Printing Co. 1901.

PROCEEDINGS OF THE NEW YORK PATHOLOGICAL SOCIETY. May, 1901. Paper. Pp. 14. Published by the Society.

PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN. A Series of 80 Plates, Comprising more than 100 Illustrations, with Descriptive Text, and a Treatise on Cutaneous Therapeutics. Part IV. Philadelphia and London: J. B. Lippincott Co. 1901.

New Patents.

Patents of Interest to Physicians, granted Oct. 15, 22 and 29:

684,411. Surgical splint. Elihu L. Cook, Harlan, Iowa.
684,753. Vapor-bath apparatus. Palmyra O. Garrett, McGregor, Tex.
684,701. Water bag. Christian W. Melnecke, Jersey City, N. J.
685,088. Surgical appliance. Ashbel P. Barlow, St. Joseph, Mich.
685,090. Bandage or plaster. Moriz Bauer, Vienna, Austria-Hungary.
685,091. Surgical instrument case. Max W. Becton, New York City.
684,912. Pill-forming machine. Arthur Colton, Detroit, Mich.
684,978. Making food from blood. Max Dietrich, Friedrichsberg, Germany.
685,053. Antiseptic pocket cuspidor. John S. Lamond, Paterson, N. J.
685,171. Obstetrical device. Henry W. Post, Fultonville, N. Y.
11,941. Reissue. Disinfecting appliance. Thomas N. Thomson, Scranton, Pa.
35,225. Design. Body brace. Philo B. Sheldon, Erie, Pa.
35,226. Design. Abdominal bandage. Philo B. Sheldon, Erie, Pa.
685,268. Fumigating apparatus. Henry H. Freedman, Lansing, Mich.
685,538. Urine tester. Emil A. Starz, Helena, Mont.
685,543. Obtaining a preparation of the pancreas. Wilhelm Weber, Stolberg 11, Germany.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., October 24 to 30, 1901, inclusive:

Weston P. Chamberlain, lieutenant and asst.-surgeon, U. S. A., from Fort Adams, R. I., to duty at Fort Greble, R. I.

James R. Church, lieutenant and asst.-surgeon, U. S. A., relieved from duty in the Department of Cuba, to report to the Surgeon-General at Washington, D. C., for instructions.

Joseph T. Clark, captain and asst.-surgeon, U. S. A., relieved from duty in the Division of the Philippines and assigned as attending surgeon and examiner of recruits in Philadelphia, Pa.

Richard M. Fletcher, contract surgeon, member of an examining board at Fort Meade, S. D., *vice* Lieutenant Samuel M. Waterhouse, asst.-surgeon, U. S. A., relieved.

Herbert W. Hatch, contract surgeon. The journey of this surgeon from Fort St. Michael, Alaska, to San Francisco, Cal., is approved by the Secretary of War; he is assigned to temporary duty in the general hospital, Presidio of San Francisco, Cal.

Thomas G. Holmes, contract surgeon, previous orders so amended as to direct him to proceed from Detroit, Mich., to Plattsburg Barracks, N. Y., for duty at that post.

Charles E. Marrow, lieutenant and asst.-surgeon, U. S. A., from the Division of the Philippines to duty at Fort Morgan, Ala.

H. A. Santoine, contract surgeon, leave of absence granted.

Herbert M. Smith, lieutenant and asst.-surgeon, U. S. A., member of an examining board at Fort Monroe, Va., during the temporary absence of Lieut-Col. R. M. O'Reilly, deputy surgeon-general, U. S. A.

Hobert E. Warren, contract surgeon, former orders directing him to proceed from Denver, Colo., for duty at the General Hospital, Fort Bayard, N. M., revoked.

Samuel M. Waterhouse, lieutenant and asst.-surgeon, U. S. A., previous orders so amended as to assign him as transport surgeon on the transport *Grant*.

Eugene R. Whitmore, lieutenant and asst.-surgeon, U. S. A., former orders directing him to report November 1, 1901, to the President of the Faculty, Army Medical School, Washington, D. C., revoked.

Abraham D. Williams, captain and asst.-surgeon, U. S. Vol., leave of absence from the Division of the Philippines extended.

Charles E. Woodruff, major and surgeon, U. S. A., former orders revoked; he is relieved from further duty at Fort Riley, Kan., and will proceed to New York City, to report for duty on the transport *Crook* to sail on or about December 1, 1901, for Manila, P. I., where on arrival he will report for assignment in the Division of the Philippines.

Ezra Woodruff, lieut.-col. and deputy surgeon-general, U. S. A., retired from active service, having reached the age of 64 years.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending November 2, 1901.

Asst.-Surgeon R. T. Orvis, detached from the *Pensacola*, upon reporting of relief, and ordered home and to wait orders.

Asst.-Surgeon U. R. Webb, ordered to the *Pensacola*, as relief of Asst.-Surgeon R. T. Orvis.

Medical Inspector F. Rogers, having been examined by a retiring board and found incapacitated for active service on account of disability incident thereto, is retired from active service, October 28, 1901, under the provisions of section 1453, Revised Statutes.

Surgeon D. O. Lewis, detached from the *Philadelphia*, ordered home and granted sick leave for three months.

P. A. Surgeon R. T. Orvis, commissioned past assistant-surgeon from May 27, 1901.

P. A. Surgeon G. L. Angeny, commissioned past assistant-surgeon from Sept. 16, 1901.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended November 1, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 13-20, 2 cases.
Indiana: Evansville, Oct. 19-26, 7 cases.
Kentucky: Lexington, Oct. 19-26, 1 case.
Massachusetts: Cambridge, Oct. 19-26, 1 case.
Minnesota: Minneapolis, Oct. 19-26, 1 case.
New Jersey: Newark, Oct. 21-28, 15 cases, 1 death.
New York: New York, Oct. 19-26, 8 cases, 3 deaths.
North Dakota: Bottineau County, Sept. 15-Oct. 15, 10 cases; Cass County, Sept. 15-Oct. 15, 1 case; Edmond County, Sept. 15-Oct. 15, 6 cases; Mayville, Oct. 18-25, 1 case.
Pennsylvania: Norristown, Oct. 19-26, 5 cases.
Rhode Island: Newport, Oct. 19-26, 7 cases.
Wisconsin, Green Bay, Oct. 19-27, 4 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Sept. 28-Oct. 5, 3 cases, 2 deaths; Ghent, Oct. 5-12, 2 deaths.
Brazil: Rio de Janeiro, Sept. 1-15, 109 deaths.
Canada: Halifax, Oct. 5-12, 7 cases, 1 death; St. John, Oct. 19-26, 6 cases.
Colombia: Cartagena, Sept. 29-Oct. 6, 2 deaths; Panama, Oct. 14-21, 125 cases.
France: Paris, Oct. 5-12, 3 deaths.
Great Britain: London, Oct. 5-12, 175 cases, 6 deaths.
India: Bombay, Sept. 17-Oct. 1, 2 deaths; Calcutta, Sept. 14-28, 2 deaths.
Italy: Naples, Oct. 5-12, 54 cases, 5 deaths.
Mexico: City of Mexico, Oct. 6-13, 1 death.
Russia: Moscow, Sept. 28-Oct. 5, 5 cases, 1 death; Odessa, Oct. 5-12, 2 cases; St. Petersburg, Sept. 28-Oct. 12, 5 cases.

PLAGUE—UNITED STATES AND INSULAR.

California: San Francisco, Oct. 13-20, 1 case, 1 death.
Philippines: Manila, Aug. 31-Sept. 7, 6 cases, 3 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Sept. 1-15, 13 deaths.
China: Hong Kong, Sept. 7-14, 11 cases, 11 deaths.
India, Bombay, Sept. 18-Oct. 1, 454 deaths; Calcutta, Sept. 18-21, 27 deaths; Karachi, Sept. 15-22, 15 cases, 8 deaths.
Italy: Naples, Oct. 5-12, 2 cases, 2 deaths.
Turkey: Smyrna, Sept. 28, 1 case.

YELLOW FEVER.

Brazil: Rio de Janeiro, Sept. 1-15, 9 deaths.
Colombia: Bocas del Toro, Oct. 28, 1 case.
Cuba: Havana, Oct. 5-12, 1 case; Trinidad, Sept. 30, 1 case.
Mexico: Progreso, Sept. 28-Oct. 5, 1 death; Vera Cruz, Oct. 12-19, 20 cases, 7 deaths.
West Indies: Curacao, Sept. 28.-Oct. 6, 2 cases, 1 death.

CHOLERA.

India: Bombay, Sept. 17-Oct. 1, 7 deaths; Calcutta, Sept. 15-28, 19 deaths; Madras, Sept. 14-27, 99 deaths.
Japan: Yokohama, Sept. 23-30, 1 case, 1 death.
Java: Soerabaya, Aug. 1-31, 1800 cases, 1400 deaths; Samarang, Aug, 1-31, 1050 cases, 600 deaths.

THE NON-SURGICAL TREATMENT OF HETEROPHORIA.*

GEORGE M. GOULD, A.M., M.D.
PHILADELPHIA.

Had I chosen my own title I should have omitted the word "non-surgical," because in my practice I have concluded that there is no surgical treatment, properly speaking; and that any operative treatment whatever of heterophoria is not only useless but bad. For, not only does it not cure, but, in my experience, it makes real cure far more difficult, sometimes even impossible. I say, "in my experience," which is in private practice, with intelligent and co-operating patients. In hospital practice there may be rare cases in which operation is required. For six years I have seen no case of heterophoria needing operation, and none unsatisfactory when treated with common sense instead of with scissors. Of course, if the scissorer's design is to create mental effects in the patient and financial ones in both patient and doctor, that does not lie in the province of medicine, and we may look, smile, and go about our own business. But, if the object of scissoring is to lengthen or shorten a tendon, it seems to me that one will soon arrive at two or three indisputable facts: 1. In the vast majority of cases heterophoria is an innervational affair. 2. It depends upon errors of refraction. 3. Proper spectacles are the principal and effective means of cure, with the aid of prism gymnastics in exophoria. It seems unnecessary to add that it should go without saying that all other intercurrent complicating, or systemic conditions that are causative of ocular weakness and imbalance must have been diagnosticated and treated. Sometimes, certainly, such are alone responsible for the mischief. The oculist who is indifferent to or ignorant of such general causes, is not, as he should be, a physician before being a specialist. He is only one grade better than the pseudo-oculist who treats all eye-strain as due to systemic causes.

As to hyperphoria, owing to the narrowed range of muscular action of the vertical muscles some cases appear to be peripheral rather than central in origin, and with such the question would seem to be pertinent, why not tenotomize? My answer to that would be Yankee-like: Do you know a surgeon that you would trust to operate upon your own hyperphoria? I am sure that if I had ever so high a degree I would endure the evils that I had rather than fly to others I know not of. Perhaps, however, the choice would be precisely because of evils witnessed and known. For instance:

CASE 4077.—This was a professor who for a few degrees of hyperphoria had the right superior rectus "snipped" by a famous oculist, and the left eyeball was so frightened that it tried to hide under the upper lid, producing a bad effect upon the onlooker and for the patient diplopia, loss of occupation, and great wretchedness, financial, social and psychic. There seemed nothing for it but an advancement. But, before submitting he came to me. Under strict promises of secrecy not to divulge his colleague's name, who occupied a chair in the same college, I undertook the doubtful task of curing a traumatic hyperphoria of seven degrees without other surgical instruments than a couple of pieces of glass! In snipping a snip the snipper had utterly ignored a tormenting astigmatism. A partial prismatic correction added to the cylinders subsequently reduced, finally made my friend shower me with benedictions whenever we met. He does not now refer his patients to his fellow-professor!

The highest degre of hyperphoria or hypertropia I have successfully treated by refractive methods was that of:

CASE 3631.—A lawyer had 15 degrees and had been advised by a dozen or two of the best specialists to permit tenotomy. He had shrunk from following the advice although diplopia and subjective symptoms had come near wrecking his health and his business career. When he came to me, I of course found that his ametropia had been ignored or mistreated. I combined with his spherocylinders 12 degrees of prismatic correction and in a short time this was further reduced to 10 degrees. Health and happiness were completely reinstated in six months.

I do not think I have a dozen patients wearing prisms permanently for the correction of hyperphoria. Under proper ametropic correction these, like most heterophorias, disappear. It is only as regards this and the frequency of required operation that I differ from my friend, Dr. Reber, in the conclusions which he draws in the most excellent study of 150 cases of heterophoria read before this Section last year at Atlantic City. The factors of proper treatment are:

1. The absolutely accurate estimation of the refractive errors by cycloplegia and the subjective method and the prescription of spectacles and their adjustment according to the hundred modifying conditions of the individual case.

2. When the hyperphoria is 3 degrees or over, a temporary but partial neutralization by prisms may be necessary to tide over the period required by Nature to reinstate a normal balance of innervation.

3. Supplementary ocular gymnastics, mere excursions of the eyeballs upward and downward, etc., aid in bringing about balance.

4. Instruction in ocular hygiene is frequently helpful. The book or writing habitually placed too far below the horizontal plane may be productive of much eye-strain. High arm-chairs and other similar devices would vastly lessen the sufferings of many people.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

Esophoria of a symptom-producing kind, like hyperphoria, is extremely rare, is innervational, and is dependent upon ametropia. Permanently worn prisms of course only increase the disease, and tailoring the tendons is utter delusion. For example:

Case 2996.—A literary worker had both internal recti cut, reducing his esophoria of about 18 degrees to orthophoria for a month or two, but finally resulting in a reinstatement of all the old imbalance. Again the intense sleepiness came back and again the scissors were appealed to, but with precisely the same results as before. After a year of proper ametropic correction the esophoria is 6 degrees and as much happiness exists as is ever possible after the peripheral mechanism has been uselessly mangled.

Equally instructive is the case of a studious minister, who, with extreme use of the eyes at near range, has not a symptom and yet he has 20 degrees of esophoria. He requires only accurate correction of his ametropia. Hundreds of case-records show either a reduction of esophoria to a normal balance by means of ametropic correction alone, or, if not always so, there is complete absence of symptoms. Data and methods of treatment are:

1. Normal balance or physiologic orthophoria is for city-folk and near-workers, 2 degrees or 3 degrees of esophoria estimated by the Maddox-rod test, at 20 feet with suspended accommodation.

2. When there is less than 2 degrees the tendency and result is exophoric.

3. Orthophoria is almost surely a disease, likely to be worse than the higher degrees of esophoria.

4. Esophoria from 3 degrees to 6 degrees produces no symptoms with proper ametropic correction.

5. Esophoria above 6 degrees and up to the strabismic limit may or may not produce symptoms of eye-strain.

6. All esophoria is curable or at least modifiable by convergence-repression, i. e., by high corrections in hyperopia and by low corrections in myopia, but above all by proper corrections of astigmatism and anisometropia.

Exophoria, or insufficient adduction-power, is the most frequent, 50 to 1 surely, of all heterophorias, and, fortunately, the most amenable to treatment. I greatly dislike rules and laws in the practice of medicine, because there may be almost as many exceptions to almost any rule as there are instances in proof. But in a general way, I find by experience:

1. Real exophoria or insufficiency of adduction-power in a near-worker may exist and be productive of mischief when the 20-foot test shows 1 degree or 2 degrees of esophoria.

2. Orthophoria is usually exophoria, i. e., it is a disease. There is in city-dwellers, usually, an insufficient innervational power of the interni, with 20-foot balance.

3. With positive 20-foot exophoria, eye-strain and brain-tire exist in proportion to the degree of the defect.

4. Cure by prism-gymnastics is quick according to the youth of the patient, and the lowness of the degree, slow in proportion to the greater age, lessened vitality, and highness of the degree of the exophoria.

5. A not infrequent result of the prism-gymnastic treatment of exophoria is the continuance of more or less of the original exophoria as measured by the 20-foot test, but with an increase of the adduction-power five or ten, or even twenty times, there will finally come a cessation of the symptoms.

6. Having attained this high adduction-power, with relief of the symptoms, a continuance of the prism-gymnastics must be kept up occasionally with the highest power prisms, to prevent, as in any function, deterioration by disuse.

The only methods of treating exophoria of which I have any experience are:

1. Accurate estimation of the ametropia, and its correction according to the exophoria to be overcome. Low hyperopic corrections and high myopic corrections are, of course, the rule, according to the degree of the defect, but also according to the hundred of co-operating conditions, the power of accommodation, the presbyopia, the anisometropia, the age and vitality of the patient, the severity of the symptoms, the occupation, the responsiveness of reaction to prism-gymnastics, the adduction-power, etc. No finer problem or more complex one exists in medicine than this of prescribing glasses in exophoria. The prescribing optician, the "ophthalmotrician," or even the six-weeks' post-graduate specialist may not be trusted with it any more wisely than a baboon with an astronomic observatory.

2. With all fitting deference to wise advisers, I am unable to see or to imagine what least good could be accomplished by the use of so-called gymnastics with weak or low degree prisms. Attempting to jump over a thirty-foot wide stream by a two or three-foot jumper can result in little more than a deserved cold-water bath. Two or three degree helps can not meet the indications of a twenty or fifty degree weakness.

3. The gist of the matter is to increase adduction-power until it is equal to the demands. This increase of power is easily, quickly, and infallibly procurable by daily exercises with prisms, bases out, and as rapidly as the power rises, the prisms increased in degree until either the exophoria has been replaced by esophoria or the symptoms have all disappeared. Hold the power gained by occasional exercises, according to the amount of near work demanded of the eyes and also according to individual tendency to reversionary weakness. In low degrees of exophoria a frequently effective method of treatment is by what I have colloquially designated, "thumb exercises." These consist in the patient holding the thumb at arm's length on a level with the eyes and gazing fixidly at the nail while the thumb is brought accurately between the eyes as closely as is possible without any failure of the eyes to converge. The instant divergence or diplopia is detected, withdraw the hand again to arm's length, and thus continue these rhythmic exercises for several minutes, several times a day. If the increase of adduction-power and the relief of symptoms is proved insufficient, then the method of prism-gymnastics must be instituted.

4. The technic of prism-gymnastics in exophoria is: *a.* Begin with the highest degree prisms with which the images of a point of light are kept single. *b.* The prisms should be square and not round and must be accurately mounted and accurately adjusted. Holding the prisms in the hands as has been advised does harm, not good. *c.* The exercises should be ordered about four times a day, for about five minutes at a time. *d.* They should be with the object gazed at fixedly and earnestly ("with knitted brow," "savagely"). The distance of the object should be varied by an attendant, or by walking about, from 10 inches to 20 feet or more. The prisms should be raised away from the eyes and lowered about twenty-five times while gazing at differently distanced objects, during each seance. *e.* The patient

should be instructed to distinguish and guard against outward rotation of one eye with diplopia, etc.—a quickly harmful procedure. *f.* So fast as adduction-power grows, the strength of the prisms should be increased. This will usually be by 3 degrees or 5 degrees at a time, and every two or three days, until the limit is reached, esophoria induced, or the symptoms disappear. I have sometimes carried the adduction-power as high as 80 or 100 degrees before the desired result appeared. *g.* With a wished-for increase of adduction-power there is likely to be a change of ocular pressures and corneal curvatures so that a retesting of the ametropia becomes necessary.

It seems useless to take up your time with a brave array of case-histories. Hundreds, perhaps thousands, could be collated. The lessons derivable from them is all that seems necessary. The chief ones I gather from mine are as follows:

The infinite patience and clinging to hope on the part of the physiologic and neurologic ocular mechanism is a constant source of wonder and delight, and teaches the daily law to help Nature along the lines of her desires by common-sense and physiologic methods. Her motto is surely *nil desperandum,* and it should be ours. We shall rarely fail when we try to aid Nature's method of spontaneous therapeutics. We should beware of our impertinent surgical short-cuts. Surgery is the despair of medicine, and we should never adopt surgical methods while there is a glimmer of hope by natural means and in the directions indicated by the subtle and inherent strivings for normality. To show but one case illustrative of what Nature and the doctor may do when they work together let me cite:

Case 2870.—A physician's little girl of 7 came to me with 28 degrees of exophoria, i. e., her exophoria was really exotropia, the divergent strabismus being habitual except under the stimulus of the violent will to converge, when binocular vision was possible for only a few seconds. With a 3-degree prism, base out, this temporary power was impossible. I would not consent to operation. It took about four years of treatment, but to-day the child has slight esophoria, constant binocular vision, perfect acuity, and absence of all eye strain.

Even in cases of positive strabismus natural or non-surgical methods may prove effective if the patient is taken in hand sufficiently early in life, before amblyopia has become too pronounced, and before morbid habits have been too long continued.

THE OPERATIVE TREATMENT OF HETEROPHORIA.*

G. C. SAVAGE, M.D.

PROFESSOR OF OPHTHALMOLOGY, VANDERBILT UNIVERSITY.

NASHVILLE, TENN.

On what cases of heterophoria should we operate? On what muscle should the operation be done? What kind of operation should be done? These are all questions that should be answered by the operator before undertaking this class of work. Certainly, an innervational heterophoria should never be operated upon. A pseudo-esophoria is always curable by convex glasses. A pseudo-exophoria is likewise curable by concave glasses. There are cases that present themselves now and then in whom there is a want of convergence innervation, i. e., there seems to be a fault in the third conjugate innervation. This condition, as a rule, should be treated by exercise, though occasionally an operation must be done.

No operation should be done in cases of heterophoria, intrinsic in character, that can be relieved by gymnastic exercise, even though this treatment should have to be resorted to for a long while. Nor should those cases be operated upon whose muscle error is small, and for whom comfort can be obtained by the wearing of weak prisms in positions of rest.

The heterophorias not curable by correction of errors of refraction, by prisms in positions of rest, or by rhythmic exercise, should be subjected to operative procedure. Such cases are not infrequent, and the relief from operations skilfully done is by no means uncertain. There is no department of surgery that requires more care in the making of the diagnosis. The condition of every extrinsic ocular muscle must be determined before any one muscle is to be operated upon. There are but two objects in view in muscle operations, the one is altering the tension of the muscle, the other is changing its plane of action.

In order that I may be the better understood when I speak of the operation involving the changing of the muscle plane, it would be well to define it. The rotation plane of any muscle cuts the center of origin of the muscle, the center of rotation of the eye, and the center of the muscle insertion. The axis of rotation is always at right angles to this plane. The plane of an internus or an externus muscle may coincide with the horizontal plane of the eye, when, of course, the vertical axis of the eye becomes the axis of rotation. In such a condition the contraction of an internus or externus will effect only one motion, viz., the rotation of the eye directly in, by the internus, or the rotation of the eye directly out, by the externus. When the center of attachment of the internus is above the horizontal plane, no longer can the muscle plane coincide with the horizontal plane, and a contraction of the internus results in a complicated movement of the eyeball. An internus thus attached not only turns the eye in, but also turns it up and torts it in. The center of the insertion of an externus above the horizontal plane results always in a complicated movement, turning the eye out, turning it up and torting it out. When the centers of attachment of these muscles are below the horizontal plane, the secondary results of their action are the reverse of those mentioned, i. e., a too low internus turns the eye down as well as in, and torts it out; a too low externus turns the eye down as well as out, and also torts it in.

The tension of a muscle is to be altered either by a central partial tenotomy, as when operating on the too strong muscle; by shortening the muscle in the line of its original plane or by advancing it straight forward, as when operating on the too weak muscle. In making either one of these operations the existence of a cyclophoria must be first excluded. When there is cyclophoria complicating any one of the other heterophorias, the operation on the rectus muscle should alter the tension of the muscle and at the same time change the plane of its action. In such a case a partial tenotomy should not be central only, but should include those peripheral fibers, a division of which would be corrective of the cyclophoria. A shortening should be done in such a way as either to raise or depress the plane of action of the muscle as might be indicated by the complicating cyclophoria. In making advancements, the new attachment should be

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

carried either higher or lower than the original attachment, as the character of the cyclophoria might determine.

The operation to simply alter the tension of a rectus muscle with the view of lessening its power is a central partial tenotomy. This, as in all operations, should be done under strict aseptic precautions, and while the eye is under the influence of cocain. If the operation is to be bloodless, a drop or two of adrenalin chlorid solution (1 to 1000) should be instilled at the time the cocain is used. The lids having been separated sufficiently by a stop-speculum, the patient should be asked to look as far as possible in the direct opposite direction from the muscle to be operated upon, so as to expose well the field of operation. With forceps the conjunctiva alone, over the insertion of the muscle, may be raised, when a small opening should be made with a Stevens scissors. Through this opening the capsule of Tenon may be grasped and then divided. Thus the tendon of the muscle is exposed, the central fibers of which should be lifted by the forceps and then divided by means of the Stevens scissors, thus buttonholing it. While still holding the tendon up with the forceps the buttonhole may be enlarged with the scissors by cutting first in one direction and then in the other, close to the sclera, being very careful not to encroach too far toward the peripheral fibers. The forceps should now be laid aside and the Stevens hook should be inserted through the buttonhole beneath the uncut fibers, first on the one side and then on the other, by means of which the amount of resistance is determined. If this is still too great other fibers must be cut with the scissors, between the hook and the sclera, always being careful to leave a sufficient number of peripheral fibers to act as stay-cords to prevent the cut muscle from retracting too much. The strength of the uncut fibers in both directions should be equal, so that the plane of the muscle may not be changed. Both judgment and skill must be exercised, else too much or too little of the tendon may be cut. It is better to aim at leaving some of the old error uncorrected than to transform it into the opposite condition. The conjunctiva may, but the capsule of Tenon must, be divided co-extensively with the division of the tendon, to obtain the effect desired. In no kind of heterophoria should a complete tenotomy ever be done; but, if by accident it should happen, the tendon should be stitched to the sclera directly behind the original insertion, and at that distance behind determined by a correct understanding of the exact character of the error for which the operation has been undertaken.

A skilled operator will find it easy to grasp, with the forceps, conjunctiva, capsule of Tenon and tendon of muscle all at the same time, and with one snip of the scissors buttonhole all these structures and then proceed with the operation as set forth above.

If a complicating cyclophoria is to be corrected by a partial tenotomy of a rectus, not only must the tension of the muscle be altered for the correction of the main error, but its plane must be changed so as to correct the complicating cyclophoria. The kind of cyclophoria having been determined—and it is nearly always a plus cyclophoria—one is not left in doubt as to how the operation should be done. To cure a hyperphoria and a plus cyclophoria the nasal and central fibers of the superior rectus of the hyperphoric eye should be divided, while the temporal fibers should be left uncut and sufficiently strong to prevent an over-correction of the hyperphoria; or the temporal and central fibers of the inferior rectus of the cataphoric eye should be divided, leaving the nasal fibers uncut and of sufficient strength to prevent an over-correction of the error.

In a partial tenotomy for sthenic esophoria complicated with a plus cyclophoria, there being no hyperphoria, the lower and some of the central fibers of both interni should be divided, leaving the upper fibers uncut. In this way the tension of the muscle is altered, curing wholly, or in part, the esophoria, and the plane of each muscle is elevated so as to correct the plus cyclophoria. The plane of both interni having been equally elevated, there is developed, of necessity, a slight double hyperphoria, which, however, will give no trouble, being easily overcome by a pose of the head.

In operating on a case of sthenic esophoria complicated by a right hyperphoria and a plus cyclophoria, the first operation must be done on the internus of the cataphoric eye, and should consist of a complete division of the lower and central fibers, leaving uncut the upper fibers of the tendon. The threefold effect of this procedure is a correction in part, or wholly, of the esophoria, a correction of the cataphoria, and a cure of the plus cyclophoria. Whatever part of the esophoria may remain, after this operation, should be corrected by a central partial tenotomy of the right internus. Should some of the right hyperphoria remain, but no cyclophoria, a central partial tenotomy of the right superior rectus should be done; but if there should remain some uncorrected plus cyclophoria, as well as right hyperphoria, the inner and enough of the central fibers of the right superior rectus should be cut to cure these conditions. These three operations—sometimes even one or two of them—will cure a complicated case of this character.

If the esophoria is asthenic and uncomplicated, the operation of shortening should be done on one or both externi, and the plane of these muscles should be the same after, as before, the operation, otherwise a cyclophoria would be created.

If the asthenic esophoria is complicated with a right hyperphoria only, the externi should be shortened as though no complication existed, and later the hyperphoria could be treated by exercise, by a prism in position of rest for the hyperphoric eye, or by a central tenotomy of the superior rectus of the hyperphoric eye. In such a condition no muscle plane should ever be changed. The plane of a muscle should never be changed unless there is a cyclophoria to be corrected.

If the asthenic esophoria should be complicated with a plus cyclophoria alone, not only should both externi be shortened but the plane of each should be depressed so as to cure both esophoria and the plus cyclophoria. This double effect is accomplished by having the loop of the suture through the muscle near its upper margin, while the two ends are passed through the tendon near its lower margin. Tying the knot on the silver suture-plate pulls the muscle lower on the globe, thus changing its plane of action. The double cataphoria resulting will not be harmful.

If asthenic esophoria is complicated by a right hyperphoria and a plus cyclophoria, the first operation should be on the externus of the hyperphoric eye, and should be a shortening so done as, at the same time, to depress the plane of its action. The triple effect will be to cure more or less completely the esophoria, the right hyperphoria and the plus cyclophoria. If the left externus must be shortened for a remaining esophoria, whether complicated or not by a cataphoria and plus cyclophoria, one or both, for obvious reasons the plane

of this muscle should not be altered. If the plane were elevated, it would lessen the cataphoria, but would increase the plus cyclophoria; if the plane were lowered, it would decrease the plus cyclophoria, but would increase the cataphoria. After the straight-forward shortening of the externus of the cataphoric eye, whatever hyperphoria alone may exist should be treated, if sufficiently great in quantity, by a central partial tenotomy of the superior rectus of the hyperphoric eye; but if the remaining hyperphoria should be complicated with a remaining plus cyclophoria, the inner, and as much as necessary of the central, fibers of the superior rectus of the hyperphoric eye should be cut.

The operation for sthenic exophoria uncomplicated, is a central partial tenotomy of one or both externi, preferably both. The object in view being only the alteration of tension, care must be exercised that the plane of rotation shall not be changed. In operating on an externus it is far more easy to grasp, with fixation forceps, the conjunctiva, capsule of Tenon and muscle tendon, and buttonhole them with the scissors simultaneously, than it is with other muscles.

When sthenic exophoria is complicated by a hyperphoria the operation on the externi must not be done with a view of affecting the hyperphoria, hence a central partial tenotomy is indicated. Later the hyperphoria must be relieved by a central partial tenotomy of the superior rectus of the hyperphoric eye, and, if necessary, a central partial tenotomy of the inferior rectus of the cataphoric eye. The tension of these muscles should be altered without a change of plane.

In sthenic exophoria complicated by a right hyperphoria and a plus cyclophoria, the first operation should be done on the externus of the hyperphoric eye, and it should consist of a division of the upper and central fibers, leaving uncut the lower fibers. The threefold result of this operation will be: 1, relaxing the tension of the externus, lessening, if not curing, the exophoria; 2, a turning of the eye down, thus counteracting the hyperphoria; 3, torting the eye in, curing the cyclophoria. If some of the exophoria remain, whether still complicated or not by right hyperphoria and plus cyclophoria, the operation on the left externus must be a central partial tenotomy. The reason is clear: a division of the upper and central fibers would so change the muscle plane as to increase the cataphoria, although diminishing the cyclophoria; while a cutting of the lower and central fibers would so change the plane as to lessen the cataphoria but increase the plus cyclophoria. The only safe course between this Scylla and Charybdis is a central partial tenotomy of the left externus. These two operations having been done, any remaining right hyperphoria, without a plus cyclophoria, should be relieved by a central partial tenotomy of the right superior rectus; but if the remaining hyperphoria should be complicated with plus cyclophoria, the nasal and central fibers of this tendon should be cut, with the double purpose of altering the tension for the hyperphoria and changing the plane for the cyclophoria.

When sthenic exophoria is complicated by a plus cyclophoria only, the upper and central fibers of both externi (not one alone) should be cut. The triple effect of these operations is: 1, alteration of tension for the exophoria; 2, lowering the plane of both externi for the plus cyclophoria; 3, the development of a double cataphoria which, in itself, is not bad.

In asthenic exophoria uncomplicated, the tension of the externi must be increased by shortenings or advancements so done as not to change the plane of rotation. The same is true of asthenic exophoria complicated by a hyperphoria alone. Later the hyperphoria may be relieved by a central partial tenotomy of the superior rectus of the hyperphoric eye.

When an asthenic exophoria is complicated with a right hyperphoria and a plus cyclophoria, the internus of the cataphoric eye should be so shortened or advanced as to alter its tension for the exophoria, and elevate the plane for counteracting the cataphoria and curing the plus cyclophoria. If the internus of the once hyperphoric eye must be shortened or advanced to still further correct the exophoria, not any longer complicated, it must be so done as not to change its plane; and the same is true if the only remaining complication is a hyperphoria, for in counteracting the hyperphoria, a plus cyclophoria would be developed. It is also true that only the tension of the internus should be altered by a shortening or advancement when the remaining exophoria is complicated by hyperphoria and plus cyclophoria, for the reason that lowering the plane would increase the cyclophoria although lessening the hyperphoria, while elevating the plane would increase the hyperphoria although diminishing the cyclophoria. Later the hyperphoria or hypercyclophoria should be remedied by the correct operation on the superior rectus.

An asthenic exophoria complicated by a plus cyclophoria must be treated by such shortening and advancement of both interni as to alter the tension for the exophoria and elevate both planes for the plus cyclophoria. The double hyperphoria resulting would be counteracted by a pose of the head.

Cyclophoria may exist alone and may be so high in degree as to demand relief by operation. This can be accomplished by operating on both superior or both inferior recti. A plus cyclophoria uncomplicated can be relieved by dividing a few of the nasal fibers or advancing a few of the temporal fibers of both superior recti. In doing the former a double cataphoria is developed while the cyclophoria is cured; in doing the latter the cyclophoria is cured but a double hyperphoria results. Since a double cataphoria is preferable to a double hyperphoria, a division of the nasal fibers of the superior recti should always be chosen.

The plus cyclophoria can be cured by a division of the temporal fibers or an advancement of the nasal fibers of both inferior recti. The former would give a double hyperphoria while the latter would give a double cataphoria, hence, of the two, the latter should be chosen.

As to final results a division of the nasal fibers of the superior recti and an advancement of the nasal fibers of the inferior recti are precisely alike; but the former should be preferred, for it is more easily done and gives the patient much less inconvenience.

DISCUSSION ON PAPERS OF DRS. GOULD AND SAVAGE.

DR. S. D. RISLEY, Philadelphia—While I regret very much that Dr. Gould finds it necessary, under the qualifying conditions stated in his paper, to regard tenotomy of certain ocular muscles as malpractice, I find some consolation in the fact that Dr. Savage did not insist that it was malpractice to omit tenotomy. I am willing to admit that after the series of papers by Dr. Stevens, published several years ago, that the ophthalmological world ran tenotomy-mad. I heard one surgeon say that he had done more than 200 tenotomies in a single year. In one of these papers I believe we have an illustration of how the pendulum may swing too far in the opposite direction.

In 1894 in a paper I had the honor to present at Edinburgh to the International Congress, I pointed out some of the difficulties

culties that lie in the way. Attention was called to the frequent distortions to the human skull as shown in any cursory study of a hatter's forms taken as patterns from the heads of his patrons; many of which are so ill-shaped as to appear grotesque when compared with the diameters of a model skull. It is highly probable that these anomalous forms of the skull modify the form and dimensions of the bony orbit by changing the line of direction of the orbital planes. It is reasonable to suppose that during development in an anomalously shaped orbit that not only certain modifications would occur in the form of the eyeballs and in the length and line of direction of the optic nerves, but also in the origin and point of attachment, the length and direction of the ocular muscles; conditions, any one of which would lead to more or less marked disturbance of motility, and in many complex ways modify the conditions of binocular vision. In view of such considerations it is plainly obvious that any effort to reduce all the possible abnormalities of binocular vision to the simplicity of a law governing their occurrence and correction will probably result in failure. I believe, therefore, that we can not afford either in the study or management of these conditions to be dogmatic. It is my opinion that no chapter in ophthalmology is filled with more difficulties; that no subject should be approached with more critical caution than the abnormalities of binocular vision. That much harm has been done by unwisely performed tenotomies I am ready to believe; but, on the other hand, I am also sure that much suffering has been relieved and many careers rendered more hopeful by the wise aid of the skilful and cautious surgeon.

DR. M. F. WEYMANN, St. Joseph, Mo.—When a physician practices very largely in any one line, he acquires a certain amount of perfection not obtained by the average man. Thus, Dr. Savage may be able to get results above the understanding and reach of the rest. However, a measure not assimilable by the professional corps at large is a dangerous practice to advocate for general purposes, on account of the failures and actual damage in some instances that may result. Surgical interference with the muscles of the vertical plane seems to me a bad practice, although in tenotomies of the muscles of the horizontal plane I have had many nice results. Yet, even here, the complex nature of the muscular mechanism upsets often all seemingly correct and logical reasoning. A few weeks ago I operated for internal strabismus on a little girl. I decided to cut the upper fibers of the internal rectus tendon, but through some unaccountable mistake I clipped the lower portion. I was surprised to see the un-intended section produce the intended result. Likewise, I have failed when faithfully carrying out partial section according to established notions. Dr. Risley's reference to the great variability of orbital conditions also tends to show the impracticability of hard and fast rules.

DR. DUDLEY S. REYNOLDS, Louisville—There are a great many other questions to settle before proceeding to partial, or complete tenotomy in such cases. Conditions of malnutrition, state of the nervous system, habits of the individual, mode of living, age and hereditary conditions, all have to be considered. It is very important to remember what Dr. Risley has just said about physical conformation of the face and head in connection with abnormal shape of the orbit, and consequent anomalies of the orbital contents. Surely no one would expect to change the shape of the orbit by dividing the tendons of ocular muscles. Many a case of heterophoria due to anxiety and overwork, with consequent malnutrition and loss of rest has been ruined by frequent tenotomies. One recent case in my observation was operated 13 times, and the surgeon wanted to operate again, in a person with a small central scotoma in one eye. A multitude of cases of heterophoria may be cured by constitutional treatment with suitable regulation of diet, habits and mode of living. Many are cured by constitutional medication and correction of errors of refraction, without either prisms or tenotomies. Reflexes from the genito-urinary system are sometimes causes of heterophoria. I have known more than one case cured by successful operation for the cure of hemorrhoids. Many of them are due to auto-intoxication from constipation of the bowels. All these, and many more matters should be duly considered before subjecting the patient to any sort of tenotomy.

DR. J. E. COLBURN, Chicago—I must plead guilty to having performed a good many of these operations, and while I have had many occasions to regret operations I have had a great many occasions to congratulate myself and the patients upon the good results obtained. I believe with Dr. Risley that the conformation of the orbit has very much to do with the position of the eyes, their relative activity and with the production of heterophoria. I believe that errors of refraction are the cause of a great many cases of pseudo-heterophoria and also that general debility is the cause of some instances; such patients can not bear the discomforts of a muscle error with the same degree of patience they have been able to do when in a better systemic condition. I believe it is possible in a certain class of cases to accomplish many of the things Dr. Gould has referred to in his paper, but I feel that his rules must be exceedingly limited in their application. That a tenotomy, graduated or partial, is a serious operation, I am well aware, but I believe it is a justifiable procedure when done under the proper conditions. I believe in giving the patient the benefit of correcting the refraction, gymnastic exercises, etc., but that there are a certain class of cases where we must consider the patient and his inability to give us the months of time for exercises necessary to bring about the conditions which Dr. Gould says will result and that we must give such patients the relief if only for a time that comes by operation.

DR. C. H. WILLIAMS, Boston—Before we do any operations on the eye muscles, or in fact before we make a diagnosis in these complicated cases, it seems to me we need to get at all the facts of the case, as to how much muscle error there is and where it is located. I wish to call your attention for a moment to a piece of apparatus which I made last summer and which I have used for the past six months and found very helpful in this direction [exhibiting new instrument]. It consists of a hollow tin case shaped like a Geneva cross, each arm being about eighteen inches long; inside this case are a series of incandescent lights. A slot is cut in the front of each arm about half an inch wide and the length of the arm, behind which is fastened a strip of red glass. In front of this case is a wheel of wire pivoted at the intersection of the arms of the cross; this wheel carries sixteen small incandescent lights arranged in the form of a cross, to correspond to the arms of the case below. These lights are covered by having a small cylinder of tin about each lamp, and on the front of each cylinder is a number in green glass; these lights are placed on the wheel at such distances apart as would correspond to the deviation produced by a prism, when viewing the lights at a distance of twenty feet, and the number before each light gives the number of the prism which would at that distance cause a displacement of that amount. The person to be tested wears a pair of spectacles, of which one eye is filled with a red glass, and the other eye with a green glass. When testing a patient, the electric lights of the instrument are controlled by a switch so that the vertical red line and the horizontal numbers are lighted at one time, or the horizontal red line with the vertical numbers, or the vertical red line and the vertical numbers. Starting with the first combination, the vertical red line and the horizontal green numbers, the patient is asked to state where the red line seems to stand; if it comes in its true position between the 1 and 2 we know that there is no deviation of the axes of the eyes to the right or left, but if the red line seems to stand to the right (the red glass in the spectacles being before the right eye) it shows there is a convergence of the axes, and if the red line is over No. 4 it shows this deviation is equal to that produced by a prism of four degrees. If on the other hand the red line appears over No. 5 to the left, it shows there is a divergence of the axes equal to a prism of five degrees. The even numbers are to the right of the center, and the odd numbers to the left. Again, when testing a patient with the horizontal red line and the vertical green numbers showing, if he sees the red line in the center between the 1 and 2 it shows he has no

displacement of the axes up or down, but if the red line stands near the number 5 below the center it shows that the axis of that eye stands above the other equal to the displacement caused by a prism of five degrees. To show the amount of torsion, if any, the vertical red line and the vertical green numbers are lighted. If they appear superimposed, or standing parallel to each other, there is no torsion, but if the red lines and the green figures appear crossed the vertical meridians of the two eyes are not parallel, and the number of degrees which it is necessary to turn the wheel with the green figures in order to bring the red line and the green figures parallel, measures the amount of torsion. Through these spectacles the patient can only see the red lines with his right or red eye, and can only see the green figures with the left or green eye, the glasses cutting off the other rays. In this way each eye is unconsciously fixing a separate object, and if the axes of the eyes are in their proper position the red lines and green figures will seem to be in their proper place, but if there is a deviation its character and amount can be quickly and accurately measured. It is desirable to have a second pair of spectacles with the red glass in the left eye, and the green glass in the right eye; and it is essential to select the color of the spectacle glasses with care, so that the red glass will not transmit any of the green light, nor the green glass any of the red light from the lamps.

Dr. J. L. Thompson, Indianapolis—In the beginning of my thirty years' practice I paid more attention to insufficiencies of the internal muscle than to esophoria, but since I have been examining for esophoria I find that 98 out of 100 of my patients have from 1 to 3 degrees and that it seems as natural as the flexion of the hands and arms. In fact, if the patient does not have esophoria I look upon the case as an insufficiency of the internal recti muscles. I started in my practice with a great fear of operations upon the internal muscles except in cases of strabismus, where I operated freely, and it astonishes me now after twenty years to see that I have not had much over-correction in these cases. I have never operated on a case of strabismus until it has been under observation for a year, and I think in the future it will be five years before I operate on these muscle cases.

Dr. G. C. Savage, Nashville, Tenn.—Dr. Risley mentioned malformations of the skull as causative of heterophoria. There is nothing clearer than that a malformed orbit must contain an eye out of its normal relationship. The result will be one kind or another of heterophoria. In the treatment of such heterophoria, however, it is impossible to alter the shape of the orbit; therefore, if the error is to be corrected, it must be done by treatment of the muscles involved. Whatever then may be the cause of a heterophoria which is intrinsic in character, the principle of treatment remains the same. I wish to say that the instrument that Dr. Williams has very ingeniously invented will do everything that he claims for it. I do not want anybody to go from this meeting believing that I am an extremist on the muscle question, for I am not. My paper was of necessity confined to the operative treatment of heterophoria, and I am always delighted when I have a case of intrinsic heterophoria which can be cured by exercise, or by weak prisms in positions of rest. There are, however, a great many cases that can not be thus cured, and on these I always operate.

Dr. Frank Allport, Chicago—In considering the question of graduated or other tenotomies for the relief of so-called muscular asthenopia, I like not only to be honest with my patients and refrain from burdening them with unnecessary expenses, but I like also to be honest with myself. I must, therefore, ask myself the question: Do I find it necessary to perform tenotomies for asthenopia in order to secure satisfactory practical results, both to my patients and myself? A negative reply is inevitably the result of such an interrogatory. I have the average number of asthenopic patients in private and dispensary practice, and I presume I secure about the average results. At all events, in the course of a year I do not see many asthenopic patients who express much dissatisfaction from their treatment. I do not claim better results than others, and I can honestly say that I very rarely perform a tenotomy for asthenopia. Sometimes a year or so may elapse without the performance of such an operation. I therefore find it difficult to understand why some men perform this operation so frequently. I find that most of my cases do very well without tenotomies and without prisms, by a thorough correction of refractive errors and observance of the laws of health and hygiene. It may be with the unusual knowledge and skill possessed by such men as Drs. Stevens and Savage, the frequent performance of such operations may be not only useful but wise, but I am free to confess that from my own standpoint I do not feel myself capable of freely interfering with the functions of the ocular muscles. I recall the case of a gentleman operated on in Chicago who had only one eye. Through an accident his other eye was completely blinded. Some years after this accident, while suffering from asthenopia, he sought the advice of a professional muscle clipper, who, through motives which I do not attempt to analyze, performed several partial tenotomies on the good eye.

Dr. C. F. Clark, Columbus, Ohio—My experience has been very like that of the last speaker; yet I have been inclined to think of late that I have been too conservative in the matter of operations. I am willing to run the risk with being charged with radicalism when I say that within a few months a case that I had treated with muscle exercises faithfully, and for a time successfully, came to me and I found that I had kept that patient for several years with only a partial use of her eyes when she had the need for the full use of them; a very slight advancement gave me a brilliant result. By muscle exercise following the operation the abduction was carried from 18 degrees to 58 within three weeks and she had no discomfort. It convinced me that in many cases I had been guilty, as perhaps Dr. Gould has been, of being too conservative.

Dr. Hiram Woods, Baltimore—I can fully agree with Dr. Risley that if you once admit Dr. Savage's premise and then work out his conclusions you are compelled to admit that his reasoning is logical. The question with me is the premise, as given by Dr. Savage: "Heterophoria not curable by correction of refraction errors, prisms in position, or strengthening exercise." I think he should add, "provided the heterophoria is shown to be the cause of trouble still persisting." Experience has taught me that with more exact and careful methods of diagnosis the number of cases that are left for tenotomy are very small. I formerly did from ten to twenty a year, while now I do not believe I do more than one or two, and then usually for esophoria. One of the most important steps in the examination is to try to determine what the heterophoria is due to and in this connection we must not only look after the refraction and the health but into the school and home hygienic conditions. It takes a considerable amount of time to get down to these facts and possibly Dr. Thompson is right in putting it at five years. I can not go so far as Dr. Gould in saying that operation is never justifiable, for there is a class of cases in which enormous benefit results, namely, in esophoria. I do not find the high degrees of hyperphoria that some do. I have never used the instrument that Dr. Savage exhibits, but I have looked for cyclophoria persistently with the Maddox prism, as Dr. Savage taught, and found it only three or four times. In esophoria, however, with low abduction, and with the parallax displacement which Duane described, a tenotomy is often followed by the best results. I know that in my own experience a tenotomy done by Dr. Harlan of Baltimore benefited me enormously. I want to ask Dr. Gould in regard to his method of muscle exercise whether he considers the rapid development of adduction an increase in muscular strength or a development of positive relative convergence. Landolt dwells upon defective relative convergence as a cause of asthenopia. Why is it claimed that orthophoria is as bad a condition as some degrees of heterophoria? While the normal condition probably is a degree or two of esophoria for distance and three or four degrees of exophoria at the near point, as Dr. Theobald pointed out some years ago, the statement that orthophoria causes asthenopia is not in accord with my observations.

DR. L. CONNOR, Detroit—It is perfectly evident that this is a very complex problem and that some gentlemen see one part of it with greater distinctness than others. So far as my own observation goes we may seek for the cause of these muscular disturbances along perhaps three or four lines: one is a reflex occurring with certain conditions of the nose or allied organs; another is malnutrition of the eye whose muscles wobble as the muscles elsewhere do in similar conditions; a third is a physiological lack of power, and lastly there are unquestionably anatomical defects. I think it is well established that when we have settled upon an anatomical error as the cause of the trouble an operation is absolutely necessary. In other conditions the removal of the cause of irritation, etc., has certainly resulted well. It is entirely unsafe to say that anatomical conditions alone are the cause of heterophoria and that all cases should be operated upon. A friend of mine was operated on thirty-eight times within eight months and has more muscular unbalance to-day than ever before. You all know there are cases of disease of various sorts cured by operation *per se* and I am certain that many cases of heterophoria are cured simply by the cutting, and a cutting on the ear would do just as much good. I have never seen any good resulting from a partial tenotomy; I might just as well have cut the conjunctiva somewhere else. I do not mean to say the men who operate do not benefit their patients, but the good should be ascribed to its proper cause and, in some instances at least, to hypnotic influence.

DR. D. B. WYLIE, Milwaukee—The gentleman who has just had the floor touched upon a point which I think is not looked after to the extent it should be, which, in my practice at least, has appeared to be of great importance, that is, external irritation. In neither of the papers, nor in the discussion have I heard anything about correcting diseased conditions or irritated conditions of the conjunctiva. You may call these pseudo-heterophorias if you will, but they produce the same asthenopia. I have time and again seen small degrees of esophoria or exophoria disappear entirely after the cure of a very mild degree of conjunctivitis. I was somewhat surprised at one of the gentlemen stating that surgery is the despair of medicine. It seems to me that is beyond the power of any man to defend.

DR. D. M. CAMPBELL, Detroit, Mich.—The differences of opinion seem to be on the causes of heterophoria; in the treatment of the condition we are probably not so far asunder as might appear from the discussion. Most of us correct the refraction and look after the general health of the patient and cure a large number of cases, and yet in a large practice there will be a certain residual number uncured by whatever we do. In a report I made to the Michigan State Medical Society upon a study of 500 cases of asthenopia I found less than 2 per cent. that had to undergo operation.

DR. H. HARLAN, Baltimore—I envy very much the men who can have such positive convictions as to permit dogmatic statements such as we have heard. I want to ask Dr. Gould whether his statement that no case should be operated on is the swinging backward of the pendulum as the result of unsatisfactory experience in operating, or whether that has always been his opinion.

DR. GEORGE M. GOULD, Philadelphia—It is my belief that we are emphasizing entirely too much this question of muscle trouble. It may be highly scientific to do this work, but I have found many patients coming to me wearing prisms that seemed to my mind utterly unnecessary and never could have been called for. I feel it a higher duty to emphasize the importance to correct refraction, of applying the proper glasses in relation to these muscle troubles. Several misunderstandings have taken place which I wish to correct. I never said or implied that no case should be operated on. I made certain reservations and further said that this paper was written from my own experience limited to a private practice in a good class of intelligent people; I have been able to cure their symptoms or relieve them so perfectly that I have kept them as satisfied patients. I do not wish to be dogmatic because I thoroughly believe that in the matter of the practice of medicine individual genius has its own law and one man will accomplish by his method what another man could not accomplish with it.

I wish to correct a misinterpretation about "surgery being the despair of medicine." What I meant was that none of us believe in proceeding to surgical measures if we can cure our patients by medical and physiological means. We certainly despair of curing our patients naturally before we proceed to surgery. I do believe that local irritation of the conjunctiva may produce a temporary heterophoria, but on the other hand I believe these conditions are usually corrected by proper glasses which remove the heterophoria at the same time. The question has been asked why orthophoria should be considered a disease. My feeling is that in orthophoria with the Maddox rod at 20 feet there is almost always an insufficient adduction power for close work and that the trouble thus produced justifies its being considered a diseased condition.

A TABLE OF OCULAR EXTRINSIC PARALYSES.*

HORACE M. STARKEY, M.D.
CHICAGO.

In the "International Clinics," Vol. iii, Fourth Series, 1894, appeared an article by Prof. F. C. Hotz, on "The Diagnosis of Paralyses of the Ocular Muscles by the Double Image Test," which was a distinct advance in simplifying the methods of detecting the affected muscle in these perplexing cases. In studying that article, it occurred to the writer that the subject might be further simplified by exhibiting these paralyses with the position of the false image in graphic or tabular form. Soon afterward he prepared the table, which, with some modification of terms, has been used by him in teaching and in practical work since. As the table has stood the test of time and has commended itself to many practitioners and students, it is now presented for the consideration of this Section, in the hope that it may prove of value to others.

Let us consider briefly the more recent nomenclature of the movements of the eyes, mainly following that of Maddox; the muscles producing those movements, and the action of each muscle in the primary position of the eyes as well as in secondary positions.

PRIMARY POSITION.

The primary position may be stated to be that in which with the head perfectly erect, the eyes are directed toward a point upon the horizon midway between the eyes.[1]

In testing the eye muscles the primary position should be first assumed and the relations of the images formed by the two eyes studied in this position and later the relation of the images in departures from this position should be considered.

MOVEMENTS OF THE EYES.

In passing from the primary position, the eyes are capable of eight simple co-ordinate movements and, by combinations of these, all possible positions may be attained. Two of these movements, adduction and abduction, are employed in convergence and divergence: four, dextroduction, levoduction, superduction, and subduction, are employed in parallel movements; and two, extortion and intortion, are employed in rotating the eyes around their antero-posterior axis "so as to make the cornea revolve like a wheel." Because of this

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Wiirdemann.

1. While this definition is not strictly accurate for all movements of the eyes, it is sufficiently accurate for all practical purposes in making the diplopia tests.

torsion the upper segment of the cornea has been adopted empirically to represent the movements of the eye. These eight movements are produced by the twelve muscles, six for each eye as follows:

Abduction, the separation of the axes of the eyes so that the corneæ diverge, is produced by the external recti, assisted by the superior and inferior obliques.

Adduction, approximation of the axes of the eyes so that the corneæ converge, is produced by the internal recti, assisted by the superior and inferior recti.

Dextroduction, the turning of the eyes to the right, is produced by the abductors of the right eye and the adductors of the left eye.

Levoduction, the turning of the eyes to the left, is is produced by the adductors of the right eye and the abductors of the left eye.

Superduction, the turning of the eyes upward, is produced by the superior recti. assisted by the inferior obliques.

Subduction, the turning of the eyes downward, is produced by the inferior recti assisted by the superior obliques.

Extortion, the rotating of the upper segment of the cornea outward, is produced by the inferior obliques, assisted by the inferior recti.

Intortion, the rotating of the upper segment of the cornea inward, is produced by the superior obliques, assisted by the superior recti.

ACTION OF THE INDIVIDUAL EYE MUSCLES.

Each of the six muscles of the eye has one movement for which it is particularly responsible: The external rectus for abduction; the internal rectus for adduction; the superior rectus for superduction; the inferior rectus for subduction; the superior oblique for intortion, and the inferior oblique for extortion. This action of each muscle may be called its primary action, but each has other actions varying according to the position of the eyes when the action occurs, which may be called secondary. The external rectus and the internal rectus have no secondary action when moving in the horizontal line, but in all other positions they have secondary actions. All the other muscles have secondary actions in all positions. Usually the movements of the eyes in straight lines from the primary position are all that are necessary to be considered in making diplopia tests for ocular paralyses; but in certain complex cases it is desirable to study the motions of the eyes in all possible positions. The limits of this paper will not, however, permit a review of the action of each muscle in all positions.

If we keep in mind the origin and insertion of these various muscles it will assist us greatly in remembering their actions. The external and internal recti passing horizontally from origins which are to the inner side of and behind the eyeball to insertions on the horizontal meridian of the anterior segment of the globe, act. when the eye is in the horizontal plane, to simply rotate the eye to the right and left. In the upper plane each acts as a superductor and intortor, in the lower plane as a subductor and extortor.

The superior rectus from an origin which is to the inner side of and behind, passes diagonally to its insertion in the upper anterior segment of the globe near the vertical meridian. Having this diagonal position the muscle even in the primary position not only superducts the eye, but it also adducts and intorts it.

The inferior rectus having a similar origin, direction and insertion in the anterior inferior portion of the globe, primarily subducts the eye, but at the same time adducts and extorts it.

The superior oblique from a potential origin to the inner side and in front of the eye, passes diagonally to its insertion in the upper outer part of the posterior segment of the globe and in the primary position, not only intorts but also subducts and abducts.

The inferior oblique having a similar origin, direction and insertion in the outer lower part of the posterior segment extorts and also superducts and abducts.

It is thus seen that all the recti except the external adduct; that the obliques abduct; that the superior muscles, obliques and recti, intort; that the inferior muscles, obliques and recti, extort; that the superior recti and inferior obliques superduct and that the inferior recti and superior obliques subduct.

For the maintenance of binocular single vision all these muscles must act with the greatest precision and harmony, so that the rays of light coming from an object shall fall upon similar portions of the retina in each eye. If one muscle is weakened in the slightest degree the eye is not held in the proper position but rotates slightly in a direction opposite to the action of the affected muscle and rays of light falling upon a different portion of the retina from that in the other eye, the object is seen double, that is, diplopia occurs.

PROJECTION.

Observation and education have taught us when looking at an object, that is, when the eyes are so directed that rays of light coming from that object fall upon the macula, that another object so situated that rays of light coming from it fall to the left of the macula is to the right of the object viewed, and that rays of light falling below the macula come from an object above the object viewed. In the normal position of the eyes when both are accurately fixed, rays coming from the object viewed fall upon corresponding parts of the maculæ and rays coming from the right pass over to corresponding points to the left in each retina and are interpreted to the consciousness as being to the right. When, however, one eye deviates, say to the right, it is so turned that rays fall further to the right on the retina than they would if there was no deviation, and by education are interpreted by the brain, as being further to the left than they actually are. And as for all other directions, so that we find when one eye deviates from its fellow, the image of the deviating eye is always projected in a direction opposite to that in which the eye turns. It was shown above:

1. That when a muscle is weakened, the other muscles turn the eye in a direction opposite to the action of the affected muscle. 2. That projection of the false image is always in a direction opposite to the turning of the deviating eye. And from these two facts a third is apparent that is of great assistance in detecting the affected muscle, namely,

3. That the false image always appears to be displaced in the direction of the action of the affected muscle.

4. Another point of importance is the fact that the distance between the images increases when the eyes are turned in a direction calling for the action of the affected muscle, and diminished when the eyes are turned in the opposite direction.

VARIETIES OF DIPLOPIA.

According to the relative positions of the images, diplopia is classified as lateral when the images are disposed approximately horizontally and as vertical when

they are disposed approximately perpendicularly. Very rarely the displacement is about midway between horizontal and vertical; but with these rare exceptions there is no difficulty in placing the diplopia in one or the other class. These two varieties of diplopia are further subdivided according as the false image is displaced toward the temple or toward the nose. In horizontal displacements of the eye it is manifest that the false image must be displaced toward the temple or toward the nose. But in vertical displacements, owing to the fact that all the superductors and subductors are also either abductors or adductors, there is always lateral displacement and thus the false image is also projected either toward the temple or toward the nose.[2] If the images are separated so that the image of the right eye is seen on the right side and that of the left eye on the left side, the diplopia is homonymous or temporal: but if the images are crossed so that the image of the right appears to be to the left of that of the left eye the diplopia is hetoronymous, crossed or nasal. The writer much prefers the simple English terms, temporal and nasal to indicate the position of the false image, but as these have not been generally adopted the more usual homonymous and crossed are used in the table and in this paper.

A TABLE OF OCULAR PARALYSES.

Having in mind the foregoing facts, the muscle affected is readily determined. In making the tests the patient should be so placed that the eyes in the primary position are directed toward a small bright light, as a candle flame, 20 feet away. A red or green glass should be placed before one eye. This glass serves a double purpose. It makes the separate images more apparent, and it shows which image belongs to the right eye and which to the left. If now the patient sees two images of the flame, we inquire at once whether the images are side by side or one above the other. If the former, lateral diplopia, is found eight of the twelve muscles are at once excluded and we know that one of the four lateral recti muscles is involved. Knowing whether the diplopia is homonymous or crossed, the number of muscles involved is reduced to two, and then by directing the patient to turn the head to the left so that the eyes are dextroducted, or the head to the right so that the eyes are levoducted, we bring the analysis down to a single muscle and can say at once which one of the four lateral recti is involved. Suppose, for instance, that the patient says that the image of the right eye is to the right of the other and that it passes farther from it as the head is turned to the left, eyes dextroducted, we know at once that it is one of the four laterals, because the diplopia is lateral; that it is one of the externi because it is homonymous and that it is the right externus because the images separate when the eyes are turned to the right calling this musole into action.

If, however, the diplopia is vertical, we know at once that one of the eight vertical muscles is involved. If while vertical, it is homonymous, it is shown that one of the four obliques is involved. In either of these cases if diplopia is present in the upper field, that is in superduction, we know that it is one of the muscles that turns the eye up, while if present in the lower field, we know that it is one of the subductors. Having in this way reduced the quest to one of two muscles, the position of the images shows which of these two is affected. Thus if we have with the eyes turned upward the image of the right eye above and to the right of that of the left eye, the right inferior oblique is at once shown to be the one paralyzed.

Persistent diplopia indicates paralysis or paresis of one or more of the ocular muscles.[3]

1. When a muscle is paralyzed the eye turns away from the action of that muscle.

2. Projection is in the opposite direction to the deviation of the eye.

3. Projection is in the direction of the action of the affected muscle.

4. The images separate in turning the eyes in such a direction as to call for the action of the affected muscle.

DISCUSSION.

Dr. F. C. Hotz, Chicago—Several years ago I worked out a similar scheme for facilitating the diagnosis of ocular paralyses by the diplopia test. My plan was based upon the fact that we can group the six ocular muscles into three pairs, each of which controls one of the three principal rotations of the eye: the first pair (internus and externus) controls the lateral movements; the second pair (superior rectus and inferior oblique) the upward movements, and the third pair (inferior rectus and superior oblique) the downward movements. In any case of paralysis, therefore, the first question to be settled is this: The kind of diplopia locates the disturbance upon which pair of muscles? Lateral diplopia indicates an affection of the first pair; vertical diplopia in the upper field points to the second pair; and vertical diplopia in the lower field to the third pair. The next step is to decide which muscle of the pair is affected. This question is at once answered by the homonymous or crossed character of the diplopia. Homonymous diplopia of the first

2. In vertical diplopia in a patient with previous esophoria or exophoria the images might be exactly vertical (the author has seen one such case), but these exceptions to the rule must be exceedingly rare.

3. Exceptions: Injuries, diseases and tumors of the orbit causing displacement and loss of motion, usually obvious; and chronic spasms of the muscles of the eye, so rare as to be negligible.

pair points to the externus; crossed diplopia to the internus; homonymous diplopia of the second pair points to the inferior oblique; crossed diplopia to the superior rectus; homonymous diplopia of the third pair points to the superior oblique, and crossed diplopia to the inferior rectus.

The affected muscle being found it only remains to determine whether it is the muscle of the right or left eye. This last question is answered by the well-known fact that the image of the affected eye is projected in the direction of the normal action of the paralyzed muscle; and that the distance between the double images increases in this direction and diminishes in the opposite. If, for instance, we have found a paralysis of the externus and the images separate when the eyes are rotated to the left, but come together when the eyes are rotated in the opposite direction, we know at once the paralyzed muscle must be the externus of the left eye.

I have taught this method a number of years and always found the quick and easy way of making a correct diagnosis was a great revelation to the students who are accustomed to look upon the paralyses of ocular muscles as one of the most difficult and perplexing problems. Dr. Starkey has elaborated a similar method and I am pleased to learn that he too has been successful and well satisfied. It shows that students may readily understand the clinical pictures of ocular paralyses if they are presented to them in a comprehensive manner.

Dr. W. H. Wilder, Chicago—Dr. Starkey's table will be a valuable addition to the class room. It is certainly difficult to get students to comprehend this matter of ocular paralysis and any way of simplifying it is of value. The only suggestion I would make would be that this table might be supplemented by a diagram giving the evidences of tortion or tilting of images that we see when certain straight muscles or the obliques are paralyzed. I do not agree with Dr. Hotz on this point. If you have an affection of one of the straight muscles it is easily recognized without taking the patient into the dark room, but the difficulties come with the partial paralyses or pareses, where the degree of diplopia is not great and the difficulties are worse when a group of muscles are affected. It is not an easy matter to work these cases out to a satisfactory conclusion.

Dr. M. F. Weymann, St. Joseph, Mo.—The subject of the diagnosis of paralysis affecting a single muscle of the eye may be reduced to three mechanical rules whose application requires little thought and analysis: 1. Diplopia appears in the direction of the action of the affected muscle. 2. The faulty image is always in advance; this is reversed only when the paretic eye is used for fixation. The first two rules determine easily any paresis in the horizontal plane. 3. Of the muscles acting in the vertical sense, the obliques produce homonymous, the recti heteronymous diplopia.

Dr. Edward Jackson, Denver—I think it is extremely important for practical reasons not to attempt to burden the mind with any such table, but to follow a plan similar to that indicated by the last speaker. It is well enough to have such a table for reference, but I think for practical work we have the whole theory of the subject in the rules Dr. Weymann has given. The diagnosis of partial paralyses in a large majority of cases is not rendered simpler by such a scheme, and I find that they can not be settled in a few minutes or even in an hour by repeated tests. You must remember that no ocular movement is dependent upon any one muscle and no movement is lost by the paralysis of a single muscle, unless it be direct lateral movements of a certain nature. I think the measure having the greatest value as a final test is the accurate measurement of the fields of binocular fixation.

Dr. Horace M. Starkey, in reply—If I understand Dr. Hotz, this paper illustrates his method of teaching to-day as well as that of ten years ago. The object of my study has been to make the teaching of this rather complex subject as simple as possible, and certainly it has been much more easily understood by physicians and students, when explained in connection with this table, than by any other means that I have been able to devise. It is not expected that the table will be memorized, but rather to be at hand for ready reference. The reason that no supplementary table was added, as suggested by Dr. Wilder, is because it seemed to me that the simpler the table could be made the more valuable it would be.

MULES' OPERATION.*

FRANK C. TODD, M.D.

Clinical Professor of Ophthalmology and Otology, University of Minnesota; Attending Eye and Ear Surgeon to City and Asbury Hospitals.

MINNEAPOLIS, MINN.

The operation of evisceration was devised by Graefe in 1884, his object being to prevent death from meningitis following removal of suppurating globes; and by Mules of Manchester, England, at about the same time, his object being to prevent sympathetic ophthalmitis which occasionally follows enucleation. Since which time this operation has been urged by some surgeons as furnishing a more suitable stump for prothesis.

In 1885 Mr. Mules devised and executed the operation which bears his name. This consists in ordinary evisceration, including ablation of the cornea and the insertion of an artificial vitreous.

In 1886 Mr. Adams Frost of London practiced the insertion of a glass ball immediately after enucleation; his method was as follows: After incising the conjunctiva all around the cornea the tendons of the recti were secured by sutures, then enucleation followed with the insertion of the globe, after which the sutured tendons were fastened and the conjunctival flaps brought together.

Mr. Lang of Moorfields shortly afterwards modified this operation by inserting the artificial globe into Tenon's capsule.

In 1895 Dr. Fox of Philadelphia devised the operation of inserting an artificial globe into an orbit where the eyeball had previously been enucleated. His operation consists in opening the conjunctiva horizontally, dissecting a hole in the orbital tissues into which the globe is inserted, the tissues then being sutured over the ball. Dr. Fox records a success of 85 per cent. in 48 operations. Simple evisceration in the opinion of most surgeons presents no advantages over enucleation. It does not, at any rate, after a few months, make a better stump than results from a careful enucleation. In those cases where Mules' operation can not be performed, the Frost-Lang operation may be substituted. The Fox operation is a very ingenious one and certainly causes a great improvement in the appearance of appropriate cases, but it is probable that this operation will not be very generally adopted, since the reform Snellen eye has been invented and is giving such satisfaction. Many of the members of this Section have used the reform eyes, no doubt, and will give us the benefit of their experience. There are two forms made, of which I show some samples. In both of them the back is filled in, but in one it is filled in more than in the other. (Figs. 2 and 3.) They are certainly a great improvement over the old form. The large cavity which results from enucleation is partially filled in and does away, in part at least, with the collection of mucus, besides giving far better results from a cosmetic standpoint. Recently I received a letter from Dr. de Schweinitz, in which he says that by the use of the reform eye in cases where he has recently performed enucleation according to the improved

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann

technic, i. e., suturing the tendons, he has had as good results as after Mules' operation, though he states that he still performs the latter operation in selected cases. We certainly have much to thank Dr. Snellen for in giving us this great improvement, and it only seems strange that some one did not devise such an artificial eye before.* There are many cases in which the Snellen eye will be of great benefit, but I do not believe that it can ever take the place of Mules' operation where the latter can be performed, because there are at least the following advantages of the latter operation over improved enucleation with the insertion of the reform eye.

FIG. 1.

FIG. 2.

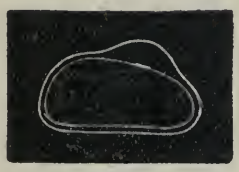

FIG. 3.

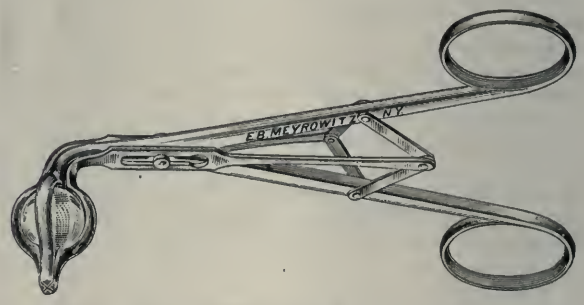
Fig. 1.—The original hollow artificial eye, or eye-shell, for cases of atrophic eye ball, and after Mules' operation. Fig. 2.—A double walled shell for cases where a smaller stump remains, as after a simple evisceration. Fig. 3.—An artificial eye-globe, where the conjunctival sac is emptied and spacious.

MULES' OPERATION.	ENUCLEATION WITH SUTURING TENDONS AND INSERTING REFORM EYE.
1. Growth of orbits uniform.	1. Growth of orbits not uniform.
2. Mobility.	2. Mobility less and will decrease in time as is the case following simple evisceration.
3. Orbit entirely filled in.	3. Orbit only partially filled in.

As yet the use of the reform eye has not been sufficient to enable us to make further comparison.



I shall mainly give you my own experience with Mules' operation and conclusions derived therefrom. If you desire a more full treatise upon this subject and also regarding other substitutes for enucleation, I refer you to the papers read before the Section of Ophthalmology of the Thirteenth International Congress of Medicine at

Mules' Glass Spheres.

Paris, and particularly to the excellent paper read at that meeting by De Schweinitz, summarizing the opinions of 67 American surgeons who had given their experience with substitutes for enucleation, 32 of whom had performed Mules' operation. It is worthy of note that those who have performed a number of these operations have had a large percentage of successes and are enthusiastic in their commendation, while many who have performed but few and had a larger percentage of failures do not consider the operation advisable. The great discrepancy in the results of the various operators surely indicates a difference in technic and I believe that statistics gathered a few years hence will show a greater percentage of successes and a larger number of operators who will agree with those of larger experience, notably Fox, Buller and Allport, who are strongly in favor of the operation. In England we find enthusiasts in Carter, Bickerton and others, who have performed the operation for many years. Swanzy says in his last edition of "Diseases of the Eye," regarding Mules' operation:

"This proceeding—a modification of the foregoing—was also proposed by Mr. Mules for cases of threatened sympathetic ophthalmitis, and, like simple evisceration, has not yet met with universal acceptance in those cases, because many fear that it does not afford sufficient protection against sympathetic ophthalmitis. I do not participate in this feeling. In cases of staphyloma, however, and in some other conditions where the questions of sympathetic ophthalmitis in the other eye, or of a new growth in the eye to be operated on, do not enter into consideration, no proceeding is, in my opinion, more satisfactory, at least in young persons, than this beautiful one of Mules'. The prothesis it gives is almost perfect

Author's Introducer.

"The danger that the glass sphere may get broken by a blow upon the eye has been put forward as an objection to this method. No doubt it is an accident which may occur, and would then necessitate the enucleation of the eye, but no case of the kind has as yet been recorded, although the operation has been in use for fifteen years. Silver spheres, instead of those of glass, have been sometimes employed to obviate the danger referred to.

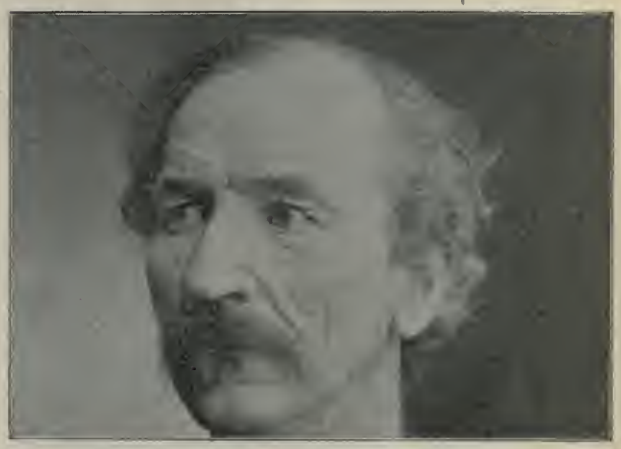
"I can heartily recommend this procedure. I use it frequently, and I am much pleased with it, for, with a well-fitting glass eye, the cosmetic result it gives is infinitely better than that produced either by complete enucleation or by evisceration of the eyeball."

De Schweinitz speaks very highly of Mules' operation and states in conclusion that "the best cosmetic results among the substitutes for enucleation, if successful abscission be excluded, are secured by Mules' operation which is only positively contraindicated by malignant disease, sympathetic ophthalmitis, extensive laceration of the sclera, and extreme phthisis bulbi." Yet he states finally: "Mules' operation, when successful, certainly furnishes admirable results, but I feel sure that although at the present time, from the cosmetic standpoint, it seems to be one of the best of the substitutes for enucleation it is not likely to endure as an operative measure, unless the percentage of failures is greatly reduced." There can be no doubt that this percentage of failures can and will be reduced.

The number of cases upon which I have performed Mules' operation are 31; these include two cases of Dr.

* Since reading this paper I have discovered an article published in the Ophthalmic Record, May, 1901, which states that the closed artificial eye was devised by J. L. Borsch, in 1894.

Allport (whom I assisted) which I have had an opportunity to follow out, also another case of Dr. Means of Columbus, whom I assisted in his first Mules' operation in 1899. All of these cases are either under my personal observation or I have recently heard from them by correspondence. Two were operated five years ago, and the others during the past four years and up to the present time. All of these patients are still retaining the globe excepting two in which the ball escaped, and the case of Dr. Means, in which the glass ball was removed eighteen months after insertion by another surgeon. These three cases are given in detail later.



Age at Operation.—The youngest person operated was one year old. and as the child had an extra large scleral cavity, having lost the eye from ophthalmia neonatorum followed by staphyloma, a good-sized glass ball was inserted in order to better assist in maintaining uniform growth of the two orbits. This child is here and I show the case to demonstrate the uniformity of orbital development. The oldest was 54 years. The only reason for not inserting a globe in old people has been the fact that

the cosmetic improvement has not been as important as in young people. The other cases ranged in age from 4 to 45 years.

Time in Hospital.—Regarding the time in the hospital, while at first I kept them in two weeks I now keep them only one week. I do not consider it essential to keep the patient in bed but a few days, and simply advise him not to use his good eye for reading and not to exercise to any extent for two weeks, though I keep the patient under observation for two weeks and prefer to see him one month. The prothesis was inserted in some cases two weeks after the operation, but in many cases it was thought best to wait a month, and in one case two months, before allowing the patient to continually wear the glass eye. Regarding the material used as an artificial vitreous I have used glass in all my cases. Fox sums up this point as follows: "I prefer first glass balls, then gold balls. Silver balls produce argyria and undergo oxidation. Aluminum globes become disintegrated, as was shown in one case where I used a perforated aluminum sphere as suggested by Dr. Bryant. This caused great pain, because the tissues surrounding it grew through the opening."

Contra-indications.—As absolute contra-indications I

would consider malignant intra-ocular growths and diseased or injured eyes which have already excited sympathetic ophthalmitis; extreme phthisis bulbi and sclera so lacerated that it could not be made to retain an artificial vitreous. (Frost-Lang operation may be substituted in the two latter classes.)

I have had no experience in performing Mules' operation where sympathetic ophthalmitis was present and have not cared to be a pioneer in the experiment, though I could not have had worse results than I have had fol-

lowing enucleation in these cases, for in the few cases I have had, enucleation failed to permanently arrest the disease, and in two cases at least total blindness ultimately resulted. Old diseased eyes, traumatic or non-traumatic, in which iridocyclitis is present and which are said to be most apt sooner or later to cause sympathetic ophthalmitis, even when sympathetic irritation is present, I do not consider contra-indications and have on my records 7 such cases; in all these cases there has been a complete and immediate subsidence of the sympathetic irritation and no return. Three years ago, however, I enucleated such an eye because the patient considered

the time element more important than cosmetics and he has since had attacks of sympathetic ophthalmitis. Had I inserted an artificial vitreous in this case I probably would have considered the operation at fault. It was simply a case in which enucleation failed to arrest a developing sympathetic ophthalmitis.

Phthisis bulbi if not extreme need not prevent the insertion of a glass globe within the sclera. Case 28 was one of phthisis bulbi. A small globe was inserted into the scleral cavity. Glaucoma is not a contra-indication if we may judge from the success attained in Case 2.

Neither do I consider suppuration of the globe a con-

tra-indication, for in all such cases the results have been highly satisfactory and suppuration has ceased with the operation. I have had four such cases, of which the worst was that of J. T. M., male, age 28, machinist. A piece of brass entered the vitreous. Mules' operation was performed ten days after the injury, the vitreous chamber was full of pus, but the tissues healed as readily as any case. The fact that the presence of tuberculosis of the iris is not necessarily a contra-indication if limited to the iris is evident from the record of Case 1. In this case Dr. Allport had performed an iridectomy for tuberculosis of the iris, and upon recurrence Mules'

operation was performed. Gunshot wounds are not contra-indications unless the sclera is too much lacerated or shot is present in the orbit and causing irritation. I have had only one such case, and in this the shot had passed completely through the ball and become embedded in the bone. Mules' operation was performed with success.

Failures would include escape of artificial globe, the development of sympathetic inflammation and a stump over which an artificial eye can not be worn because of its irritability.

Sympathetic Inflammation.—No opinion is more valuable on this point than that of De Schweinitz, who concludes after his thorough investigation of 317 operations by 32 operators, as follows: "Eyes so wounded that they are likely to excite sympathetic ophthalmitis if seen before two weeks have elapsed need not be enucleated, that is, evisceration or Mules' operation may be performed, because, *with perhaps the exception of a single case, there is no positive proof that those operations have of themselves excited sympathetic disease. They may fail to arrest the development of sympathetic ophthalmitis, just as enucleation may meet with a similar failure.*" (Italics mine.)

Dr. de Schweinitz reports painful stump requiring removal three times. The only case in which I have had

this experience is the one of Dr. Means, whom I assisted two years ago while in Columbus.

J. R., male, 22, left eye blind and at times some pain. Right eye in good condition. Mules' operation performed as usual, no reaction, recovery uneventful. From time to time Dr. Means wrote that the patient, who was away at college, complained of inability to wear an artificial eye, and at my suggestion the Doctor removed some of the stitches which he thought might be causing the irritation. May 17. Dr. Means writes in reply to my letter as follows:

"The patient you refer to has had the glass ball removed. He came to me last December and I removed another stitch that was deeply embedded in the upper fornix. I thought

probably this was causing the irritation. He returned to college, and claimed that his eye did not improve. I received a letter from him later stating that the other eye was becoming irritated. I wrote him to come to me at once, but received a letter from an oculist in his college town, saying that he had removed the glass ball to relieve irritation. He simply removed the ball and allowed the sclera to remain. The Doctor intimated that the ball was too large, and therefore made undue pressure. I have operated on only one case since, and it has proven an entire success."

I am not prepared to explain this case, but do remember that we used a ball which was quite tight and

think the explanation of the surgeon who removed the globe quite probable.

Escapes are due to the following causes: reaction, hemorrhage, sepsis and consequent sloughing of edges of the sclera, imperfect ball, too large ball, too small ball, improper coaptation of sclera, use of absorbable sutures, insufficient number of sutures, too early wearing of prothesis, and later sepsis introduced by means of the prothesis or otherwise, resulting in abscess.

Reaction.—Those of greatest experience at first had a great deal of inflammatory reaction following their operation, and Fox attributes many of his early "escapes" to this cause. In the 317 cases tabulated De Schweinitz reports excessive reaction 77 times. The only case in which I have experienced any greater reaction than following enucleation are in Cases 1 and 2; only one of these could be called excessive. These I attribute to the fact that just before inserting the globe the cavity was dried out with iodoform gauze, enough of the powder remaining to cause the inflammatory reaction, and I believe a common cause of reaction is the use of irritating antiseptics. I have found very hot sterile water of the most service, because it acts as an antiseptic, is non-irritating and effectually stops hemorrhage, which may in itself be a cause of expulsion.

Moist dressings are undesirable because they promote suppuration, and a dry, sterile or non-irritating antiseptic dressing with a pressure bandage will aid in preventing reaction. This bandage should not be removed before two or four days have elapsed, unless complications arise, and the good eye need not be bandaged at all though the patient should be cautioned to keep it quiet.

While an irritating antiseptic should be avoided as much as possible, and if used it should be followed by irrigation with hot sterile water, yet a condition of asepsis is important and the balls should be sterilized in boiling water, and before inserting should be examined to discover any small hole through which the water may have entered. Occasionally such imperfect glass globes will be discovered.

The ball inserted should be as large as the scleral cavity will admit and yet small enough so that the edges of the sclera will not be pulled apart during the healing process. Case 15, already spoken of as being the only case in which there was an escape, I believe is an example of the use of a too small ball.

Laura D., aged 4, consulted Oct. 31, 1899. Dirty wire cut left eye yesterday while at play. Find large wound across cornea with escape of contents of the globe and evidence of infection. Operation delayed till November 2, awaiting consent of mother. November 2, performed Mules' operation as usual, the only difference being that a globe was inserted smaller than the cavity would have admitted comfortably, because I had on hand no globes of medium size and could not obtain one in the city. There was no reaction and result was successful. An eye was adjusted (date not recorded) and patient returned to her home one hundred miles away. A letter was received Feb. 21, 1900, stating that on February 11 the operated eye began to "look sore," and for the next two days "she had a good deal of pain." After which there was relief, but the glass ball became visible, and February 20 it came out (three months and eighteen days after operation). My opinion of this case is that the ball being too small to become firmly encysted was movable in its cavity and acted as an irritant.

The sclerotic coat is so non-vascular that union does not quickly take place, and hence the importance of careful coaptation of the cut edges and the necessity of using many strong, non-absorbable sutures. These become encysted and do not often cause irritation, but if they should the conjunctiva can be opened and the irritating sutures removed after firm union has taken place. Occasionally it has been found necessary to suture the conjunctiva during convalescence because it had separated.

As a rule, it is best to wait a month before inserting a prothesis for permanent use, and when first used, the patient should be seen daily to ascertain the effects. The irritation produced might be sufficient to cause the recently united scleral edges to part. If this seems imminent, it may be necessary to wait a week longer, when the artificial eye may be tried again. If the sclera separates, it should be reunited with sutures as before. In my experience this has never happened.

The second case in which there was an escape of the glass ball was that of W. M., whose eye was operated upon May 28, 1898. It was an old case of recurrent iridocyclitis with sympathetic irritation. The original trouble had been gonorrheal ophthalmitis, which had occurred two and one-half years previous to the time Mules' operation was performed. The results of the operation were successful and the patient had no trouble of any consequence until May 18, 1901. While doing the ordinary work on a farm and wearing the prothesis, not taking pains to keep the prothesis clean, the tissues became infected and the result was that when he reached the city four days later I found the glass ball protruding and an abscess of the orbit present. Pus was found in the orbital tissues and in the sclera back of the glass ball. The glass ball was removed and the cavity irrigated daily. The stump is now quite healed. The escape in this case was clearly due to sepsis introduced on account of the carelessness on the part of the patient, who was constitutionally unclean.

I have always found great difficulty in securing a proper fitting glass eye to cover the stump after Mules' operation. After a successful operation the only thing required to secure perfect appearance is a well-fitting eye of the correct shade, and hence one feels like being very particular in the selection. Most of the eyes now on the market are not fitted to be used for these cases. To fit well and give the best results the iris should be placed well up and not far toward the internal side, leaving a broad white margin below while the temporal side of the eye should not be as large as the usual prothesis; an extreme convexity is undesirable as such eyes appear too prominent when in place. The customary notch should be very slight, or may be absent.

In conclusion, I wish to state that I believe Mules' operation has come to stay and that as time goes on the percentage of failures will decrease and it will be more universally performed. The following are the advantages:

1. Absence of tears and secretion.
2. Development of orbit maintained.
3. Absence of enophthalmus.
4. Moisture of prothesis maintained.
5. Mobility.
6. In general the satisfaction to the patient, because of natural appearance and consequent absence of self-consciousness, which is bound to make a vast difference in the success and happiness of the individual.

602 Nicollet Avenue.

DISCUSSION.

DR. FRANK ALLPORT, Chicago—Failures in this operation are more or less frequent from the ambitious desire to fill in the scleral sac to its utmost capacity, in order to provide a large stump upon which to place the artificial shell. Considerable reaction and swelling usually follow the operation, and if the ball is too large, stitches are liable to pull out and expulsion of the ball will follow. An important point in this operation is the use of plenty of scleral sutures. Some operators make a rule to insert three, four or five sutures. I use as many as the incised sclera will hold, and place them well back in the scleral tissue. I found it useful to follow the suggestion of Dr. Prince, of Springfield, in swabbing out the interior of the scleral sac with a 95 per cent. solution of carbolic acid just before inserting the globe, and neutralizing the acid immediately with alcohol. It certainly adds to the safety of the operation by rendering the interior of the sclera as aseptic as possible. I insert my conjunctival sutures very far back in the conjunctival tissue, as I was very much annoyed by the conjunctival sutures pulling out and leaving a central opening in the conjunctiva, thus exposing the scleral sutures. In my last few cases I have placed the sutures as far back in the conjunctiva and underlying tissue as was practically possible, and I have not since been annoyed by the unpleasant and unfortunate gaping of the edges. I always wait until hemorrhage has practically ceased before inserting the glass globe. Some operators pay little attention to this point, but the hemorrhage following the curetting of the sclera is usually excessive and while the wait is tedious, I believe it better to endure it than to be in too great haste to insert the globe. The hemorrhage can be controlled to a certain extent by the use of very hot bichlorid solutions and packings with iodoform gauze. I do not like aluminum globes, because I saw one case in the practice of a colleague in Chicago where the globe greatly disintegrated and had to be cut away with considerable disfigurement to the orbit. Up to the present time I have had unvarying success in my Mules' operations, but I am sorry to say that I have to report my first failure. It was a case in which I found a calcareous lens and orbit. When I inserted the scleral sutures in this case, I noticed that the tissue was fragile, and I should have had better judgment than to have gone ahead with the operation, but never having had an experience with an eye of this kind, I completed the operation. I subsequently lost this ball, and had to treat the case as an ordinary evisceration. I think this case should teach us the lesson never to make a Mules operation in a calcareous eye, for I believe that in such cases we will always find the sclera incapable of standing the necessary pressure.

DR. MELVILLE BLACK, Denver—Concerning the use of Snellen's eyes I believe that with their use this operation in the future will not be so frequently performed. In my experience with the Snellen eye, covering a period of two years, it has been so satisfactory that I have abandoned the Mules operation entirely and have had just as good cosmetic effects as with the implantation of the glass ball. We secure by the use of this shell all that the Mules operation can give us without the long delayed healing process, together with the fact that a large percentage of these people are unable to spend the time necessary to secure a good cosmetic result.

DR. H. FRIEDENWALD, Baltimore—I should like to make the statement that insertion of the glass globe after enucleation does not prolong the period of healing; it may after the Mules operation. I have not had experience with that. I have had only one case in which the ball came out and in that case I had used a gold one. In my short experience with the Snellen eye I am inclined to think we shall probably do these operations more rarely than we used to.

DR. H. MOULTON, Fort Smith, Ark.—One of the arguments advanced for the Mules operation is that the orbit, in the case of children, develops symmetrically with the orbit of the other eye. I have observed a number of cases in which the globe had atrophied in childhood and in every one of them the development of the orbit was very insufficient and in some the growth seemed to have absolutely ceased at the time the atrophy took place. I have wondered why operators should expect that the orbit would develop more after the Mules operation than in these atrophy cases, and I would like to ask if operators are satisfied that they have observed in practice such a development of the orbit as they expected after the Mules operation.

DR. F. C. TODD, in reply—In regard to the development of the orbit my experience has not been long enough to observe it in many cases. One of the cases just shown demonstrates the uniform development of the orbits. In that one, however, there was a large anterior staphyloma and I was able to insert a large ball, which must certainly assist in the development of the orbit. This was the one operated when one year old.

THE TREATMENT OF THE ACUTE PSYCHOSES IN PRIVATE PRACTICE.*

C. EUGENE RIGGS, A.M., M.D.
ST. PAUL, MINN.

The various forms of mental perversion usually first come under the observation of the general practitioner. As for the acute insanities, their prognosis varies in proportion to their early recognition and treatment. Skilful attention at the outset will frequently avert an attack, or, at least, cause to run a benign and favorable course that which would otherwise have developed into a prolonged and serious illness. "In regarding the causation of insanity," says Dr. Mercier, "we should not exclusively concentrate attention upon the nervous system, but should remember that this is a question of general medicine. We must not wrap ourselves up too closely in our specialty; we should take wide views, and regard insanity as a malady, not of the brain alone, but of the whole man; it is a disease of the whole organism and it can only be properly understood and properly dealt with when so regarded."

Since the representative medical schools have made a course in psychiatry an essential part of their curriculum, the attitude of the profession has radically changed with reference to insanity. It is a comparatively short time since it was thought that only a state hospital or private institution for the treatment of the insane could care for these patients. It is now believed by some of the most experienced in our profession that no person should be sent to an institution who is a suitable subject for home treatment. I am convinced, as the result of a large experience, that home care in properly selected cases (and by "home care" I mean that either in a private family or a private hospital) will shorten the length of an attack by a period varying from a few weeks to several months. There can be no question, not only that the association of the insane with each other adds greatly to their suffering, as the result of personal contact, but that auto-suggestion intensifies and prolongs indefinitely the morbid mental state. It is the absence of these conditions, together with the opportunity for individualization of treatment, which makes home care so desirable and successful.

I am far from being antagonistic to our state hospitals; on the contrary, I am most appreciative of the great work they are constantly doing. They have a defin-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

ite sphere of usefulness which they alone can fill, yet, because of their imperative limitations, there devolves upon the general practitioner great responsibilities in his unavoidable relation to the insane, which responsibilities, both in justice to his patient and himself, he can not ignore.

While it is not to be expected that the average medical man should be minutely grounded in the histology and pathology of the brain cortex, it is reasonable to demand that with the clinical aspects of mental disease he should be moderately acquainted. Neither is it required that he be able scientifically to classify his cases; this, by the most expert, can only be approximately done. All that is necessary is that he should perceive that there is a deviation from the normal mental state, appreciate the underlying causative conditions, and direct the treatment and régime indicated.

I have but little sympathy with the spirit of alienistic pessimism which has too much dominated our profession. Its probable source is the teaching of Maudsley and Lombroso. This pessimism is subversive of that greatest of all therapeutic influences, hope; it paralyzes all endeavor; its gospel is that of degeneracy; influenced by its spirit, the physician regards effort upon his part as worse than useless, and the barque of his neglected patient drifts pilotless upon a most tempestuous sea.

The distinguished English alienist, Dr. George H. Savage, once said to me that if he believed as Dr. Maudsley did, he could not practice his profession. His experience did not substantiate Maudsley's conclusions. He had observed children of an insane mother or of an insane father, even of parents, both of whom were insane at the time of conception; he had kept these under observation for years, and they had never departed from the normal.

No one will deny that the innate resistance of the cortical cell in these cases is not up to the average, but there is, beyond question, an inherent tendency upon the part of the nervous system to revert to the normal, and if circumstances and environment permit, the brain cell will, in the process of time, regain its initial power.

The recognition of this inherent lack of resistance in the cell, and the prevention of special stress at such critical periods as adolescence, the climacteric and senescence, together with the buttressing of the nervous strength at all times, will prevent the nervous system from exceeding its "tensile resistance," and the life of the individual will not vary noticeably from that of his fellow. Upon the family physician devolves the supreme duty of recognizing tendency, checking it by environment, and preventing its becoming inevitable. In other words, his chiefest duty is that of prevention rather than cure.

I am aware that if inherent nervous defects go beyond a certain limit (and where this mystic boundary lies no one can say) degeneracy and death are inevitable, Nature declaring that that racial stock is no longer fit to exist. These inevitable degenerates bear but a small proportion to the entire social unit, yet their number has been greatly increased by the ignoring of the principles which I have just laid down. The necessity for the early recognition of the first deviation from the normal can not be too strongly emphasized, the standard of comparison being the individual himself. One must not overlook the normal physiologic variations which become pathologic only when they extend beyond their natural boundaries.

Persistent insomnia, digestive disturbances associated with constipation, loss of weight with a lowering of the general physical tone, inertia, abnormal elation or depression, should be regarded with grave suspicion in persons predisposed to mental alienation.

Dr. Mercier regards toxemia as the sole cause of insanity. According to his view, hereditary tendency means simply "a defective power of elimination, rather than textural defect." This surely seems too dogmatic. I believe rather that Dr. Clouston's theory, that insanity is due to perverted nutrition of the cortical cell, is correct. So-called hereditary tendency simply means that the cell metabolism is more unstable than normal. It may be stress and heredity, or it may be toxemia, with or without heredity, which gives rise to the perverted brain functioning.

The general practitioner is familiar with the mental features characteristic of toxic states, such as Bright's disease, diabetes, the fevers, pneumonia, the puerperal, post-operative and post-influenzal insanities, also those of the poisons—chloral, opium, alcohol, cocain, etc. He well knows that the insanity is toxic, and chemistry and bacteriology teach him not only its origin, but the most approved method of treatment as well.

An impoverished nutrition in one having the insane diathesis does not necessarily mean insanity; it may result in one of the neuroses, such as neurasthenia, hysteria, chorea, epilepsy. Given inherent nervous defect, the pathologic resultant may be either a neurosis or a psychosis. Perverted cellular nutrition is the basic cause of the pathological findings in insanity, such as morbid changes in the cell itself, increase of the neuroglia, degeneration of the blood vessels, and the pathological changes of the membranes, the skull and the scalp. The fundamental fact, then, which we have to consider is that of cell nutrition. Prevention of the metabolic derangement is the one thing of supreme importance. This is much easier of accomplishment in its beginning than after the complete evolution of the disease; it is for this reason I have placed so much stress upon the importance of the early recognition and treatment of mental diseases.

Physicians disagree as to the importance of rest in the treatment of the psychoses. Some uniformly keep their patients in bed; others as uniformly insist upon exercise: either method used indiscriminately is pernicious. Treatment should be individualized and the method adapted to the needs of the case, not the case to the method. The value of rest in the care of the acute insane can not be too strongly insisted upon. Perverted metabolism will remain uncorrected so long as the patient is allowed to over-fatigue himself. While functioning is excessive, cellular nutrition is impossible: the nerve cell is unable to repair in the intervals of functioning the loss sustained during the period of overactivity. In mental disorders restitution upon the part of the higher cortical elements is imperfect, and forced rest prevents abnormal activity, placing the neurons under the physiological conditions most favorable for their nutrition. Moreover, it is far from improbable that nerve cells suffering from altered metabolism generate toxins which greatly intensify the abnormal condition.

Nutrition is of the greatest importance in the acute insanities, which are, as a rule, underfed. Milk and eggs are the best nourishment. I recall an instance last year where the patient had grown steadily worse on an ordinary diet. After coming under my care I gave her as high as 140 ounces of milk, three or four eggnogs, six tablespoonfuls of bovinin, together with six ounces of

malt, daily. Her recovery was satisfactory. Full feeding is especially important in puerperal cases; it will quiet patients when hypnotics and sedatives prove utterly useless. I do not believe in temporizing. If the patient refuses food, or takes it in insufficient quantities, I always resort to artificial feeding. Some months ago I had under my care a most violent case of recurrent mania; it was the third attack, and after previous seizures death had seemed imminent from exhaustion. During this attack this was absolutely averted by the immediate and persistent use of the stomach tube until she took sufficient nourishment voluntarily.

The digestion of these large quantities of food is materially assisted by massage. The secretions can not be too carefully watched. Colonic flushings with the normal saline solution are most useful in overcoming sluggishness of the bowels. While food is the best hematinic, a good iron preparation is usually advisable; strychnia is admirably adapted both to quiet excitement during the acute stage and to assist convalescence. Whisky also is especially valuable in controlling excitement; strychnia and whisky are more efficient for this purpose than is hyoscin. I have found paraldehyde, sulfonal and trional to be the best hypnotics; but the possibility of hematoporphyrinuria must be borne in mind when the two latter agents are used. I think, however, the less hypnotics are used, the better; in my experience the hot pack and the hot bath have proven more efficacious. Mechanical restraint, although seldom necessary, is at times desirable. I have had wildly excited cases ask for it, and they were certainly much quieter and less irritable when placed in the restraining sheet than when controlled by the nurses alone.

It is hardly necessary to say that a nurse, experienced in mental diseases, is very essential to the successful handling of these cases. The personal interest of the nurse in the patient counts for much in the betterment of the case; her cheery presence is a constant inspiration, while by keen insight and unfailing tactfulness she can do much to correct the mental obliquity. Observant of the likes and dislikes of her patient, she may so shape the environment as to avoid unnecessary irritating influences; with a gentle persistence she may direct along healthy channels the morbid energizing. The discovery and cultivation of some special preference or capability on the part of the patient may furnish a clew which will lead to recovery. Some years ago one of my cases of acute mania apparently ceased to improve after reaching a certain point; chronicity seemed imminent. The nurse observed that the patient possessed not a little taste and skill in botanizing. We succeeded in interesting her in the flora about St. Paul; as her interest in this work increased, her delusions disappeared.

I wish especially to emphasize the danger from suicide during convalescence; it occurs as frequently as during the acute attack. Too great care can not be taken to avoid such an unfortunate contingency.

Under certain conditions and in carefully selected cases travel is a therapeutic measure of great importance. To advise it indiscriminately is more than a mistake; it is a crime. Whether it be by sea or by land, the special nature of each case must determine. My own observation and experience coincide with the views set forth by Dr. Savage in a recent article on "The Use and Abuse of Travel," the salient points of which I here give: The purpose of travel, namely, to aid the nutritive processes, to prevent introspection, and to healthfully modify the association of ideas, must ever be kept in mind. Travel has two spheres of greatest usefulness, either as a preventive measure or as an aid to convalescence.

Slight dementia, due to serious bodily illness, and the insanities associated with phthisis, asthma, etc., have been greatly benefited by sea voyages. Paranoia is harmed, never helped; travel increases the morbid egoism and intensifies the delusions. In excited mental cases, especially in general paralysis, travel is contraindicated. Much has been hoped for it in adolescent insanity, but the results have been most disappointing. An ocean voyage is thought to be especially desirable for the milder melancholias, those arising from shock, influenza and overwork. The graver forms of the disease are only intensified by it. A case of melancholia of the pronounced religious type, now under my care, has developed melancholic frenzy as a result of being kept too constantly on the move; the quieter melancholiacs are kept, the better. Travel greatly increases the probability of suicide in this class of cases. "I think," says Dr. Savage, " the person who makes the melancholiac rush from dissipation to dissipation, is a brute, an ignorant brute."

DISCUSSION.

DR. RICHARD DEWEY, Wauwatosa, Wis.—The experience which I have had has been that the general practitioner very seldom considers for a moment the possibility of looking after a case of acute psychosis personally or at the home of the patient. Sometimes I have seen patients who might well have been cared for in their own homes sent away to institutions, and yet I think the other mistake is more apt to be made, namely, that of keeping patients who need special care and skill and experience under conditions in their own homes or in general hospitals that are unfavorable to them. The man who has had experience with this class of patients can sometimes give them excellent care, even at home, but generally speaking, the home treatment is apt to fail. According to my experience, the physician who has not had an opportunity to come in contact for a prolonged period with insane patients in institutions for the insane, is apt to fail in appreciating the interests of the case. Not infrequently he fails to take proper precautions to prevent the patient from committing suicide, or he may require more of the patient than the conditions of the case will admit or are desirable in the way of exercise. Such patients are also decidedly apt to be kept too much under narcotics, particularly if demonstrative or noisy. The question of travel, to which Dr. Riggs referred in his paper, is another point in regard to these cases that requires careful consideration. In the incipient stages of the acute psychoses, or during the period of convalescence, travel may prove beneficial, but in the acute stage, especially in those forms of psychosis in which there is depression, there is so much self-concentration that these patients are incapable of taking any interest in travel or of deriving any benefit therefrom, while they obviously incur certain dangers.

DR. JOHN PUNTON, Kansas City—I am a firm believer in the theory that in the treatment of all forms of acute psychosis very little can be done towards a cure without proper and absolute isolation, whether at home or away from home. One of the great drawbacks I have to contend with in the treatment of this class of cases is to keep the patient free from all outside influences, especially the friends and relatives. A great many general practitioners can not realize the importance of this measure, and in referring the case they try to make all sorts of compromises with you, and tell you that they will turn the patient over to you providing you permit the friends and relatives to visit him when they please. I think the lesson ought to be taught to the general practitioner that at times absolute isolation is necessary. Sometimes resort to absolute isolation, however, is not imperative, but the majority of cases require it within certain limits. One of the great difficulties in connection with the acute psychoses is their early diagnosis. Very few practitioners are qualified to make

a diagnosis of an acute psychosis in the early stage of the disease. Very few general practitioners are fully awake to the fact that upon what is done during the first three months of an acute insanity largely depends the chances of recovery. These cases rapidly pass from a curable to an incurable stage. I do not regard a general city hospital as a proper place for cases of acute insanity, nor do I think that such patients should be kept in asylums. I think the more sane we can make his surroundings, the better for the patient.

Dr. Frank P. Norbury, Jacksonville, Ill.—From the standpoint of the general practitioner, we can look upon many of the problems of the acute psychoses as belonging to internal medicine, and I look upon acute cases, especially in adolescents, as chiefly in that field of problems. Not infrequently these patients are suffering from malnutrition, due to overstudy, loss of sleep, faulty feeding or defective elimination; anemia is pronounced, and, if this and other conditions of innervation are recognized and taken hold of at the proper time and in the proper way, I am quite sure that much can be done for these unfortunates without the necessity of waiting for the development of insanity and then resorting to its routine treatment. The general practitioner should fall in line with the alienist in the treatment of the acute psychoses and the alienist must be a well-grounded, thorough internalist. I know full well, both from my experience in the hospital and as a consultant out of it, that the general practitioner is too apt to put all these cases in one class, and, ere he resorts to an inquiry as to what are the problems involved, he is too willing to resort to the use of sedatives and hypnotics. We who are working in internal medicine as well as giving special attention to mental diseases, are loth to regard insanity in general, leaving out the question of heredity, as involving anything more than great problems of internal medicine.

Dr. C. A. Drew, State Farm, Mass.—It seems to me that the general practitioner, when he treats these cases at home, is obliged, because of the surroundings of the patient, to resort to the use of drugs which he knows are not, perhaps, for the best interests of his patient. He has many difficulties to contend with that the physicians in institutions have not. The problem is largely one of internal medicine, and it is often necessary to get the patient away from his immediate friends and family. Their overanxious state is detrimental to the patient's welfare and interferes with the treatment. As regards the treatment of a case of acute psychosis, elimination is of the first importance, and this is best obtained by the use of cathartics, Turkish baths and cold sponging. The patient should be removed from his immediate family and at least two good nurses should be provided to take care of him; in cases of delirium, three nurses are not too many. One suggestion made by the essayist should be accepted with some hesitation, namely, the use of alcoholic stimulants. Most cases have an underlying neurasthenic constitution, and we might do them great injury by stimulating them with alcohol at this stage. Indeed, alcohol is rarely, if ever, indicated in acute psychoses of patients under 50 years of age. In the involution psychalgia of an older patient, its anesthetic effect may be grateful and less objectionable than that of opium. I can not endorse too heartily the recommendations as to early, forced feeding, and the use of strychnin as a stimulant when stimulation is needed. This, after the torpid bowel has been thoroughly unloaded, is among the most important precepts of mental therapeutics. Substituting the Turkish bath or the wet pack for alcoholics, when a sedative is needed, I could heartily agree with every proposition and conclusion of Dr. Riggs' paper.

Dr. Orpheus Everts, Cincinnati—So far as Dr. Rigg's views of the subject presented are hypothetical, they are as good as any. So far as they are practical, I endorse them fully.

Dr. J. G. Biller, Cherokee, Iowa—I have had considerable experience in the treatment of insane people at home, and the results have always been disastrous. If patients were removed from home when insanity first manifests itself, a large proportion of them would be better off. In my section of the country most of the people are farmers, and, although many of them are intelligent as regards the ordinary affairs of life, they are not intelligent when it comes to taking care of a crazy person. Their sympathies are too apt to run away with them. The patient will receive better attention and his chances of recovery will be better in a well kept institution for the insane, even though trained nurses can be provided for his treatment at home.

Dr. F. W. Langdon, Cincinnati—It has been my fortune to be obliged to treat many cases of the acute psychoses outside of institutions for the insane, and I have seen a fair proportion of these cases terminate favorably. Yet, we should remember that the environment in which the abnormal mental state developed is not the best in which to recover from it. Many of the mental aberrations consist of distorted associations, and they can not be treated satisfactorily in the accustomed surroundings. In exceptional cases they may be treated successfully at home, but even then the wisdom of this course is doubtful. Most of these patients are poor and the expense of skilled attendance is more than the average family can bear for any length of time. Such patients can be better taken care of and for less money at a private institution. However, there are many places aside of the patient's home and the regulation institution for the insane where these patients can be successfully and satisfactorily treated. I refer to small convalescent homes or a farm where in a private family the patient's environment can be completely changed. If "non-institutional" treatment were substituted in this paper for "home" treatment I should agree with the conclusions.

Dr. M. P. Sexton, Kansas City—It is entirely impracticable to treat a case of acute psychosis at the patient's home. Even where they have the means to do everything that is necessary, it is impossible for the family to turn the patient over to the doctor and nurses. There are certain home influences which will prevent the doctor from carrying out his views. I believe, therefore, that everyone of these cases, unless the illness is exceedingly brief, should be sent away from home and placed in an institution where the medical man is constantly on the ground and in absolute control, and where every one connected with the institution is trained for his or her work.

Dr. F. Savary Pearce, Philadelphia—I wish to indorse what Dr. Riggs has said as to the practical advantages of forcing the patient to take nourishment. I have in mind a patient, a young woman suffering from hebephrenia, who was apparently drifting into permanent dementia. She refused to take nourishment of her own accord and resort was had to forced feeding. By means of the stomach-tube, large quantities of milk were introduced into the patient's stomach daily, and she immediately began to improve and is perfectly well to-day. It is a singular fact in these cases that if you persist the patient will finally acquiesce in the method of treatment even though refusing to swallow from a glass. The patient to whom I have referred would not take any food of her own will, but, as soon as the nurse produced the stomach-tube, she would open her mouth and allow it to be introduced. In my opinion, forced feeding is as important as the environment.

Dr. Harold N. Moyer, Chicago—In the management of a case of acute psychosis, it is not always possible to do the ideal thing. We are frequently forced, by the circumstances of this or that particular case, to temporize, and we often lay down rules one day, only to break them the next. This, at least, has been my experience. I have in mind a case of acute psychosis that recovered after a course of treatment at home and in travel extending over a period of about two years. The expense of his treatment was between $30,000 and $40,000. There was no time during his illness that removal to an institution would not have proved beneficial, and he would probably have recovered there at least six months sooner; the main thing with the friends, however, seemed to be to avoid commitment to an institution.

Dr. H. A. Tomlinson, St. Peter, Minn.—I want to call attention to a statement made in the paper which might lead to misapprehension. The persistence of the idea that it is harmful for the insane to be associated together is contrary to the

experience of those who are most familiar with their care. Within the past year this subject was discussed in two papers by prominent German alienists, both of whom stated that in their experience recent cases of insanity are best cared for in dormitories, and that their association together is an advantage, because it gives the patient something besides himself to think about. This has also been my personal experience. Any case of acute insanity can be treated successfully outside of an institution, but I agree with the statement made by Dr. Langdon that no insane person can be cared for so well nor cured so promptly while living under the conditions in which the mental disturbance developed. There should be not only an entire change in environment, but also the removal of every one connected with the life of the patient at the time of the outbreak of the mental disturbance. For these reasons, unless circumstances are exceptional, any given case of insanity will recover in an institution properly equipped for its care more quickly than the same patient will in a general hospital or a private house.

DR. JAMES G. KIERNAN, Chicago—I have had considerable experience in the treatment of acute psychoses, both as a hospital physician and as a neurologist outside of the hospital. In dealing with such a case, various elements, to some of which Dr. Moyer referred, must be taken into consideration. In a large number of cases of confusional insanity, it does not make much difference whether they are treated at home or in an institution, but it does make a difference whether or not a commitment should be made out. Commitment in most of the states is attended by disgraceful publicity and it leaves a certain stigma. The mental confusion states can be advantageously treated in sanitariums and in general hospitals. Home treatment of these cases, however, is exceedingly trying on relatives, and more than one member of the family may break down from the care of such cases. Neither neurasthenia nor hysteria can be properly cared for in the home environment, and such patients must be removed from home ere much can be done for them. This is true to an even greater extent of the psychoses. Melancholia, for example, should never be taken care of at home. The environment has a bad effect and suicide is always an imminent possibility. Wealth can not guard against this when they are taken care of at home. The home care of acute psychoses is harmful rather than beneficial, and is an important factor in the increase of the insane; under home conditions the insane but too frequently pass from an acute to a chronic state. The influence of the chronic insane on the acute insane has for decades been shown to be beneficial. In this, Krapelin but repeats the experience of alienists the world over, and this position has almost become a truism among alienists. The influence of the chronic insane upon the acutely insane of the explosive type is peculiarly beneficial. It conduces to an amount of self-control by them not otherwise attainable. The objections charged to the association of the acute and chronic insane arise from the disgraceful overcrowding of the insane hospitals for the benefit of the localities in which they are built. Such overcrowding prevents individual treatment and supervision, the absence of which has for decades proven very injurious.

DR. C. E. RIGGS, St. Paul, in reply—I believe that the distinction that has existed between the neurologist and the alienist is a thing of the past. As practicing physicians, we have to deal with both of these conditions, and as the result of my experience, I have formed definite conclusions on the subject, and these I have given you in my paper. I have had patients plead with me never to send them back to state institutions. I am not decrying the institutions themselves, but the disagreeable associations connected with them. We all know the effect of suggestion, whether upon the sane or insane, and I am firmly convinced that the suggestion of the chronic insane upon the acute cases is harmful and undoubtedly prolongs the condition which we are trying to correct. I use the term "home care" in a modified sense. I fully recognize the advantages which have been referred to, and in many instances we must accommodate ourselves to the particular circumstances of the case. The stigma that attaches to this condition in the eyes of some people undoubtedly is one of the factors which induces the family or friends to try to keep the patient at home. One of the objects of my paper was to call attention to the incipient manifestations of the trouble, and its relations to the problems of internal medicine. The use of alcoholic stimulants in these cases is only advisable in certain instances. I have seen whiskey used with beneficial effect in these cases; if necessary, it should be given freely, practically *ad libitum*, until the desired result is attained, but not longer. I recognize the dangers referred to, but I have never seen any unfavorable results follow its use after the recovery of the patient.

THE PSYCHOSES OF CHOREA.*

HAROLD N. MOYER, M.D.

CHICAGO.

Our nosology fails to distinguish between chorea which occurs as a symptom in the course of an infection, which by some is regarded as a rheumatism, and that which is dependent upon organic disease. The acute chorea which has more or less involvement of the joints and pericardium, and sometimes without it, is commonly spoken of as the chorea of Sydenham. The agent is not the same in all of the cases. The choreas which are associated with mental disease in adults, generally have an organic basis; the secondary dementia accompanying post-hemiplegic chorea, and Huntington's chorea, are due to progressive degeneration of the cerebral cortex, associated with dementia. Many of the insane present choreic movements, which are simply the expression of organic changes in the cortex, occurring in the terminal states of the ordinary psychoses.

Excluding the choreas of advanced life usually associated with organic disease, the occurrence of a well-marked psychosis in the progress of the chorea of Sydenham is exceptional. The case which is reported in this paper is the only one that has come under my observation.

The mental condition of the choreic child is one on which there is no unanimity of opinion. Spitzka[1], prompted by a sensational claim made in the New York Neurological Society that all choreic children are morally imbecile, says: "In mild cases of chorea the mind is no more seriously affected than in any other affection annoying to children and associated with insomnia. Even in severe cases, the mental faculties may be found to be quite intact. Such disturbance as is found in the majority of cases, is the result of the motor disturbances and of the ensuing restlessness, irritability and peevishness of the child. In protracted cases of chorea, the mind suffers in the direction of actual insanity; in that case, maniacal outbreaks, confused delirium, enfeeblement of the memory, rapid emotional change, and, in extreme cases, dementia may ensue." A psychosis with these symptoms is to be designated as choreic insanity.

Regis[2] gives a much better picture of the mental condition of choreics. He calls attention to their defects of memory and attention, the mobility of ideas, the lack of consistency in the recollections and the mental hebetude. The most characteristic symptom in these patients is the existence of special hallucinations to which Marce especially called attention. These almost always involve vision; very rarely, taste, hearing or common sensation. They are especially common in females and rarely appear before 14 years of age. They occur chiefly

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

in the evening, in the drowsy condition between waking and sleeping, and are very often continued in dreams. They are always of a painful nature, terrifying and fantastic, and abound in scenes of deaths, burials, obituaries and conflicts. They cause so much terror that the patient is in fear of going to sleep and will try to keep himself awake in consequence. When these hallucinations are continued into the sleep, they cause nightmares. This symptom is sometimes a premonitory sign, occurring many days prior to the convulsive movements. Sometimes, and more commonly, it appears at the time the choreic paroxysms show themselves. Its early disappearance is a favorable sign; sometimes it becomes continuous and deepens into an actual insanity. The majority of choreic patients are impressionable, emotional, disputative, and even violent.

This picture of Regis of the mental condition of the choreic accords with my own experience. Of the last ten cases which I have seen of the chorea of Sydenham, occurring after 10 years of age, four presented in well-marked degree, the changes which Regis describes. In four others the history was so imperfect that such mental phenomena might easily have escaped detection. The remaining two were surrounded by people who were sufficiently intelligent to describe such a condition had it existed; so its absence may be reasonably predicated.

My own judgment of the mental condition of choreics inclines more to that of Regis than of Spitzka, though it is to be remembered that the latter describes the peevishness and irritability which goes to show that he does not regard the mental condition of the choreic as quite normal. He does not, however, refer to the specific hallucinatory stage preceding or accompanying the choreic manifestations, which was pointed out by Marce, and which my observations show is frequently present.

Regis, in speaking of choreic insanity proper, says that it may be either maniacal or melancholic. Certainly the former is the most frequent, as I have not met with it in my own experience, nor have I seen a well-marked case of melancholia or seen a report of it described in the literature. Meyer[3] in discussing choreic insanity, says that no one can doubt that derangement of the mental functions in acute chorea is very common. He regards the maniacal form as the most frequent, but also recognizes the agitated melancholic type, and even an acute delirium, occurring in this disease. In chorea he recognizes two types: those in which the insanity precedes by some time the chorea and those in which it comes on some time after the chorea. He describes the case of a girl of 8 having marked mental depression, with a tendency to remain in the same position. Once or twice a day she became, without any external cause, suddenly excited; she scolded, broke what was within her reach, and struck at those who went near her. All hallucinations were denied, a statement which was repeated after her recovery. Three or four days after commencement of this state, choreic movements were noted, at first slight, but later becoming general. At the end of six weeks' treatment, the choreic symptoms had entirely subsided and with them the mental derangement.

My own patient was that of a fairly well-developed girl, 15 years of age, without neurotic heredity—at least so far as could be gathered from an imperfect family history. In the spring of 1900 she developed choreic movements fairly well marked in the upper extremities, which later became general. In the third week she became acutely maniacal, restless, sleepless, singing, constantly dancing about, knocking against the furniture and other objects until the skin became excoriated and bruised in many places. Sleep was impaired and her nutrition rapidly failed. Under treatment, which included rest in bed, there was a gradual lessening in the choreic movements and a complete recovery from the chorea and with it a disappearance of the mental symptoms. In the spring of the present year the chorea returned and with it the acute maniacal conditions. The symptoms presented were identical with those of the preceding attack. A few cases of acute insanity in the course of the chorea of Sydenham have been reported of recent years.

Bode[4] described a case in a woman 24 years of age who, five weeks before coming under observation, had given birth to a child. The mental symptoms were melancholic in type. The chorea and insanity lasted a month and a half, and during its progress she developed an optic neuritis, which improved under treatment. In this case the symptoms point to organic disease, probably a luetic trouble.

Jastrowitz[5] reports the case of a girl 20 years of age who developed a mental trouble in which there was depression having the general appearance of a primary dementia. During the progress of this affection, chorea developed with the ordinary accompaniments of pain in the joints. Later, the chorea disappeared, but without very marked improvement in the mental condition. A second case reported by the same writer is much the same in its clinical history, excepting that there was improvement in the mental condition and the chorea, though there remained a loss of memory for the period of the illness and an impaired recollection of happenings prior to the illness.

Cowen[6] reports a case of maniacal chorea in a man 21 years of age in which the chorea developed some time after the onset of the psychosis. There was complete recovery from both the chorea and the mental disease, but with a loss of memory of occurrences during the period of the illness.

Reifensthul[7] describes two cases of chorea minor which were accompanied by marked mental symptoms, the character of which is not stated.

C. W. Burr[8] reports a mixed case in which chorea and acute delirium occurred in the course of scarlet fever.

It will be seen that the rarity of reference in the literature shows that insanity in the course of Sydenham's chorea is exceptional. My own case is one of the most typical so far described in the literature. Many of the cases reported are evidently associated with organic disease of the nervous system, acute febrile affections, or pregnancy, in such a way that the direct relation of the psychosis to the chorea is obscure.

The following conclusions are justified by our present knowledge of the subject:

1. A well-marked alteration of the character and mentality can be noted in the majority of cases of chorea, usually preceding by some weeks the onset of the choreic movements.

2. Distinct hallucinatory phenomena are present in a considerable number of cases, which are not, however, of sufficient severity to merit being classed as a distinct psychosis.

3. The mental disturbance in chorea usually comes on after choreic movements, but it may precede them.

4. The type is usually maniacal, though it may occasionally be melancholic or present the character of an acute delirium.

5. Mental disturbances are commoner in older children; they are rarely observed before the twelfth year.

6. Choreas which are accompanied by mental disturbance later in life, are almost always accompanied by organic changes in the central nervous system.

7. The prognosis is favorable when the mental disease complicates the simple, acute chorea of Sydenham. Insanity associated with chorea in middle and advanced life is almost invariably associated with organic disease of the central nervous system.

DISCUSSION.

DR. C. EUGENE RIGGS, St. Paul—I saw two cases of chorea associated with insanity last winter. I found the literature very barren upon this phase of chorea, and was interested in the phenomena these cases presented. In both of them the mental condition followed the chorea. One was a colored girl, about 15 years old; the other was a young man, about 17. The girl was apathetic; she would not talk, could be induced to take nourishment only with the greatest difficulty, and had spells of intense excitement, when she had to be restrained. The young man was rational at intervals, with periods of excitement, and he showed a suicidal tendency. He made a perfect recovery. The last time I saw the young woman her condition was unchanged, but I think she will recover.

DR. E. G. CARPENTER, Columbus—I have observed perhaps half a dozen cases of insanity combined with chorea in the adult. Two of the cases were Huntingdon's chorea. Four of the cases resulted fatally. It is safe to look upon insanity following Huntingdon's chorea in the adult as a grave condition. In the cases which I observed, the patients gradually grew worse and died within two or three years. The choreic movements became very active and led to exhaustion.

DR. EDWARD E. MAYER, Pittsburg—I have been interested during the past year in the psychoses of chorea on account of two cases which were under my care. One was a case of mania following childbirth, which had been preceded by choreic manifestations. The other case, which I saw recently, was a woman who is still under treatment. She suffers from chorea accompanied by mental depression. The chorea came on immediately after the menopause, which was about two years ago, and about six months later she developed symptoms of mental depression, which have resisted various methods of treatment and have steadily progressed, until now she presents the typical picture of hypochondriac melancholia. I can not entirely agree with the statement made by Dr. Moyer that we fail to differentiate the chorea which represents an infection and that which is a symptom of some known organic disease.

DR. JOHN PUNTON, KANSAS CITY—While the literature upon this subject is rather scanty, I do not think these cases are so very rare. About six years ago I had a case of acute mania, of a very violent form, coming on during the course of a chorea. The patient made a good recovery in four or five months. Since then she has remained entirely well, and has married.

Foreign Bodies in the Rectum Among the Convicts in French Guiana.—Clarac writes from the penal station in Guiana to the *Annales d'Hygiène et de Méd. Coloniale* that the convicts secrete money, saws, files, etc., in their rectum to conceal them until an opportunity for escape arrives. They put the articles in a small cylindrical metal box and manipulate the box close to the sigmoid flexure. The symptoms of proctitis, etc., which are induced by this foreign body attract attention to the patient, and the box can usually be palpated.

MIRROR-WRITING AND THE INVERTED IMAGE.*

ALBERT B. HALE, M.D.

Assistant Clinical Professor of Ophthalmology at Rush Medical College (University of Chicago).

AND

SYDNEY KUH, M.D.

Assistant Clinical Professor of Neurology at Rush Medical College (University of Chicago).

CHICAGO.

The retina receives an inverted image of objects as they are related in the outer world. That this is so is proven by all text-books of optics[1] and accepted by all text-books of physiology.[2] But the fact that we do perceive objects in their normal relations, although equally undisputed, has been the subject of many theories, both fanciful and serious, since the modern scientific world has been dominated by inductive philosophy. One of the earliest explanations was that of retinal function by which the retina itself projects in a certain direction only the image received upon it, and is connected by one particular nerve fiber with the brain in such a way that the brain connection of the upper retinal element lies below, that of the lower above, that of the right to the left and of the left to the right, so that the image is reinverted on the cortex of the brain. This theory can be received neither by the physiologist nor by the psychologist, for we know that the nerve connections are by no means so simple as this implies, and that the visual process itself is so complex that it must be developed by education before it becomes the perfected function which enables us to localize in space.

A second explanation is that of cerebral function, which to the metaphysical psychologist is an act complete in itself and not amenable to any further analysis. Physiological psychology, however, demands that the cerebral process be analyzed into its component factors. And in doing so we learn that the visual act is by no means so simple as it would appear. In fact, any similar psychic act is complicated. "We may," says Binet in his "Psychology of Reasoning,"[3] "consider external perception as a synthetic operation, since it results in the uniting of the information actually furnished by the senses to the information furnished by preceding experiences. Perception is a combination of the present with the past. To perceive a body which is actually in the field of vision, to recognize in it a certain form, size, position in space, certain qualities, etc., is to unite in a single act of consciousness actual elements (that is to say, the optical sensations of the eye) and past elements (that is to say, a crowd of images); it is to make a single body out of these unconnected elements. This is a phenomenon which completely escapes consciousness; by consulting that witness alone, the operation of perceiving an object appears to be an easy and natural act which demands no effort of reflection on our part; that is in reality an illusion. Experiment and reasoning prove to us that in all perception there is work." Meynert, in his essay entitled[4] "Zusammenwirken der Gehirntheile," gives expression to identical views. We must necessarily, therefore, consider the apperception of the image as a very complex process, into which perception, association and co-ordination enter.

It is not, however, within the province of this article to discuss in greater detail the phenomena of vision; they are at best nothing but a receptive psychic process. Be-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

tween this and any productive manifestation of our visual act lie the equally complicated psychomotor acts. There are innumerable motor acts which depend for their stimulus upon vision: if we see a falling body we jump to one side, since we have learned that that is the way to avoid danger. In a more deliberative way, when we reach for anything we extend the arm in that certain direction in which experience tells us the object lies. If we wish to reproduce anything by writing we accomplish this by combining visual impressions with psychomotor and motor processes. It is this combination which interests us here particularly.

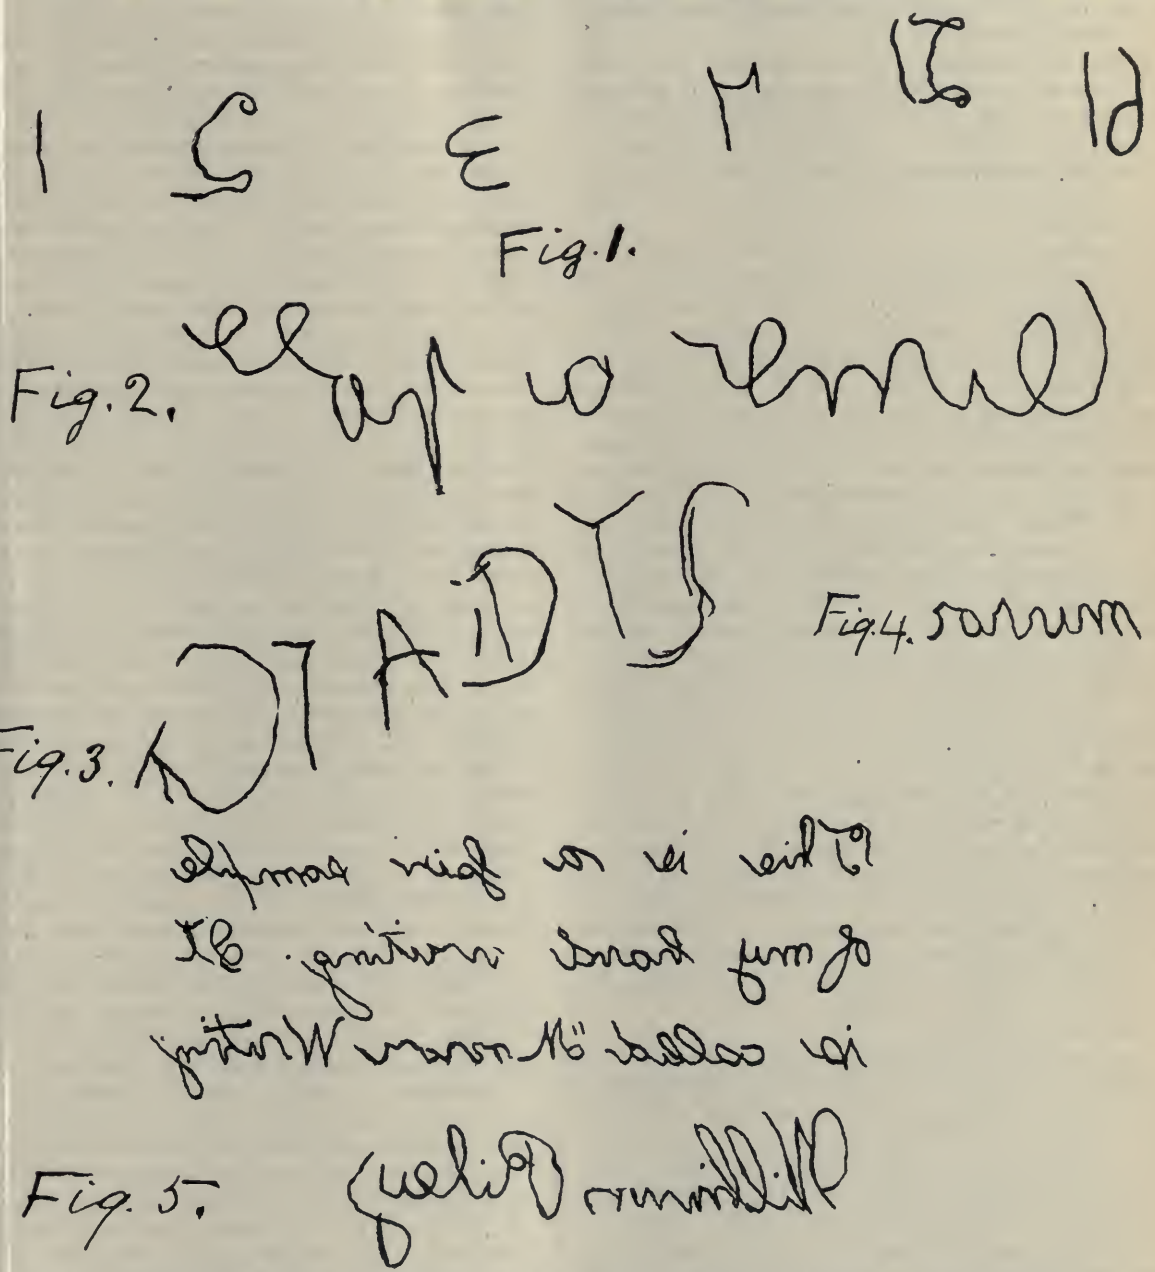

Fig. 1.—Spontaneous writing of numerals (1, 2, 3, 7, 21, 16). Boy, righthanded, 5 years, 6 months.
Fig. 2.—Spontaneous mirror-writing. Boy, righthanded, 6 years, 2 months.
Fig. 3.—Spontaneous name-writing. Girl, 5 years.
Fig. 4.—Mirror-writing. Girl, 13 years. (St. Paul Medical Journal, 1900, p. 386.)
Fig. 5.—Mirror-writing. High-grade male imbecile, 13 years. (From Mills: Journal Nervous and Mental Diseases, 1894.)

Hitherto writing has been studied in its motor rather than in its psychic aspects, and this is especially true of that pathological condition resulting from defective cerebral activity, mirror-writing. Almost all of those who have written upon this subject during the last twenty-two years have been influenced to a greater or lesser extent by the theory of Erlenmeyer, who gave a purely mechanical explanation for the occurrence of mirror-writing in those whose right side is paralyzed. So strong has been this influence that but very few of these writers have even mentioned the occurrence of mirror-writing in righthanded, healthy persons. Erlenmeyer, in his monograph entitled "Die Schrift,"[5] starts out with the statement that abduction (from the body) is the natural method of executing all finer movements, consequently also of writing. His corollary to this is "that righthandedness is the result of writing with the right hand, and the greater development of the left cerebral hemisphere the result of righthandedness, not its cause." Consequently that those who wrote from right to left must have been lefthanded. In support of this he quotes from the ancient Jewish Thalmud to the effect

that writing on certain religious scrolls must be done with the right hand, but that when there is a lack of such scrolls the use of those written with the left hand was to be permitted. A translation which we have had made by a competent scholar shows, however, that this does not mean that the ancient Jews were lefthanded, but that writing with the left hand, though allowed, was still, as with us, an exceptional condition. While Baelz,[6] who resides in Japan, in reviewing Erlenmeyer, proves that many of his statements about right and lefthanded writing are utterly false.

A further elaboration of the theory just mentioned applies it to mirror-writing by asserting that when in consequence of some lesion to the left hemisphere the right hand is made useless, the left hand must necessarily follow this general impulse toward abduction and in writing pass from right to left and produce what we call mirror-writing.

Many authors, although supporting Erlenmeyer's theory by numerous illustrations, incidentally mention a certain degree of mental weakness as an essential factor in producing mirror-writing, and assert that in lefthanded children of a certain age mental defect without hemiplegia may be sufficient to cause mirror-writing. Among righthanded feeble-minded children who were asked to write with the left hand, a relatively large number produced mirror-writing. An attempt to examine writing done by such children with the right hand has never been made upon a larger scale, but there are some few isolated observations which show that under these conditions also mirror-writing may be produced. Such a case has been reported by Sweeny in the *St. Paul Medical Journal*.[7] Of the occurrence of mirror-writing done with the right hand and by mentally normal children we have found records of only two instances in literature; the one is that of Preyer's child, who in his "Die Seele des Kindes"[8] states the following: "That my child when in his early years he was asked to write the ordinary numerals, as I showed them to him, to my surprise copied in mirror-writing most of them, especially the 1 and the 4, the last frequently also inverted, the 5 on the other hand always correctly; this is not, of course, due to an error in vision, but to an incorrect transposition of the visual image in those motor images which are necessary for writing. Other boys acted—I was informed—the same. The distinction between right and left caused me difficulties in my own childhood, which even now I remember distinctly."

A second similar observation is that recorded by Dr. Albert B. Hale in the *Ophthalmic Record* for May, 1900,[9] which led to the investigations here reported. But that it does occur, and that very commonly, in intelligent, normal, righthanded children, there can be no doubt. Discussion with many teachers in kindergartens and with intelligent mothers has shown us that children in their earliest years, when they have not yet been taught systematically to write, but are stirred with the imitative impulse characteristic of the young, do write in mirror-writing with their right hand, not always, but quite frequently, and with less and less frequency as education advances and observation becomes more exact. We have a number of examples to illustrate this fact, most of them produced by children of between four and a half and seven years, and it will not be difficult for any one to obtain such an example from a child of the proper age if, with patience, he submits the child to a series of tests. It must be noticed that these specimens are not copies by the child, but are purely spontaneous productions by the child's hand of the image he had in his mind. It is not possible to express in figures the frequency with which this phenomenon occurs, owing to the very fact that it must be spontaneous; because to ask a certain number of children on a certain day to produce certain results would be to destroy the proper time and spirit, since these can be secured only occasionally. But we have no hesitancy in saying that almost every child at a certain period of its development will be found to produce spontaneous mirror-writing, and that, too, with its right hand.

The question may well be asked here, to what do these facts lead? Or is it possible to connect all the different conditions under which mirror-writing is produced with the phenomena of visual apperception? Hitherto we have discussed only the psychomotor and motor expressions of vision as we find it in the child, and these facts seem to offer no satisfactory explanation for the relationship between the inverted retinal image and writing. If, however, it were possible to place the brain of an adult, trained in psychological observation, in the position of the child, and if we could then study the effect of this new retinal image upon motor expression, and could find that, after all, tactile sensation adjusts itself to visual sensation by association, then we might hope to approach the solution of the problem. Fortunately, such experimental proof has been furnished by Professor George M. Stratton, who, in a number of papers, gives the results of experiments on "Vision Without Inversion of the Retinal Image."[10] This as stated is a paradox, for while in the case of the child we have discussed the normal inverted image, Professor Stratton has by means of lenses produced in himself an upright retinal image. But on careful consideration it will be seen that the adult mind by experience has acquired the habit of associating his tactile sensations with his natural visual sensations, and as it is impossible to dispossess him of these tactile sensations, it is necessary to give him a new retinal image so that this association may be disturbed and, relatively speaking, made to become as they were primitively. To be sure, the new condition is not identical with that in the child, and never can be, because the adult has a large number of memories from which to draw, while the child must both acquire memories and learn to use them. But the experiments of Professor Stratton have temporarily demanded that he form a large number of new associations, in order to co-ordinate his visual, tactile and other sensations. It is impossible to quote at any length from Professor Stratton's most interesting papers; they must be read in full to judge of their convincing character. We must here be satisfied with referring you to these papers in the *Psychological Review* for November, 1896, July and September, 1897, and in *Mind*, viii, New Series, No. 32, and to the discussion in the report of the Third International Congress for Psychology in Munich, 1897. They show that under these unnatural conditions the knowledge of spatial relations was reacquired under more or less difficulty and that our perception of the field as upright is not dependent upon the inversion of the retinal image. He very soon learned the distinction between the new above and below, but found that "right and left were felt to be by far the most persistently troublesome relation, when it came to translating visual into tactual or motor localization," an experience which agrees beautifully with that of Preyer quoted above. He furthermore found that "the inverted position of the retinal image is, therefore, not essential to upright vision." An experience with which we are all familiar demonstrating the correctness of this view, is found in our everyday use of the mirror. We dress ourselves, we

adjust our neckties with the transposed image without difficulty, because these simple acts have become habits, but as soon as we attempt an unusual performance with the aid of the mirror, we become awkward and find it difficult to distinguish right from left, and forward from backward, while we readily differentiate the above from the below.

To sum up, our knowledge of spatial relations does not depend solely upon the perceptive organ, but is rather a complicated process of mental co-ordination. The retinal image remains the same, but our mental image of it is guided by our experience acquired laboriously through the other senses. The doctrine of Binet receives one more confirmation.

Let us now recapitulate under what conditions mirror-writing has been observed. We have already dwelt long enough upon that phenomenon which we may call normal mirror-writing and which, as we have shown, is a frequent occurrence in righthanded healthy children of a certain age. Into this group belong those instances mentioned by Durand[11] of mirror-writing produced by adults possessed of little intelligence and who seldom write. Such cases are of common occurrence, and most of you have undoubtedly seen signs crudely painted by the uncultured in which one or more letters or numerals, the S and N particularly, were reversed.

As a pathological condition mirror-writing produced with the left hand is rather common in children with impaired intelligence (see references 12 to 19 inclusive), deaf mutes (references 20, 21, 22), the blind,[22] and in cases of katatonia.[23] No investigations as to results obtainable with the right hand were made in any of these conditions except in the case of Sweeny, mentioned above. Furthermore, mirror-writing done with the left hand has been seen in those who, through some brain lesion, have lost the use of their right arm, and in some few instances when through accident to the right arm itself this member became useless.[24] Both in feeble-minded children and in hemiplegic adults the fact has been noted again and again that coincidently with improvement with the mental condition the tendency to produce mirror-writing decreased.

The question here presents itself, What mental and physical condition have all of these cases in common? Of the existing two theories neither one gives an explanation which will satisfactorily cover all of the cases just mentioned. Erlenmeyer's purely mechanical theory, besides being based upon incorrect data, does not in any way throw light upon those very frequent cases in which individuals do mirror-writing with the right hand. While it can not be denied entirely that the well-established habit of writing in abduction movement with the right hand may have some influence upon the production of mirror-writing with the left hand, still this influence can not possibly be very powerful, or otherwise mirror-writing in hemiplegics would be the rule rather than the exception.

Ireland's theory[25] is even less satisfactory. He believes "that in the case of paralysis of the right arm the image or impression or change in the brain tissue from which the letters are produced by the hand was destroyed, and that in trying to write with the left hand the patient wrote from an image on the right side of the brain in every way corresponding save that it was reversed. Thus D on the left side would have ⊏ on the right, written from left to right with the right hand, or from right to left with the left hand." Modern physiological psychology can not accept with such completeness the dual character of the brain. Then the first objection could be made to this theory also, it does not cover all cases. Credit must be given Ireland, however, for introducing into the process some consideration of the visual element.

Mirror-writing is not a pathological effect per se, nor is it confined to the mentally defective. It is found in the youngest of children and disappears with greater rapidity among the normally intelligent than among the feeble-minded, until at last with but few exceptions it is found only among the mentally defective or in those with some organic brain lesion. Buchwald,[26] Preyer,[8] and Treitel[21] all admit that the condition is not essentially pathologic, and we agree with the last named when he states that Soltmann[27] goes too far when he sees in mirror-writing "the mirror of a diseased mind."

The link that unites all the various states in which mirror-writing shows itself must be an imperfectly developed or pathologically disturbed psychic association and co-ordination. Imperfectly developed in the very young, and in some of the mentally defective, pathologically disturbed after hemiplegia, and in certain acquired psychic disturbances, among which katatonia must be mentioned, the psychosis in which "idea association is nullified."[23]

Why, then, it will be asked, if the inverted retinal image is such an important factor, is it simply mirror-writing and not a complete inversion of the reproduced character? An answer is found in the various analogies offered by physiology and pathology, which show that the function last and with greatest difficulty acquired is the first to be lost. In this instance Stratton's experiments again corroborate the theory. He found that the lateral relationships were the hardest to acquire. Common experience teaches us the same, even the mature adult frequently having difficulty in distinguishing the right from the left.

Our thesis then is this: The outer world is impressed upon the retina in an inverted image. It is only by experience laboriously acquired that we learn to interpret this image and to produce upright writing. The child and the feeble-minded, lacking this experience or unable to acquire it, reproduces the visual image in incorrect spatial relation, hence in mirror or completely inverted writing. The adult suddenly deprived of this experience is reduced to primitive conditions, hence produces the same results which we see in the child.

DISCUSSION.

DR. G. C. SAVAGE, Nashville—In the first place allow me to say that without being able to offer any explanation for it at all, I believe it to be a truth that the normal eye has a certain plane that should be parallel with the median plane of the head and that that plane bisects the retina. I believe there are two different things connected without vision, that some are gifts and some matter of acquisition. Direction I believe to be a gift and I do not believe we can acquire an idea of direction. I believe that color is another gift, and do not believe we can acquire a sense of color. That direction may be interfered with occasionally I grant and we can not explain why one person has a perfect sense of color and another person an imperfect sense of color, and the same applies to the sense of direction. The things that come by acquisition are the appreciation of form, size, distance, etc. Now, in explanation of the gift of direction, someone, I think it was Cunningham, discovered the law of direction 150 years ago, and if I am right about it then the sense of direction is easily explained, and I believe that the law of direction is that every line of direction must begin at a point on the retina, impinge at the point of light forming the image and pass from that upwards, downwards, outwards or inwards and thence on into space.

I am not going to explain why it is that a child writes a letter now and then that is inverted, but I do believe that sometimes we may be deceived by the statement of individuals. I well remember the report that many of you saw a few years ago from an Arctic explorer who wanted to see whether the Eskimos saw things inverted or as we see them. He gave one of them a pencil and paper while they were looking at a white bear, and asked him to draw an outline image of the bear. The man did so and the explorer reported that the image drawn was an inverted one. Now, I insist that there was something wrong either with the Eskimo or the explorer. In spite of the criticisms of the views I published some years ago, I hold yet to that theory.

DR. A. B. HALE, Chicago—I did not want to lead the Section into a discussion of the psychology of the retinal image. All I assume is that the retinal image is an inverted one that is transferred to the brain which reproduces it. If Dr. Savage will think a moment he will see that these images are not what the man saw, but copies of what he remembers he saw. The explorer Dr. Savage refers to was probably Dr. Cook, who found that the Eskimos used picture books and such things upside down, even the children; in other words, they were a primitive people and had not been trained to see things as we are. Dr. Cook was not at all satisfied with the picture of the bear. If Dr. Savage will study Stratton's paper he will find an interesting work on the question of the acquisition of the sense of direction.

DR. ARTHUR SWEENEY, St. Paul—It is apparent to any one who looks seriously into the subject of mirror-writing that it is not confined to those who are mentally weak, but is found in considerable proportion among those of normally developed intellects. I have among my friends found several who wrote mirror-writing while at school, although right-handed. Others, who invert the paper when writing or who turn it sideways, drop into mirror-writing when compelled to write with the paper in the usual position. The subject has heretofore been considered mainly from the standpoint of mechanical ease, rather than as a perceptive defect. The theories of Erlenmeyer and others who have accounted for the phenomenon on the basis of facility of muscular movement have hitherto been accepted as settling the question. I am glad to see that Dr. Kuh has not been misled by this attractive but faulty hypothesis. The phenomenon is essentially dependent on failure of the mind properly to perceive the position of objects in space. The retinal image is an inverted one, and is transposed by the association of impression coming from the perception of light, ocular movement and the knowledge acquired by the sense of touch. Any influence that prevents the proper association of these three factors interferes with the transposition of the retinal image. The eye is in constant motion. If it was still, only a limited number of rays would fall upon the yellow spot. When we look at an object however small, it is necessary, in order to perceive its length, breadth and other relations, that the eye should be moved so as to bring the rays in succession upon the yellow spot. This movement of the eye is slight except when the objects are large or near. This ocular movement is, in my opinion, the most easily disturbed factor in the transposition of the image. It is a purely reflex act, instinctive in character. In the case of Hilda Olson, reported by me a year ago, who had complete inverted vision, there was an astigmatic hypermetropia of 2.5 degrees. This necessitated a flattening of the eye at each accommodative effort, and as two reflexes can not co-exist, the stronger one suppressed the weaker, so that the reflex of ocular movement, so necessary a factor in the transposition of the retinal image, was not operative. The correction of the hypermetropia by glasses gave her normal perception of the position of objects in space. I am glad to see that Dr. Kuh has recognized the purely perceptive nature of the defect, and that it is really a failure of co-ordination of impressions that is at the root of this most curious and interesting phenomenon.

DR. RICHARD DEWEY, Wauwatosa, Wis.—I am induced to speak of certain phenomena that I am reminded of as having occurred in my own experience which will possibly add force to what has been said regarding the importance of co-ordinate action of the brain in the reception of an impression. Any one who has given this question much thought must have reached the conclusion that there is something in the condition of the brain itself in receiving impressions, whether they relate to the tactile, visual or any other sense. My personal experience has convinced me that in order to receive an impression, there must be a certain preparedness on the part of the brain for its reception. For example, I have sat at the table with a glass of water and another of milk before me, and unconsciously taken a taste of one liquid instead of the other. This gave a strange perception of something that was neither milk nor water, and it was only explained when I found that I had taken something into my mouth under the impression that it was a different thing. I recall another example of this mental confusion. In passing from a room into a hall where I expected to find a window I found instead a blank wall, and this gave rise to a momentary period of confusion in my mind, because I saw something that was not what I had expected to see, and it took an instant for the eye and brain to adjust itself to the fact.

DR. HERMAN GASSER, Platteville, Wis.—The correction by glasses in the case referred to by Dr. Sweeney makes it evident that there is no such thing as inverted or perpendicular images. "Thinking is pushing and pulling." Every ray of light that falls upon the retina causes a chemical reaction, with a transformation of its energy into nervous energy, and then is transmitted by the optic nerve to the visual center in the brain by modes of motion. When these impressions are received unphysiologically or incorrectly, the result of habit or error of refraction, they are carried thus to the cortical brain and adjusted to all the other senses of touch, hearing, etc., into the conscious existence which we call mind. That is why there is no such thing as an inverted mental image. It is simply the way we receive certain impressions. The normal or abnormal images are the result of the adjustment of the forces of the outer world as we perceive them with their definite relations by our sensory apparatus and build them into ideal states of mental existence. The mental image and the "image" or reality outside that gave it existence are entirely distinct. This is why if our sensifacient apparatus is not normal we may have what we call abnormal and "inverted" images, but that appear as normal to the individual as was observed in the case where the glasses corrected the error of refraction and it at once was observed in what we term the normal relation.

DR. SYDNEY KUH, in reply—I think Dr. Sweeney and I agree that this is a disturbance of co-ordination. That is the important factor, but such a disturbance of co-ordination may be due to a variety of causes. If any one of the factors that

take part in the formation of a mental image is disturbed, a faulty mental image must of course result. One of the possible factors of this kind is a defect of the ocular movements. The fact remains that not in a single one of the cases of mirror-writing occurring in hemiplegics coming under my observation was there the slightest disturbance of the ocular movements. I do not think that a disturbance of the ocular movements is of any greater importance than a disturbance of any other organ that assists us in forming a mental image.

SCHOOL MEDICAL INSPECTION IN CHICAGO.

WILLIAM D. BYRNE, M.D.
MEDICAL INSPECTOR SUB-DISTRICT 37.
CHICAGO.

That school medical inspection is at last receiving the merited attention of enlightened school boards and health officers in our larger cities argues well for its future, and adds additional luster to the fame of these medical pioneers who first introduced and championed its cause in humanity's interests. This great aid to prophylaxis was foreshadowed in those admirable German laws which went into effect July 14, 1884, by the adoption of the Prussian Circular to the Royal Governors of Provinces, which concerns the closing of schools in the event of the occurrence of infectious diseases. The diseases and the laws pertaining to them are classified as follows:

1.—*a*, Cholera, dysentery, measles, rubella, scarlet fever, diphtheria, smallpox, typus, relapsing fever, cerebrospinal meningitis; *b*, typhoid fever, contagious inflammation of the eyes, itch and pertussis (while spasmodic).

2. Children suffering from these diseases are to be excluded from school.

3. Healthy children living in same house in which cases named in 1 exist—Exception: it must then be certified by a physician that the school child is protected from danger of infection by proper separation.

4. Children excluded from school for said causes may be readmitted only after the danger of infection has been removed according to a physician's certificate or the usual duration of the disease has expired. This, in the case of scarlet fever and smallpox, is 6 weeks, and for measles and rubella four weeks, from its inception. Regard must be paid to the thorough cleansing of the child's person and clothing before readmission to school.

5. For the observance of orders 2 and 4 the principal or headmaster is made responsible. An immediate report of the exclusion of a child from school on account of an infectious disease must always be made to the local police authorities.

6. Refers to isolation of children attending boarding school when an epidemic occurs. It requires a physician's certificate to release them from quarantine, which he will give only when convinced that the danger of spreading disease is past and all precautions have been observed.

7. When any person living in the school house falls sick of one of the infectious diseases named in 1, or if a case should occur in the household of a school teacher, said case must be reported to the principal and to the police authorities, when proper steps must be taken to isolate the infectious case.

8. When several cases of infectious diseases, as in 1, appear in the locality where the school is situated, the principal and teachers must direct their especial attention to the purification of the school property, to the thorough airing of the class rooms. In particular must the school rooms and sanitaries be carefully cleansed each day. School rooms are to be aired continuously when not in use and the sanitaries must be regularly disinfected according to the regulations of the district police authorities. This rule applies to boarding schools and in them is extended to include dwelling rooms, work rooms and bedrooms of the pupils.

9. School rooms and entire schools where infectious diseases appear in epidemic form must be closed when the district physician advises.

10. Reopening is permissible only after thorough previous cleansing and disinfecting of the premises and on the advice of the district physician.

11. These laws apply as well to parochial and private schools, orphanages, asylums, day missions, and kindergartens.

The foregoing laws, admirable in their way, have furnished the basis upon which most of our state and municipal bodies have founded their regulations appertaining to the same subject. They, however, fall short of the ideal, inasmuch as they do not provide for systematic daily medical inspection, and, to remedy this defect, the practical American rises to the occasion and medical inspection of schools is born.

The first attempt at this work was made in the parochial schools of Philadelphia in 1889, but was discontinued on account of parental objection. To Dr. S. H. Durgin, of Boston, is due the credit of the first victory in this field. Beginning to agitate the question in 1890, he encountered much opposition, but, aided by Dr. C. M. Green, a member of the School Board, he succeeded in overcoming it. Following a serious epidemic of diphtheria he induced the board to sanction medical inspection as a regular department of school life. His important victory dates from Nov. 1, 1894. From that date to Oct. 31, 1896, there were individual examinations of 23,207 pupils, disclosing 6,571 cases of major and minor ills. Of them 5818 were ill enough to be sent home, many of them suffering from markedly contagious or infectious diseases.

The importance of the work is also emphasized when the total school population of Boston at that time is considered. The figures show the presence of 71,495 pupils in the public schools and 11,808 in parochial schools. Roughly then, 10 per cent. of these pupils required medical inspection, and it need scarcely be said that many cases of infectious diseases were thus promptly isolated, to the material benefit of the pupils in normal health.

Attracted by the excellent results shown in Boston, Dr. Charles F. Roberts, Sanitary Superintendent of the New York Bureau of Health, in October, 1896, sent a recommendation to that body urging systematic daily examination of the school children by medical inspection of the Health Department, and, although preliminary investigation proved the immediate necessity for such work beyond the shadow of a doubt, the work was not regularly instituted until March, 1898. Thereafter in three months 63,812 children were examined by the inspectors, and of these 4,183 were excluded on account of contagious diseases.

About the same time the Chicago Health Department, through its regular medical inspectors, working on notification of infectious diseases, received by the department from physicians attending the patients, during four months, visited 233 public schools, locating 1417 cases of diphtheria and 306 of scarlet fever. Despite the urgent demand for such work, it was not until Dr. W. S. Christopher was appointed as a member of the School Board that that body acted upon the recommendations of the Health Department. A corps of fifty medical inspectors was appointed by competitive examination under Civil Service rules, and Jan. 8, 1900, the work was begun. From that date to April 12, 1900, the inspectors examined 76,805 pupils, the school population at that time numbering 200,000. Of these 4539 were found suffering from contagious diseases and excluded from school. Resuming September 17, the work was continued until November 8; it was resumed again

from January 8 to March 1, 1901, and during this time examinations to the number of 56,562 were conducted, the exclusions numbering 3398. Following are the figures of the Chicago Health Department covering diphtheria and scarlet fever for the year preceding medical inspection of schools and the first year under such inspection:

	1899				1900			
	DIPHTHERIA.		SCARLET FEVER.		DIPHTHERIA.		SCARLET FEVER.	
	Cases.	Dths.	Cases.	Dths.	Cases.	Dths.	Cases.	Dths.
Jan.	381	82	306	26	572	111	805	48
Feb.	307	62	377	41	362	88	505	47
March.. .	284	55	522	68	315	82	435	21
April ...	240	56	507	71	229	67	303	19
May	266	55	512	68	230	58	338	26
June ...	248	63	370	43	211	58	207	18
July	174	47	269	20	158	41	142	10
Aug. ...	235	60	256	28	103	33	92	2
Sept. ...	241	75	327	31	187	42	107	4
Oct.	489	93	747	35	306	79	160	13
Nov.	608	92	888	53	317	72	170	6
Dec.	458	103	719	49	313	66	211	12
Total.	3931	843	5800	533	3303	797	3475	226

It is thus seen that a decrease in the number of diphtheria cases was 628 for the year, with 46 fewer deaths. In scarlet fever the decrease in cases was 2325, with 307 fewer deaths.

These figures make even a better showing when it is considered that physicians as a rule were more careful in 1900 to report cases of this nature to the Health Department than in previous years, and the rapid growth of Chicago must also be taken into consideration. These facts add much to the excellent results shown in the foregoing table.

Viewed from the point of the economist, preventive medicine adds vastly to the wealth of the nation. Placing the low figure of $1000 on the economic value of a human life, properly conducted medical inspection adds many hundred lives to the credit side of the nation's ledger every year, and thus proves one of the most profitable fields in which preventive medicine finds its work. At the same time the fact that it may be the saving the life of a Hippocrates, a Michael Angelo, a Wagner, a Robert Browning, a Morse, Edison, Lincoln or Gladstone should never be forgotten in estimating its potential value.

In Chicago during the early months of medical inspection of schools, some objection developed on the part of parents who did not understand its aim, but this gradually died out and now the vast majority of them are very much in favor of it. One instance of the good work done through medical inspection exerted much influence with thinking parents. This occurred during the winter of 1900-1901 at the D. S. Wentworth school. Four children of the G———— family—two boys and two girls—attended this school. The oldest child, a boy of 13, developed a sore throat. His parents, aided by the neighbors, made a diagnosis of "mumps." He was kept at home Tuesday and the remainder of the week, but not until Friday did they call a physician to see him. The boy was then moribund from malignant diphtheria, and died within 48 hours. His sister, aged 10, contracted the disease, but she recovered. The Board of Health was notified of the circumstances and immediately closed the three school rooms where the other children of the family had attended during the week. These rooms were then thoroughly disinfected and the throat of every child in each room examined. All suspicious throats had cultures made from them and the children were sent home pending announcement of the results. This thorough work was kept up for two weeks but no new cases were discovered, and, at the expiration of that time, the quarantine ceased. The foregoing is but one of many instances of a like nature where prompt and efficient medical inspection undoubtedly prevented the occurrence of an epidemic.

One of the most disagreeable duties of inspectors is to examine and exclude children afflicted with pediculi. One irate parent whose four children had been excluded from school kept after the writer for a month. During that time he complained to several members of the Board of Education, including its president. He also took the matter to the local alderman, alleging every reason but the right one as the cause of exclusion. These men took the matter up, but on learning the truth referred him back to his school principal and medical inspector. Finally he gave in and saw that his children had proper attention. They became models of cleanliness and were never again sent in for examination on that score.

In Chicago the branch of medical inspection is under the supervision of Mr. W. L. Bodine, Superintendent of Compulsory Education, to whom the medical inspectors are responsible for the proper discharge of their duties. A daily report of cases examined and excluded is mailed by each inspector at the close of his day's visits to Dr. Arthur R. Reynolds, Commissioner of Health, and a copy is sent him also for transmission to Superintendent Bodine. In case of emergency, such as an outbreak of smallpox, diphtheria or scarlet fever, inspectors telephone immediately to both departments and thus no time is lost in establishing efficient quarantine.

Following is a copy of the instructions to medical inspectors, under which Chicago medical inspectors work:

The pupils to be inspected will be referred to the inspector by the principal for two reasons: 1. Those who have been absent four or more consecutive days.

2. Those in the school whom the principal may suspect to be suffering from contagious diseases.

These two classes must be kept separate in the reports.

The inspection is to be made with reference to transmissible diseases only, and examination is to be made for the following diseases; scarlet fever, diphtheria, measles, roetheln, smallpox, chicken-pox, tonsillitis, lice, ringworm, or other transmissible diseases of the skin and scalp, and transmissible diseases of the eye.

Scarlet fever cases must be excluded until desquamation has ceased.

Diphtheria cases must be excluded until throat culture shows the absence of the Klebs-Loeffler bacillus.

Severe tonsillitis cases must be excluded on the clinical evidence alone, and throat culture made for further diagnosis.

Cases presenting suspicious throats, but not definite evidence of disease clinically, must have throat cultures made, allowed to return to their classes until the culture has been examined, and only excluded in case the bacteriologic examination shows exclusion to be necessary.

In making throat examinations the wooden tongue depressors supplied must be used, to the exclusion of all other tongue depressors. *Each tongue depressor must be used only once.* Aseptic methods must be employed in all examinations.

If a child is excluded, brief but sufficient reason therefor must be written on the exclusion card.

Inspectors are forbidden to make any suggestions as to the treatment or management of pupils who are sick. *This is imperative.*

Unlike Boston and New York, Chicago, though fully alive to the value of medical inspection, has not as yet made sufficient provision for the permanent employment

of its entire corps of medical inspectors. The emolument is $50 per month and, to cover the ground properly, a man must devote his entire working morning to the service, i. e., from 9 a. m. to 12 m. When the appropriation runs low four-fifths of the inspectors are dismissed and an emergency corps representing the three major divisions of the city is selected from the eligible list. These inspectors do not make daily visits but respond to special calls from a school principal when in his opinion local conditions demand attention. This method does not, of course, compare with the regular daily visits of qualified physicians but seems to be the best that can be done by the School Board when financial stress is acute.

That feature of the Boston system relating to the discovery of infectious disease in the schoolroom, in which event the medical inspector orders the child sent home, reports the case to the Board of Health and follows the case home to see that it is properly isolated there, shows a defect in the Chicago system. When recovery is reported, in the former city, by the family physician, the inspector determines whether all danger of spreading the infection has ceased.

Another improvement might be adopted from the New York rules in this matter, viz., that provision requiring the principal or head teacher in charge to make weekly reports of the names and addresses of all absentees and, if absent on account of illness, naming the disease if possible. In Chicago such list might be handed to the local truant officer who has the right to enter the houses of all absentees, and he might then report his findings to the Commissioner of Health for further action.

Several years ago a New York paper suggested a valuable aid in preventing the spread of infection among school children, i. e., the separate wardrobe. This may be constructed of board, making each partition eight inches deep, or sufficiently large to separate the clothing of each child from that of his neighbor. A weekly cleansing or disinfecting of these wardrobes might be accomplished with but slight expense and most excellent results. This would prevent the spread of many parasitic skin diseases and minimize the spread of more formidable contagions.

Again, much better results might be had by enlisting the active co-operation of all the teachers in the work of detecting disease. This might be accomplished by printing and distributing a placard such as Dr. Meredith Young, Medical Inspector of Crewe, England, has originated for use in the local schools. It bears the caption: "Particulars of Certain Contagious and Infectious Diseases for the Guidance of School Teachers." A copy of this placard is hung in every schoolroom in the district. The diseases enumerated are divided into two classes, A and B. Those in class A include scarlatina, diphtheria, measles, rubella, mumps, pertussis, varicella, variola, and influenza. In class B are listed erysipelas, ringworm, diseases of scalp, scabies, and purulent conjunctivitis. When diseases enumerated in the former class occur, all children living in the same house are excluded from school; in case of those in the second, class B, the exclusion of the actual sufferer alone is insisted upon.

In conclusion, one of the great aims of modern medicine is prevention: for it is written "An ounce of prevention is worth a pound of cure." And it is the endeavor of the Medical Inspector of Schools to live up to this adage. That he is doing so is acknowledged by all those who have given the matter thought, and when the history of Preventive Medicine, as practiced in the twentieth century is written, posterity will undoubtedly award a high place to the daily medical inspection of schools.

TWO DIFFERENT WAYS IN WHICH YELLOW FEVER MAY BE TRANSMITTED BY THE CULEX MOSQUITO—STEGOMYIA TAENIATA.

CHARLES J. FINLAY, M.D.
HAVANA, CUBA.

Had it been known in 1881 when I reported my first inoculations with contaminated mosquitoes, that eight or ten drops of blood from a yellow fever patient injected under the skin of a non-immune would almost surely produce an attack of the disease, as Dr. Reed and his colleagues have now clearly proved, my discovery of the transmission through the bite of the culex mosquito would have been considered quite plausible.

My experiments would have been taken up and repeated under more satisfactory conditions, the number of mosquitoes required in order to produce a characteristic reaction would have been ascertained, and, probably, twenty years of ignorance on that important subject would have been spared to the medical profession. Without stopping to discuss the nature of the specific germ, the bare knowledge of the fact that the prick of a needle, previously moistened with the lymph of a smallpox or varioloid vesicle, suffices to produce an attack of variola, would have induced my colleagues to interpret my experimental results in accordance with my own ideas. After the infecting bite upon a yellow fever patient some of the germs contained in the blood are likely to remain attached to the parts constituting the sucking apparatus of the insect, so that when the same mosquito is allowed, two or three days later, to bite a non-immune the said germs may be deposited along the track of the wound or washed down into the wounded capillary vessel by the saliva or venom which is usually discharged during the biting and sucking operation. I had at first experienced some difficulty in fitting this interpretation to an essential condition stipulated in my "mosquito theory," namely, that the insect which should transmit the disease must belong to a particular species, different from those normally found in countries and seasons where and when the disease does not appear to be transmissible. I have thought, however, that the salivary secretion of the culex mosquito may possess special conditions enabling the yellow fever germs retained upon the sting to preserve their vitality, perhaps to sporulate, during the interval of days which must elapse between two successive bites. There must be a limit, however, to this anomalous vitality of the germ, which probably may not be prolonged beyond four or five days. This would account for the circumstance that I had never obtained any pathogenic reaction, nor any evidence of subsequent immunity, with my inoculations during the winter season, when the mosquito requires a longer time to digest its feed of blood and often will not bite a second time before a lapse of four, five or six days. My technique was a very simple one. The mosquitoes were caught in my own dwelling, at a time when no cases of yellow fever were supposed to exist in the neighborhood, and after having ascertained by their bright markings and general appearance that they were young insects, probably not more than a few days old, each was confined in a small phial or test-tube

without food or water. The insects were then taken to one of our hospitals and the yellow fever cases carefully examined until one with severe symptoms could be found, not farther advanced than the sixth day (usually on the third, fourth, fifth or sixth) of the attack. The mosquito was then made to fill itself with the blood of the patient, and left to digest its feed of blood, imprisoned within the same phial. In the ordinary course of events, in summer, the insect would be ready for another bite after the lapse of 48 to 60 hours; on some occasions, it would then be made to bite a second yellow fever patient, in which case another interval of days would have to be allowed before applying the contaminated mosquito to a non-immune.

I have carried out the above procedure, in collaboration with Dr. Claudio Delgado, upon 102 non-immunes in the course of 17 years (1881 to 1898). In 17 of the inoculated persons some febrile reaction occurred after a number of days varying between five and seventeen, in 14 of them, and as late as the 22d, 23d and 25th in the 3 others. The reaction consisted in a mild albuminuric attack of yellow fever in 2; in a distinct non-albuminuric attack of the disease in 6; in an abortive attack, with or without traces of albuminuria, in 3; and only an ephemeral fever, of doubtful diagnosis, in 6. Of these 17, two of the 6 who had experienced only ephemeral reactions showed no immunity at all, having been attacked with severe yellow fever in the course of the same year or the next; of the 3 with abortive reactions, one had another attack of the same character two years later; of the 6 who had developed a non-albuminuric yellow fever after their inoculation, one went through another attack of the same type a few months later, on severe exposure, a fatal case having occurred in the room next to the one which he occupied; neither of the two who had presented a mild albuminuric attack after the inoculation ever experienced any subsequent attack of the disease.

Nearly all our inoculations were performed upon persons who had come to stay several years in Cuba; only 10 of the 102 left the island before having completed their fourth year, the rest lived from four to twelve years in Havana (a few spent part of that time in Cienfuegos or Matanzas). Only 4 of the total number (less than 4 per cent.) died of yellow fever; 2 of them five and eight months after their inoculations, the 2 others after five and six years; none of them had reacted after their inoculations. Among all the 102, during their entire residence on the island, independently of the attacks attributed to the inoculations, 4 had fatal hemogastric yellow fever, as previously stated; 19 had albuminuric yellow fever, mostly of a mild type, but 4 of them severe with some hemogastric tokens, all recovered; 17 had non-albuminuric yellow fever, and 9 had abortive yellow fever, including 2 who only developed a suspicious ephemeral fever. The remaining 53 never experienced any form of the natural yellow fever during the years which they spent in Cuba after their inoculations.

I had thought of two ways by which more decided experimental results would be obtained; one way was by applying several contaminated insects at a time; the other to consist in feeding the mosquito exclusively on sugar, during two or three weeks after they had bitten a yellow fever patient, and only applying them after the lapse of that time to a non-immune. From a careful study of Melier's famous report of the epidemics of St. Nazaire, in 1861, I had come to the conclusion that it was in consequence of conditions such as these that the contaminated mosquitoes which had sought shelter in the hold of the *Anne-Marie* during its trip to St. Nazaire, must have acquired the intense virulence which enabled them to inoculate with fatal yellow fever every person who entered the hold of the vessel after its arrival at that port. It was on these grounds that I wrote, in a paper dated December 31, 1891, the following words: "It is my belief that, while one or two stings from recently contaminated mosquitoes can only occasion in susceptible persons a mild attack or simply confer immunity without any pathogenic manifestations, a severe attack would result from a greater number of such stings and the same might occur in consequence of one single bite from a mosquito which had been fed exclusively on sweet juices during several days or weeks after its contamination, before being allowed to sting another person."

At that time I still attributed the increased virulence to the multiplication of the germs which had been retained within the sucking apparatus of the mosquito; but in 1898 I read before the Academy of Sciences of Havana a paper in which I suggested, as the reason why only the Culex mosquito, alone among its Cuban congeners, has the faculty of transmitting yellow fever, that it has a pathogenic susceptibility for the yellow fever infection which the other species have not; the infectious germs would multiply within the body of the insect and finally reach its salivary and venom glands, to be carried with the secretion of those glands into the track of the wound or into the capillary vessel entered by the sting when the mosquito attacked another victim.

The Military Yellow Fever Commission, presided over by Dr. Reed, was evidently unacquainted with the last mentioned developments of my mosquito theory when they undertook to investigate it in August and November, 1900, since it was exclusively from precedents recorded about the malaria germ that they were induced to adopt the second procedure which I have outlined above. They have proved conclusively the surest way of obtaining a distinct experimental attack of yellow fever is by proceeding in the following manner: The mosquito *must* be applied to the yellow fever patient within the first three days of the attack; the insect is thereafter to be comfortably quartered in a good-sized jar, provided with sugar and a small cup containing water, in which it may moisten its proboscis and obtain facilities for laying its eggs. With such an arrangement the insect may be kept alive during seventy days or more, though a good many die long before that age. With mosquitoes treated in this manner Dr. Reed and his colleagues have tried to develop an experimental case by applying them to non-immunes five, six, eight and ten days after those insects had bitten the yellow fever patients, but they have invariably failed to obtain any positive results under these conditions, while they have succeeded in a large majority of their attempts when the application of those same insects had been delayed until twelve, sixteen or more days after their contamination. From these results Dr. Reed and his colleagues conclude that the yellow fever germ must be a parasite similar to that of malaria, and that, after parting from its human host, it must go through a series of transformations during the mosquito phase of its existence, requiring at least twelve days for their completion, before it can be in a condition to reproduce the disease. As a corollary to this proposition they believe that my previous experimental attempts must have been failures or errors of interpretation, since they are supposed to have been obtained with mosquitoes contaminated only a few days before the inoculation; they also claim that their point has been experimentally dem-

onstrated by the fact that their mosquitoes, when applied from five to ten days after their contamination, have invariably given negative results. The investigators thought, no doubt, that by providing their contaminated insects with food and water, besides giving them the benefit of several additional days since their contamination, they were actually improving upon my original technique; their argument being that since their inoculations had failed, even with those improvements, it was incredible that I should have succeeded in any of my attempts with my simpler method.

It has, apparently, not occurred to those able investigators while criticising my former experiences, to consider a fact which they have themselves demonstrated, namely, that there are two different ways by which the specific germs of yellow fever may be conveyed from the sick to the healthy. One way consists, as I infer from their experiments, in allowing the yellow fever mosquito to become infected in such a manner that, after the lapse of a certain number of days, the salivary and venom glands of the insect appear to become the seat of a local, chronic, lifelong infection, which is attended with a constant reproduction of yellow fever germs, so that the contaminated mosquito will thereafter inoculate some of those germs with every bite. The other way consists in injecting the germs contained in the blood of a yellow fever patient directly under the skin of a non-immune. I am not aware that any attempts have been made to determine the length of time during which the specific germs in the blood may retain their vitality within the glass cylinder of the hypodermic syringe or in any other receptacle.[1] but it stands to reason that they will survive more readily within the blood-sucking apparatus of the yellow fever mosquito, normally moistened with the insect's saliva, which admittedly constitutes the ideal culture medium for the yellow fever germ. Yet there must be a time limit beyond which the germs retained within the sucking apparatus must lose their vitality or perhaps undergo transformations which may temporarily deprive them of the power of reproducing the disease. During that limited time, under favorable circumstances, they may even sporulate and multiply as they might have done within the human host, but, on the other hand, it must be remembered that their position in the internal mouthpieces of the insect must be a precarious one, being at every moment liable to be washed out by a discharge of saliva or to be drawn into the stomach of the mosquito whenever food or water is sucked.

From these considerations it must be inferred that the bite of a yellow fever mosquito which has sucked the blood of a severe case is likely to prove infectious for non-immunes at two separate periods, namely, during the first few days after the insect has bitten the patient, provided that, in the meantime, the mosquito has not had access to any food or water, nor been allowed to bite another subject. After this short period the bite of the insect may be harmless until ten or fifteen days later, when the germs within the body of the insect will have had time to multiply and to invade its salivary apparatus.

The direct infection through the bite of recently contaminated mosquitoes, so far as I can judge from personal experience, produces much milder pathogenic effects, the fever is much less prone to develop albuminuria, and the period of incubation is often prolonged. I believe that after this mode of infection has been duly verified, and with certain improvements, including the employment of home-bred insects and the proper adjustment of the number of these necessary to secure visible pathogenic effects, it will be found to constitute the only method which may be safely used, upon a large scale, for the purpose of conferring immunity.

I certainly do not claim for my experimental results, obtained under difficulties and with considerable personal inconvenience, the significance and conclusiveness of the experiments so admirably carried out by the Military Commission at Camp Lazear; but, after the preceding explanations, every reader must admit that my method of inoculation has, so far, not been investigated by that commission, and that they are, therefore, in no position to pass judgment upon its merits before having done so.

160 Campanario Street.

1. Since writing the above, I have been informed of a recent experiment by Dr. Carroll, at Camp Columbia, showing that the blood of a mild experimental case of yellow fever, kept over night and part of the next day (some 14 hours) and injected to a non-immune has produced a mild but characteristic attack of the disease.

TREATMENT OF RINGWORM OF THE SCALP IN INSTITUTIONS.*

HENRY W. STELWAGON, M.D.
PHILADELPHIA.

The hospital or institution which escapes the misfortune of having to care for cases of ringworm of the scalp has much for which to be grateful. Many such cases occurring in private practice, among properly cared for children of good physique and robust health are, if the disease is at all recent, usually rapidly responsive to well-advised measures. Not so with hospital and institution cases. Even in private practice observation shows that in cases of any duration the disease is frequently rebellious and persistent, and that in many instances the practitioner pronounces the cases cured when the hair has begun to fill in in the affected area or areas; whereas, in reality the disease may still persist in a less conspicuous but chronic state, and the case remains an active center of contagion for other children. In almost all institutions in which children with this disease are admitted or in whom it may develop subsequently to admission, the subjects are almost invariably of poor stock, of impoverished nutrition, and have had, as a rule, the disease many months before coming under treatment. The consequence is that one has to deal with a persistent, rebellious and troublesome type scarcely known to the average practitioner, but an all too common experience with the specialist in skin diseases. With persevering treatment even the most of these cases may be made to yield in some months, or say within a period varying from several months to a year. Exceptionally a longer time is required for cases of great extent and of long duration. Without the methodical and persistent carrying-out of treatment, however, such cases last almost indefinitely—or till Nature begins to look after the cure as the child verges into puberty.

Ringworm of the scalp is in the larger number of cases due to the small-spored fungus, and, as a rule, it may be accepted as a fact that this fungus is the agent in most of the refractory cases. In a fair proportion of scalp cases, however, the disease is due to the large spore variety, and while such yield much more rapidly in most instances, still there are cases due to this variety of fungus which also prove persistently obstinate. Whichever fungus is the causative factor, the treatment

* Prepared for the St. Paul Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery.

remains the same. As yet we know that the recognition of the fungus variety has a bearing simply upon the prognosis as regards the probable time for a cure.

Strong remedies must, as a rule, always be used in the treatment of scalp ringworm in institutions. There are cases, it is true, in which the inflammatory element is, at first at least, quite marked, and milder applications are usually demanded. In such cases, indeed, this inflammatory element may be said to be a natural attempt toward casting off the disease. In almost all cases, sooner or later, however, the strong remedies are to be prescribed. What are they? In a great measure, one might say that the selection depends upon the habit or the prejudice of the prescriber. Still there is considerable unanimity among those having to do with these chronic cases as to the several remedies possessing greatest value. My own experience emphasizes the usefulness of sulphur, naphthol, iodin, chrysarobin and croton oil. Sulphur and naphthol are most valuable and appropriate for those cases involving a greater part of the scalp. Chrysarobin and iodin for circumscribed areas, and croton oil for those patches which have persistently failed to yield to other remedies.

There are certain adjuvant measures which should be mentioned first, before taking up the manner of application of the above several remedies. First, the hair of the entire scalp should be kept clipped very short, about one-fourth to a half inch in length. The disease is then more easily watched, and any new spots detected in their incipiency and promptly treated. In extensive and extremely obstinate cases it is even desirable to have the scalp shaved every five or six days. The spread of the disease to other parts of the scalp and to other children should be prevented by certain routine measures. With this object in view, the scalp is to be washed daily or every second day with warm water and medicated sapo viridis:

℞. Sulphuris præcipitat. 3i
Naphthol .....gr. xxx
Saponis viridis .....℥i M.

The lather should be permitted to remain on for five to ten minutes, as it has in itself, as experimentally shown by Thin, an inhibitory or destructive influence upon the fungus which may be scattered about the parts. If there is fear of taking cold, the scalp may be enveloped with some covering. The lather is thoroughly rinsed off, the parts rubbed dry, and then a general remedial application made, chiefly for the purpose of prevention, to the entire scalp. The following is useful for this purpose:

℞. Sulphuris præcipitat. 3i
Naphthol .....gr. xxx
Petrolati .....℥i M.

Or, instead of the salve, a lotion may be used for this general application, consisting of:

℞. Acid. carbol. 3ii
Resorcin 3i
Solut. acidi boric. (saturat.) .....Oi M.

It is possible that the salve is more effectual in preventing the dissemination of the spores, although it is not so agreeable.

A word as to depilation of the affected areas. This is a measure of some importance, if carefully and repeatedly done, but if the disease is at all extensive or the patient very young, it becomes almost impracticable. As an efficient substitute for this, originally suggested, I believe, by Dr. A. W .Brayton, and in my judgment of superior value, and also possessing therapeutic properties of its own, I can cordially recommend a good depilatory powder. The following, if properly and freshly prepared of good materials, will answer the purpose:

℞. Barii sulphidi 3iii
Zinci oxidi
Amyli pulv. āā .....3iiss M.

At the time of application enough water is added to this mixed powder to make a paste, which is spread in a layer of the thickness of the back of a table knife on the areas, slightly overlapping the edges; this to remain on for three to fifteen minutes, according to the character of the hair and the sensitiveness of the skin; or until heat of the skin or a burning sensation is felt. It is then thoroughly washed off, and if it has acted as it should, the hair of the patch, including the stumps, will have been destroyed deep into the follicles, and possibly to the full depth of the latter. Should there be accidentally much irritation from this, a soothing ointment may be applied for a few hours or a day; as a rule this is never necessary. The depilatory should be applied every five to ten days, depending upon the rapidity of the regrowth.

As to the remedial applications to the individual areas, the same ointment as above, with double the quantity of sulphur and naphthol, will prove valuable in recent cases and especially in very young subjects. The following is the formula:

℞. Sulphuris præcipit. 3ii
Naphthol .....gr. xxx-lx
Petrolati .....℥i M.

Occasionally the larger amount of naphthol, in those of extremely sensitive skin, gives rise to a feeling of considerable burning, and in such cases this ingredient can be reduced in quantity. As a rule, however, the feeling of burning is over in a few minutes, and no active irritation follows. Ordinarily, the best application for the areas in young patients and in recent areas is iodin tincture, containing a small quantity of mercuric iodid:

℞. Hydrarg. iodid, rubri .....gr. i-iii
Tinct. iodini .....℥i M.

I am convinced that the value of iodin tincture applications in this disease is much underrated. The preparation is painted on twice daily, two or three coatings at each time, till the parts become somewhat tender or till the film thus formed cracks or begins to loosen. The parts are then anointed with the milder of the above salves, and as soon as the film is detachable it is picked or pulled off. If there is active underlying irritation, which is rarely the case, a mild ointment may be applied for a day or so. According to circumstances as indicated above, the depilatory powder is again used, and the paintings resumed. This is continued till the new growing hairs show no evidence of fungus, and then the treatment is discontinued, and the patient kept carefully under observation for several weeks. Should signs of the disease again present—if necessary their significance should be confirmed by the microscope—the paintings are again resumed. Or, if the iodin paintings seemed to be slow in bringing about a complete cure, another plan is to be instituted.

Chrysarobin is by far the most valuable application in most of the hospital cases. It must be of the first quality. It is made by various manufacturing chemists, and varies considerably in quality; naturally an efficient preparation is essential for success. It may be used in all cases, but must be employed with greater care in patients under the age of three years. In most of the younger patients in fact the sulphur naphthol salve or the iodin paintings will suffice to bring about a cure.

Chrysarobin is most satisfactorily applied as a solution in chloroform:

℞. Chrysarobini .....q. s.
Chloroformi .....℥i
M. Make a saturated solution.

The areas are painted over with this till well coated with a film of chrysarobin, the chloroform rapidly evaporating. Over this is then painted three or four layers of good collodion. The plain collodion is a little too brittle, and the flexible collodion scarcely compressible enough; a mixture of equal parts is more satisfactory. In eight or ten hours the collodion is again applied. No further application is to be made till the film so formed begins to crack or break way or begins to loosen, which it usually does in two to four or five days. It is usually loosened by the growing hairs beneath. As soon as it becomes detachable it is gently pulled off, and if there is any active irritation beneath, a mild ointment may be used for a few hours or a day, till this is subdued. If there is any sign of stumps or growing hairs, the depilatory is again to be used, and the paintings with the chrysarobin and collodion resumed. This plan is to be continued, as with the plan with the iodin paintings, till the disease is finally cured. In some instances, but if used with care not in many, a mild or moderately severe dermatis of the surrounding skin may be set up, and under these circumstances it becomes necessary to suspend the remedy temporarily. In rare instances this tendency to dermatitis may repeat itself, the skin of the patient being intolerant to chrysarobin, and it must be set aside and give place to another plan. Such idiosyncrasy is, however, rare. If the patient or attendant is careless, some of the chrysarobin may be carried to the face or eye and a temporary disturbance of these parts brought about. This rarely happens, however, with the chrysarobin treatment as here advised, as the remedy is kept covered with the collodion film. In addition, it is advisable to have the patient wear a lining of paper or other material in the hat, which will admit of frequent washing or destruction.

In some instances these several methods will fail to bring about a cure: or more frequently will cure most of the areas, but fail to make sufficient impression upon a few patches. It is just in such instances especially that croton oil has its particular field of usefulness, a plan of treatment warmly commended by Alder Smith. In those cases, too, in which there are throughout but two or three patches, and in which for various reasons a rapid cure is desired, recourse may be had to this application. It is a severe remedy, and the parts are made actively inflammatory. Indeed, the object in view is to bring about an artificial kerion—a somewhat boggy and pustular inflammation, which upon abatement usually results in the cure of the patch. In such cases as here mentioned the application is most valuable, and while it may in some instances destroy groups of a few follicles here and there in the areas thus treated, the subsequent growth of hair covers up these small points of baldness completely, so that this possibility is practically of no importance. The careless use of the remedy and the pushing of the inflammatory action beyond a reasonable limit would, of course, result in considerable follicular destruction, and should be guarded against. If carelessly used or its application be unnecessarily long continued, complete baldness of the area could result, but this has never occurred in my experience; and it seems to me that such disaster could only be from gross carelessness, or possibly from some idiosyncrasy of the patient's skin. The scalp will fortunately stand a good deal of even reckless treatment, and yet finally show but little trace of it. Croton oil is, however, a strong remedy, and must always be used with caution. For this reason it is never to be employed in very young children. The general scalp is to be looked after in the same manner as when other methods are used. With croton-oil applications the use of the depilatory may be omitted. At first it is desirable to apply the oil weakened with two or three parts of almond oil, and if it is found that no active inflammation arises, it should be applied stronger. In most cases the pure oil is required. It should be scantily used, as the oil seems to have a distinct tendency to spread beyond the part to which it is applied. It is to be applied two or three times daily, and to bring about the desired amount of inflammatory reaction usually two to six days are required. When it is possible to have poultices repeatedly applied, the oil applications may be discontinued as soon as slight swelling and minute pustulation present; the subsequent poulticing will bring about sufficiently pronounced inflammation. In most cases, however, I have continued the oil applications till this end was reached and then applied boric acid ointment till the inflammation subsided. This ointment or the mild sulphur naphthol ointment can then be used till the new hairs appear, and then all applications be discontinued; at the end of several days or a week the parts and new growing hairs are examined. If there are still signs of the disease the same method is to be repeated. One should be sure, however, that there is still disease there, before resuming the treatment. If the inflammatory action and pustulation have been of sufficiently high grade, a repetition is not usually necessary. If there are several patches to be treated, not more than one if a large one, or two if small, should be treated at one time with the oil. As soon, however, as the inflammation has subsided a new area can be attacked.

In some cases of scalp ringworm the disease is disseminated—disseminated ringworm of the scalp—consisting of scattered small-sized areas presenting five to ten diseased hair or hair stumps. Such cases can be treated by either of the three active methods—iodin paintings, chrysarobin or croton oil. If the spots are numerous the number should be brought down and then, if necessary for final cure, the oil be employed to the remaining areas. In such cases many of the areas yield readily with any good treatment, leaving behind six or more obstinate spots. In those instances of scalp ringworm in which the disease is so extensive as to practically involve the greater part of the scalp, presenting large and irregular areas, it is advisable to use the stronger sulphur naphthol ointment till the disease is reduced in extent. Or this plan can be used, and a small part treated with the iodin or chrysarobin paintings. Croton oil, if finally required, should be left till the disease is brought down to several circumscribed areas; it is never to be used in the beginning of treatment in these confluent cases, nor should it in fact be applied to an area more than two inches in diameter, at the very most.

The several plans here outlined can also be used with advantage in private practice and with intelligent patients of the dispensary class—in the latter excepting, however, the croton oil applications; this even with private cases must be used with caution, and its action daily inspected.

Cheifez reports the cure of two cases of dropsy by massage, applied for 12 to 15 minutes, 6 times in one case and 17 in the other. Massage is commenced at the feet and worked upward.

YALE IN MEDICINE.

At the recent two-hundredth anniversary of the founding of Yale College medicine was represented, and most acceptably so, by Professor Welch of Baltimore, himself a Yale alumnus, who delivered an interesting and scholarly address on "The Relation of Yale to Medicine."[1] Naturally the address is of an historical character. It covers the ground as thoroughly as the time would permit and constitutes a valuable addition to the history of medicine in America. Yale is related to medicine through its medical school and also through those who, having received their general education there, "subsequently practiced the art or cultivated the science of medicine." The Yale medical school was not established until one hundred years after the foundation of the college, and Professor Welch sketches in an interesting manner the position and work of the Yale graduates of the eighteenth century who became physicians, and whose success indicates that they had been so trained in mind and character as to be fitted well for their work.

The long line of over 2300 physicians who have received their liberal or professional education at Yale College is headed by Jared Eliot of the class of 1706. Like many other physicians of his day, Jared Eliot combined the offices of clergyman and physician; "for forty years he never omitted preaching either at home or abroad, on the Lord's day," at the same time as he was "unquestionably the first physician of his day in Connecticut." Of the five medical signers of the Declaration of Independence, two were graduates of Yale, Oliver Wolcott, governor of Connecticut, and Lyman Hall, the first governor of the independent State of Georgia. Now that the organization of the state and local societies is being pushed with renewed vigor, the pioneer work of organization of the medical profession by the physicians of Connecticut, beginning with the oldest existing medical society in this country, namely, the Litchfield County Medical Society, founded in 1765, is of especial interest. The charter of the Connecticut Medical Society is a model one even now. In this important work of organization Yale men took a prominent part. According to Welch, the most valuable published contributions of the eighteenth century by Yale graduates did not emanate from a physician, but from Noah Webster of the class of 1778, whose epidemiological writings have a permanent value. His presentation of the theory of fever is also noteworthy.

In the early years of the nineteenth century the Medical Department was established under circumstances wholly unique in the history of medical schools, the initiative coming from the college, and a compact being entered in with the Connecticut Medical Society, whose charter gave it control of the medical education in the state. By the terms of the union the society agreed to share some of its chartered privileges with Yale College, and in 1810 the Medical Institution of Yale College was incorporated, the sixth medical school of the United States. Of the first faculty the most distinguished member was Nathan Smith, whose fame has steadily increased as his profound influence upon medical and surgical practice in this country has become fully recognized. His essays on typhus fever (typhoid fever) and on the Pathology and Treatment of Necrosis are both classical and far ahead of his time, the profession having slowly caught up with the views there advanced. A graduate of Harvard Medical School, much of his most important work was done in New Haven (1813-1829). Nathan Smith is one of the most attractive figures in the history of medicine in this country, and the profession in general should be made more generally familiar than at present with his life and work.

The Yale Medical Department has taken an important part in the movements to advance medical education, and the work of the Sheffield Scientific Schoool in organizing a distinctive, pre-medical biological course, constitutes one of the most important departures in the collegiate education of our physicians. The preparatory and research work of the Laboratory of Physiological Chemistry under Professor Chittenden long ago placed it among the best laboratories of its kind. Among the more than 2000 Yale physicians of the nineteenth century are many famous names, and "the graduates of Yale in the medical profession have contributed their full share to the making of the medical history of this country." The influence of the work of Professor Welch himself as a teacher and investigator entitles Yale to the gratitude and respect of the medical profession. Surely all will join with the medical sons of Yale in the hearty wish that the present meager endowment of its medical school soon may be increased so as to add still more than in the past to the usefulness and fame of this great university.

THE PATHOGENESIS OF GASTRIC ULCER.

The marked chronicity and limitation to certain geographical regions no less than the peculiar conformation and obscure origin have maintained a singular interest in the so-called round or peptic ulcer of the stomach and duodenum.

In certain localities it is claimed that cases of this nature are increasing. Recent statistics from St. Thomas' Hospital, London, speak for such a condition there, and Greenough and Joslin, who in 1899 summar-

ized the cases of the Massachusetts General Hospital, concluded that gastric ulcer was observed with greater frequency in Boston than in some other large American cities. The importance to surgeons of gastric and duodenal ulcers of this type has increased with the perfected technic by means of which perforation may be successfully combated and various operations to cure or remove the ulcers have been attempted, but as yet with rather meager results.

However interesting these phases, it has been the method of origin of these ulcers that especially has attracted investigators. In animals, gastric ulcers have been repeatedly produced experimentally and sometimes unexpectedly.[1] They have been produced designedly by embolism of the gastric vessels, ligation of the radicles of the portal vein, irritation of the pneumogastric, injury of different parts of the nervous system, by trauma to the epigastric region, and in other manners. The ulcers formed experimentally have, however, failed to simulate "round ulcers" of the stomach; their course has been more acute, they have been multiple or have differed in other respects. The inability to produce round ulcers in animals has consequently not thrown any light upon the etiology of the lesions in man. Among the causes supposed to operate, antecedent localized injury or impaired nutrition and the digestive action of the gastric juice have occupied prominent places. Localized interference with the circulation, trauma, and the action of bacterial or non-bacterial toxins have been advanced to account for the preliminary injury; these explanations, however, omit to elucidate the marked prefereuce of round ulcer for the pyloric region, its round or punched-out character, its extreme chronicity and the fact that it is usually solitary; as for the hyperchlorhydria theory of Riegel, it has been quite generally abandoned.

It seems that the final proof of at least one mode of genesis has been furnished by Yzeren.[2] By section of the vagus below the diaphragm, he was able to produce gastric ulcers in rabbits that were usually single, occurred in the pyloric region and lasted in some instances many months. As is well known, cervical vagotomy, although unilateral, jeopardizes the life of an animal, but Palow showed that with sections below the distribution to the important thoracic viscera, not only will the animal live, but the secretion of the gastric juice is not materially interfered with. In laparotomized rabbits and dogs, Yzeren studied the movements of the stomach, estimated its muscular tonus, the intragastric pressure, and the influence of the vagus upon these activities. He concluded that although there are inhibitory—sympathetic—fibers in the vagus, it is essentially motor. A few days after the vagotomy the stomach becomes smaller and harder; the pressure within the organ is greater and the muscles maintain a fairly continuous tonic contraction. In nine of twenty rabbits that were allowed to live more than two weeks after vagotomy, ulcers were demonstrated; in one animal the ulcer was found over nine months after vagotomy. In all cases the ulcers developed in the pyloric region on or near the lesser curvature; in all except one case the ulcer was single; in one rabbit death took place by perforation. Yzeren likens these ulcers to those of decubitus, as occur for example with chronic myelitis; in the stomach the pressure upon the vessels of certain regions is caused by tonic spasm of the musculature, this in turn results from the loss of the innervation of inhibitory fibers.

There are some attractive points to the theories of Yzeren; the election of certain sites is explained as well as the occasional development of gastric ulcer following severe attacks of vomiting; it is not unlikely that degenerative changes in the vagus in chlorosis might act as vagotomy does in animals. To account for gastric ulcers by muscular contraction is not altogether novel, for Talma in 1899 claimed that cramps in the stomach were in some way connected with gastric ulcer; others, too, have noticed this association. Yzeren has failed to notice the work of the Italian Saitta,[3] who obtained multiple ulcers in the stomachs of rabbits by bilateral vagotomy and administration of HCl.

New researches directed to the discovery of serious alterations of the vagi in chlorosis and other forms of anemia are needed, and these nerves should be thoroughly examined in cases of round ulcer that come to necropsy. The effect of such investigations as these upon the therapy of gastric ulcer can not be foretold; they will certainly lead to more intelligent treatment. Yzeren found that an extra-mucous slitting of the muscular coats in vagotomized rabbits was seldom followed by ulcer; and in man gastro-enterostomy is usually followed by healing of the ulcer.

THE PATHOLOGY OF BURNS.

Extensive burns of the surface of the body have a practical interest and have been the subject of much theoretical and experimental work. But in spite of extensive investigation there is still no unanimity of opinion as to the exact mode of death in many of these cases. The initial shock, broncho-pneumonia, secondary sepsis and hemorrhage from ulcer of the duodenum explain the fatal termination in some instances. Yet there still is lacking a clear understanding of the pathologic processes involved in many of these mysterious cases.

F. A. Hoffman[1] calls attention to the fact that while there has been much experiment and hypothesis concerning this subject there is still a remarkable lack of that which is the true groundwork of the whole matter, viz., a collection of good clinical histories and records of complete autopsies. With these thoughts in mind, M. Wilms,[2] of the surgical clinic of Leipzig, has worked on

1. Constitutional Diseases.
2. Mittheilungen aus den Grenzgebieten der Medizin und Chirurgie. Band viii, Hefte 4 und 5.
3. Gaz. degli Ospedali (Milan), 1900, xxi, 599.

this subject largely from the clinical standpoint, and while his conclusions are not beyond criticism, as he himself admits, his work deserves more than passing notice, if for no other reason, because he proposes a simple therapeutic measure which he believes is of great value.

Wilms dismisses most of the theories already advanced to explain the phenomena of burns as wholly unsatisfactory. The nervous and reflex theory of Sonnenburg has no clinical support from an examination of blood pressure and vasomotor disturbances. Nor do clinical observations bear out the theory of wholesale destruction of red blood corpuscles. The hemoglobin quickly disappears from the urine and blood counts often show more than the normal number of erythrocytes to the cubic millimeter. Nor does he find confirmation of the theory that the remaining corpuscles are so injured as to be unable to perform their functions, or that the liver, spleen and kidney are seriously damaged by the destroyed or altered blood corpuscles. The kidneys may be incompetent, not so much through the absolute increase in the hemoglobin that mechanically obstructs them as through the poverty of the blood in plasma, a large amount being lost through the burned skin. In this way the kidneys are not flushed as they should be. Relative anuria may thus result. A nephritis may occur preceded, and followed, by an albumosuria. The albumose Wilms thinks is the cause of the nephritis with its albumin and casts. The lessened coagulability of the blood and the failure to find numerous thromboses make him question the theory that the blood-plates in cases of burns are greatly increased in number and lead to multiple thromboses.

As stated above, the loss of water, or rather plasma, from the blood is considerable where burns are extensive and not too deep. Of this the formation of blisters and the quickly soaked dressings give ample proof; and Wilms has by measurement of water ingested and water eliminated by the kidneys, shown that this loss of plasma is greater than one would suppose, greater even than in cholera, as Tappeiner[3] showed in 1881. The small amount of plasma in the vessels accounts for the relative richness of the blood in corpuscles and for the anuria. The blood, in a word, is concentrated. In order to avoid this condition as much as possible Wilms has given huge quantities of water, tea, coffee or light beer to his patients and, as he believes, with good results. The concentration of the blood is lessened, the kidneys are flushed and mechanical obstruction diminished, and with the increased amount of urine toxic substances are more rapidly eliminated.

That toxic substances may result from extensive burns and that their presence in the circulating blood may produce a deleterious effect has been often referred to by other writers. Wilms, from the finding of albumose in the urine, believes the toxic substance is a product of the destructive splitting up of albumin in the tissues in the immediate neighborhood of the burn, that this toxic material accounts for the fever, the pulse changes, the vomiting, the collapse, the nephritis. It is eliminated as albumose, though what preceding chemical changes take place is uncertain. This toxemia is found especially in burns of the third degree, where the skin is charred and leathery and exudation on the surface does not take place. In these two conditions of the blood—its poverty in plasma and its richness in toxic material—Wilms sees an explanation, or at least a partial explanation, of the phenomena of burns. His work is suggestive and should lead to more careful clinical observation, including examinations of the urine and of the blood. His treatment—the administration of large amounts of water by the mouth, rectum and under the skin—is harmless and appeals to one as having a rational basis.

A VISITOR'S OBSERVATIONS.

In the November issue of the *Practitioner* its editor, Dr. Malcolm Morris, records some of the impressions he received during his recent visit to this country as the Lane lecturer at the Cooper Medical College in San Francisco. He says some pleasant things about the earnestness he observed in the medical schools visited, especially mentioning the Cooper Medical College, the medical department of the University of California, the Johns Hopkins, and the colleges of Philadelphia and New York. He says: "A European observer feels that Professor Osler's dream that at the end of this century ardent Old World students may go to the other side 'as o'er a brook,' seeking inspiration from great masters, may easily be fulfilled." He goes on to state that even at present they might do worse than go to the places mentioned, "for at all of them post-graduate instruction is to be had, which for quality, variety and excellence could scarcely be equaled in any European country." It is pleasant to thus have our good points appreciated by the intelligent foreigner, but it need not make us unduly elated. We can certainly show him a variety in our medical educational institutions and a few that the old world can not excel.

OHIO SOCIETY FOR PREVENTION OF TUBERCULOSIS.

Our news columns contain the announcement of the formation in Ohio of a state society for the prevention of tuberculosis. This is an encouraging sign. While health boards, medical societies and individual members of the medical profession have done much to limit the propagation of tuberculosis, such a society as this one in Ohio will be a big help in the work, from the fact that laymen of large political influence have been induced to take active part by assuming some of the important offices. The society is to be congratulated for having secured the coöperation of these gentlemen, not only because by this means the public at large will become interested, but also because to carry on the work of the society considerable money will be needed, which a purely medical society would not be able to obtain, working alone. So far as formulated, the plans of the society include the establishment of a state hospital for consumptives in whom there is a chance of cure, and the

isolation as far as possible of incurable cases in smaller hospitals in different parts of the state. If the plan can be carried out the greatest good can be accomplished. It is to be hoped that this action in Ohio will be followed by similar action in other states.

AMERICAN JOURNAL OF ANATOMY.

Among the many new journals that have been offered to the profession in this country during the last few years, none has appeared that is more deserving of high praise than the *American Journal of Anatomy*. The initial number, which has just been received, is another evidence of the high-class work that is now being done in this country in the less utilitarian departments of medical science. Activity in ultra-scientific medical work and investigation was never greater than at present, and American investigators are becoming as active and as numerous as are those in any European country. There are many indications that European scientific workers will soon be looking this way to find some of the best original work in the purely scientific as well as in the practical department of medicine and the appearance of this journal is one of them. The scientific contributions contained in it are of the highest order of merit, and its excellence from a mechanical point of view deserves the warmest praise. There has evidently been a determination not to see how cheap the journal could be put out, but how good it could be made. The illustrations are superb, and especially is this true of the plates. It will be published quarterly at five dollars per annum. We understand that a number of generous medical men have backed the enterprise with financial support, so that its future is guaranteed. But it is one of those enterprises that deserves the support of all who are interested in scientific medicine, whether their work lies in the particular branch which this journal represents or not. It is naturally only of direct interest to but few, but indirectly it is of interest and advantage to all who have the welfare of scientific medicine at heart. The editors are Professors Barker of the University of Chicago, Dwight of Harvard, Gage of Cornell, Huber of Michigan, Huntington of Columbia, Mall of Johns Hopkins, Minot of Harvard, and Piersol of the University of Pennsylvania. The list of those who have promised to contribute contains the names of representative men in the profession.

INTOXICATION WITH BISMUTH.

The general impression prevails that when symptoms of poisoning arise in connection with the administration of bismuth or its combinations the manifestations are due to the presence of impurities, the most important of which is thought to be arsenic. Evidence is not wanting, however, tending to show that uncontaminated bismuth may give rise to toxic effects, which in some respects resemble those due to lead and mercury. A number of such instances are cited in a brief communication by Dr. Dreesmann,[1] who also reports a case under his own observation. Thus, following the dressing of wounds and wound cavities with bismuth subnitrate and other preparations of bismuth, as well as the internal administration of large amounts, there has been observed in the urine a white precipitate, becoming black, together with albumin and tube casts, stomatitis, pain in and loosening of the teeth, a metallic taste, with a blue line on the gums, and dark discoloration of the tongue, diarrhea, and pigmentation and ulceration of the intestinal tract, especially the large bowel. It has been shown experimentally that pure bismuth introduced into the pleural or peritoneal cavity is capable of exciting adhesive inflammation, and even perforation. The case of Dr. Dreesmann occurred in a man 30 years old, who had been quite severely burned and was treated with local applications twice daily of a 10 per cent. ointment of bismuth subnitrate. In the course of three weeks a black sediment was noted in the urine. In the course of three weeks more marked stomatitis developed, with pain and difficulty in swallowing. The teeth became loose and a bluish-black line appeared at the margin of the gums. Similar discoloration appeared also on the tongue. An area of ulceration resulting from the burn also exhibited black pigmentation, which disappeared but gradually. The preparation employed was free from contamination, particularly lead, and the symptoms could be attributed only to the bismuth. Improvement ensued as soon as a boric acid ointment was substituted for that of bismuth. From all of the evidence it would thus appear that bismuth, both applied topically and administered internally, is susceptible of absorption, and capable of giving rise to toxic manifestations, consisting principally in irritation of the digestive and the urinary tract; accordingly, some care should be exercised in the employment of this useful drug, which is generally considered entirely innocuous.

1. Berliner Klin. Wochenschrift, 1901, No. 36, p. 94.

SEASICKNESS.

Seasickness is a distressing disorder from which a large proportion of the traveling public suffer; yet it hardly receives mention in works on practice. Its pathology is still a matter for discussion among medical authorities, and now come the naval architects with their theories of its causation. Any one who has had experience knows that steamers are much more conducive to this distressing ailment than sailing ships, and the difference is chiefly attributed to the lack of steadying effect of the wind and consequent unregulated rolling and generally exaggerated motor performance of the vessel. With the increase of size of ocean packets of late years, this cause ought to be somewhat restricted, but according to the scientific shipbuilders a new element is introduced. A long vessel is practically a vibratory bar with its nodes and loops, and the longer the ship and the greater the speed and power of the engines, the more pronounced is the vibration. When the engines of the ship in their action strike the proper note of the structure and work in unison, then it is that the vibrations are greatest, and though the vessel may be running through quiet seas, a score or more of the passengers before unaffected may have to succumb to the sickness of the sea. The seasickness in this case is, therefore, according to the explanation, an effect of a quasi-musical phenomenon; it is a pathologic discord of the

nervous and digestive systems with the vibratory note of the ship, or a special fatigue resulting from the rapid succession of minor shocks. It is aggravated, moreover, according to the naval architects, by the exaggeration of the movement of a spring mattress so that when recumbent the discomfort may be even increased. Heretofore we have not seen so much importance attributed to merely vibratory motion in the production of seasickness, and while it is possible that it may have its part, this is doubtful; still some persons are subject to "car sickness" in railroad travel which may be due to this cause, and similarly sensitive individuals would probably suffer in sea travel, all the more because with it would be combined the pitching and rolling movement that usually causes seasickness. To this latter we must still attribute the greater part of the victims, but the explanation above offered has still a certain interest though not valid for the majority.

MODERATE DRINKING AND TOTAL ABSTINENCE.

Dr. Dyce Duckworth has lately emitted some views in regard to alcoholic drinking, in an address before a congress of medical examiners at Amsterdam, that seem hardly to agree with the accepted views of life-insurance authorities in this country. He maintains that total abstinence is undesirable in an insurance point of view; in fact, that it would be better for everyone to indulge moderately to just the right amount. He admits that even a slight excess is harmful, and he would not advise the daily use of as much as, what he puts as the physiologic dose, two ounces of alcohol. Yet he believes alcohol to be a food and a valuable element in the daily diet. He also admits that total abstinence is better than any, even the least, misuse. Careless persons with unstable nervous systems and of lower animal nature may, he says, practice total abstinence, but sensible people who can control themselves need not; indeed, he goes further and says he believes that the lives of truly moderate drinkers of alcohol are probably on the whole better and more useful than those of abstainers. The weak point in his argument is that he offers nothing but his own authority for all he says, and bases his opinion only on his personal general observation and experience. There should be something more than this in view of the many careful observations, the contradictory experience of so many others, and the accurate experimental studies of such men as Kraepelin and others. To say that moderate drinkers lead better and more useful lives than total abstainers is a little strong, even admitting that some of the latter are cranky and extreme in their views. Insurance experience, in this country at least, does not prove that they are better lives in one sense. There seems to be a difficulty to the average man in walking in the straight and narrow way of moderate drinking that he advocates, and our insurance statistics show a rather better record as regards mortality for abstainers than for the other class. Dr. Duckworth evidently appreciates this weak point, for he says he offers no statistics to prove his contentions and has long since learned to distrust them. Actuaries' figures, however, will probably still continue to govern the policy of insurance companies rather than the personal views of even so eminent a practitioner as Sir Dyce Duckworth. One may reasonably doubt whether figures lie in this case.

UNJUSTIFIABLE DISTRUST IN DIPHTHERIA ANTITOXIN.

An extract from the "Weekly Bulletin" of the Chicago Health Department in the Medical News section of this issue shows that the worst forebodings of the Journal[1] as to the serious and far-reaching results of the recent deplorable occurrence in St. Louis are being fully realized. An increase of one-third in the case mortality of diphtheria since the first of the month is attributed to a growing distrust of antitoxin. The medical inspectors and antitoxin administrators of the department report that parents refuse to allow the use of antitoxin unless the physician will pledge himself that the serum is perfectly pure and free from any danger of causing tetanus. Even then in many cases its use is positively forbidden. Fortunately, the department men are able to give such pledge unhesitatingly. All antitoxin used or distributed by the department is tested—not primarily for its freedom from any pathogenic properties, but for its antitoxic strength. Out of each instalment received in the laboratory 5 per cent. is tested on guinea-pigs previously injected with diphtheria toxin; if the animals survive without untoward symptoms or undue reaction the instalment is accepted as of the the antitoxic strength indicated on the label of the package. Obviously, if the serum contained the tetanus bacillus or other pathogenic germ, that fact would be developed in this test. No such result has ever followed during the six years' use of this remedy by the department, but on three occasions instalments have been rejected for failure of the indicated antitoxic strength. The test is so simple and so conclusive that the practice should be uniformly adopted. If necessary, legislation should be had forbidding the sale or use of any antitoxin not thus tested and certified by some competent authority. It is said above that "fortunately the department men are able" to pledge the purity of the serum they use. Unfortunately, this is not the case with the private physician, who, it is reported, very often shrugs his shoulders and replies to the anxious query of the parent: "I can not guarantee anything; you must take your chances!" Is not this a cowardly attitude for a medical man? Is it not his duty to know positively the properties and the qualities of the remedies he offers to use? He can guarantee this as well as any other remedy he uses, and should hold the producer responsible in this case as he does the druggist who puts up his prescriptions. The evidence so far given points to a fatal but avoidable mistake as a cause of the St. Louis tetanus cases, and the result will be all the greater care and greater safety in the manufacture and use of antitoxin hereafter. A 33 per cent. increase in the case mortality of such a tractable disease as diphtheria under the antitoxin treatment within less than three weeks is too serious a matter to be dismissed with a shrug of the shoulders. The baker's dozen of tetanus deaths in St. Louis sink into positive insignificance compared with the untold thousands of avoidable diphtheria deaths which will inev-

1. See pages 1255, 1323.

itably follow unless members of the medical profession demand a guaranteed purity of antitoxin and are thus enabled to speak with the confidence of definite knowledge and so inspire the anxious parent with their own confidence. The producers of antitoxin themselves, in their own interests, should lose no time in securing such a test and guarantee.

Medical News.

CONNECTICUT.

X-Ray Damages.—Dr. John Weldon, Willimantic, has recovered $6750 damages from a firm in Boston who sold him an *x*-ray machine from which he received a burn incapacitating him from work for twenty-two months.

Scarlet fever is reported to be prevalent in the towns around New Haven. The school at North Branford has been closed; Centerville has six cases, and twelve cases are reported in the Union Hill school district in Union City. Several cases are reported from Meriden.

Memorial to Dr. Hudson.—A special meeting of the Hartford Medical Society was held October 31 to take action on the death of Dr. William M. Hudson, vice-president of the Society. Addresses were made and a committee was appointed to draw up resolutions of respect for his memory.

FLORIDA.

Personal.—Dr. Ned C. Berry, formerly house surgeon in the Plant System Hospital, Sanford, has located in Kissimmee City.——Dr. Richard H. Gillen, De Land, has moved to Seattle, Wash.——Dr. O. S. Whipp, Braidentown, has moved to Clearwater.——Dr. Theodore Turnbull, Monticello, has moved to Jacksonville.

ILLINOIS.

Will County Medical Society met at Joliet, November 12. The address of the evening was delivered by Dr. E. C. Dudley, of Chicago, who reviewed the history and development of hysterectomy and myomectomy for uterine myoma.

Must be Vaccinated.—The Mt. Sterling Board of Health promulgated an order, November 12, that all persons be vaccinated. Those unable to pay will be vaccinated at the expense of the county, provided the fee does not exceed 25 cents.

City Wins Suit.—Du Quoin brought suit against Perry County for expenses incurred in caring for smallpox patients in the isolation hospital and elsewhere. The case went to the Supreme court, which has now decided in favor of the plaintiff.

Diphtheria.—Two schools in Greenwood township, Christian County, have been closed on account of the disease.——Joliet reports one case.——At St. Viateur's College, Bourbonnais Grove, three students are ill with the disease.——Rockford has two new cases.——Eight cases are reported from Cornell.

Personal.—Dr. Robert E. McClelland, Williamsville, who has been ill a long time, has secured Dr. Claude A. Lloyd, Chicago, to take charge of his practice.——Dr. Abraham L. Miller, Dixon, has been elected a member of the board of trustees of Carthage College.——Dr. Charles M. Galbraith, late surgeon of the 47th U. S. Volunteers, has returned from the Philippine Islands and will resume practice in Carbondale.

Smallpox.—Trouble has arisen in Springfield because the mayor has established an isolation hospital in Oak Ridge Park. Thirty cases in all have been reported in the city.——Grafton has the puzzling disease which looks like, but is said not to be, smallpox.——The prevalence of the disease at Hamilton, where 20 cases have been reported, has caused Nauvoo to issue a proclamation establishing a quarantine.——Strawn has several cases of the disease.——Peoria reports 15 cases, and Elverton and Athens have each one.

Chicago.

Smallpox.—During the past week four cases of smallpox have been discovered in the city.

Personal.—Dr. Charles Edward Manierre has returned to Chicago and resumed practice at 552 La Salle avenue.——Dr. F. H. Russell has located in Kewanee, Ill.

Norwegian Lutheran Hospital.—Contracts have been let for the construction of a hospital for the Norwegian Lutheran Deaconess Society, to comprise several buildings from one to three stories in height and to cost $40,000.

Contagious Disease Hospital.—Plans for a hospital where contagious and infectious diseases will be exclusively treated are on foot, and for the purpose of giving information and collecting funds an office has been opened in room 132 Hartford Building. A charter for such a hospital has already been obtained. The necessity for such an institution is urgent.

Influenza Threatens.—Although the mortality rate for last week was satisfactorily low—12.35 per 1000 of population—the outlook for the immediate future is not reassuring, says the Department of Health. Influenza threatens seriously; there was an increase of fully 30 per cent. in the finding of grip germs in the laboratory examinations. The presence of the pneumonia germ also markedly increased.

Distrust Antitoxin.—An increase of fully one-third in the number of deaths from diphtheria in proportion to the number of cases reported is noted during the past fortnight. The medical inspectors of the department report a distrust of the use of antitoxin, both by physicians and parents, which fully accounts for this result. Such distrust is, in the judgment of the Commissioner of Health, wholly unwarrantable. He says: "Probably never before in the history of antitoxin has this specific for diphtheria been so safe to use. The deplorable results in a neighboring city furnish no criterion of the method of antitoxin production in general, and the fact that more than 140,000 injections of the remedy distributed by this department during the past six years without a single such result should reassure those who have been needlessly alarmed."

INDIANA.

Smallpox has appeared at Lafayette, where two cases are reported, and at Castleton, where a small epidemic has occurred in which three patients have died.

Smallpox Risks.—The Secretary of the State Board of Health reports that the conditions all over the state indicate that there will be more smallpox than ever before and urges on the health authorities and the people the necessity of taking preventive measures at once.

Personal.—Dr. George D. Baily has purchased the interest of Daniel J. Mitchell in the Spiceland Sanatorium.——Dr. Cory R. Per Due, Etna Green, has sold his property to Dr. H. E. Crockett, Lafayette, and will move to New York City.——Dr. Oscar Heller, New Palestine, coroner of Hancock County, has resigned and Dr. Noble P. Howard, Jr., Greenfield, has been appointed to fill the vacancy.

Blacklist Debtors.—The Physicians' Protective Association of Elwood has prepared a blacklist, containing the names of families who have run bills with one physician, and when their credit was exhausted, called in another. The physicians will refuse to answer calls from any of them. Their laws are said to impose a fine of $5 on any physician who makes a professional call on a family on the blacklist, and a fine of $25 for the second offense. Every physician in the city is said to belong to the association.

IOWA.

Personal.—Dr. Edwin J. Moffitt, Jesup, has moved to Topeka, Kan., where he has a hospital appointment.——Dr. Charles E. Todd, Oskaloosa, has moved to Los Angeles, Cal. ——Dr. Ridenour, Raymond, has located in Jesup.

Physician Found Guilty of Murder.—The proprietor of the Crofford Sanatorium, Leon, on November 16, was found guilty of murder in the second degree on account of his complicity in the death of an inmate of the institution.

Farewell Dinner to Dr. Sawyers.—The Centerville Medical Society gave a dinner, November 1, in honor of Dr. John L. Sawyers, who is about to leave the city. The address of the evening was given by Dr. Ephraim M. Reynolds. Resolutions were passed regretting the removal of Dr. Sawyers.

St. Luke's Medical Board.—The trustees of St. Luke's Hospital, Davenport, have selected the following medical board for the ensuing year: Attending staff, in surgery, Drs. William L. Allen, Henry U. Braunlich, and Richard W. Hill; in gynecology, Drs. J. P. Crawford and Alphons L. Hageboeck; in obstetrics, Drs. John A. De Armand and Edward F. Strohbehn; in medicine, Drs. Edward S. Bowman, George E. Decker, Frederick Lambach and Bernhard H. Schmidt; in nervous diseases, Dr. Jennie McCowen; in ophthalmology, Dr. Albert W. Elmer; in oto-laryngology, Drs. George W. Banning and Karl Vollmer. The consulting staff consists of Drs. William

D. Middleton, Lucius French, H. Matthey, Carl Matthey, J. W. H. Baker, and John H. Kulp.

KENTUCKY.

Typhoid fever is epidemic at Corrishville and Dugansville, Mercer County.

Smallpox.—Paducah has two cases.——Three cases have appeared in the Story's Branch neighborhood, Fleming County.——All the schools in the neighborhood of Craigs and Foothill, Bath County, have been closed on account of the disease.

Diphtheria has broken out in severe form in the northeastern part of Mercer County. On account of the prevalence throughout the state, the State Board of Health has issued a circular on the prevention of the disease, addressed to health officials and the general public.

Personal.—Dr. Edward M. Green, Versailles, has been appointed to the staff of the Georgia Sanatorium for the Insane, Milledgeville.——Dr. Vaudois E. Handley, Sturgis, has decided to move to California.——Dr. Charles W. Aitkin, Flemingsburg, has located in Lexington.——Dr. George Jean, Danville, has passed the examination of the medical department of the Army, and is ordered to the Army Medical School at Washington, D. C.——Major W. W. Gray, surgeon, U. S. Army, has succeeded Major William O. Owen, as surgeon at Fort Thomas.

LOUISIANA.

Physicians Fined.—For failure to furnish vital reports to the health authorities as required by law, eighteen physicians and one midwife of Acadia were fined $5 each, November 11.

The New Orleans Polyclinic opened, November 4, with a good class. The great clinical advantages offered by the city, combined with the mild climate, make it a desirable place for the medical profession in winter.

Dr. Brickell Honored.—Dr. William E. Brickell, who has been physician to St. Vincent's Orphan Asylum, New Orleans, for twenty-five years, was tendered a tribute of love and appreciation in the shape of an entertainment at the institution, November 7, at the close of which he was presented with a silver smoking set.

Personal.—Dr. Arthur W. de Roaldes, founder of the Eye, Ear, Nose and Throat Hospital in New Orleans, who spent the summer in Europe, has returned.——Dr. Edmond Souchon, New Orleans, returned November 7, from a trip through Mexico.——Dr. Latzi L. Szabary, Third District, New Orleans, has leased the Beauregard place, and will reside in St. Bernard parish.——Dr. William Kohlmann, New Orleans, has been appointed surgeon to the Touro Infirmary, vice Dr. Frederick Loeber, Jr., deceased.

MARYLAND.

Dr. Albert C. Reuling, Baltimore, has returned from Europe.

Deaths in Baltimore.—There were 156 deaths in the week ended November 16; 14 were from pneumonia, 3 from diphtheria and 2 from typhoid fever.

An orthopedic department has been added to the City Hospital Dispensary, College of Physicians and Surgeons, and Dr. Albertus Cotton has been placed in charge of it.

The new training school for nurses at St. Joseph's Hospital, Baltimore, was opened November 11. Three years of study are required, with two lectures daily and instruction in the wards. The lectures are delivered by the hospital staff.

Dr. Howard A. Kelly gave a reception to the students of the Baltimore College of Dental Surgery November 11. The affair was in the interest of the Y. M. C. A., and the officers of the association were all present with about 100 students and other guests. Addresses were made by Dr. Kelly and Rev. John T. Stone.

Dr. Lesslie M. Sweetnam, Toronto, Ontario, is at the Johns Hopkins Hospital, being treated for blood poisoning. He scratched the fore-finger of his right hand in operating and it was feared that he would lose his right arm, but Dr. Halstead has tried conservative treatment and the case is progressing well.

Dr. Frank T. Shaw and family, Westminster, were poisoned November 16, by eating oysters which had been fried in a preparation of arsenic and cornmeal, made for rats and left in the pantry. The cook not knowing it contained arsenic used it in frying the oysters. Owing to the burning sensations produced, the family partook but sparingly of the repast and prompt vomiting prevented any fatal results.

MINNESOTA.

Addition to City Hospital.—A permit was secured, November 5, to erect an operating ampitheater, kitchen and laundry in connection with the City Hospital, Minneapolis, at a cost of $35,000.

Personal.—Dr. John B. McNerthney, Delavan, will locate in Tacoma.——Dr. Pence, late physician at the City Hospital, Stillwater, has been appointed assistant physician at the Fergus Falls State Hospital for the Insane.——Dr. Robert A. Campbell, formerly admitting physician at the City Hospital, Minneapolis, has been made resident physician at the institution.

Smallpox.—A member of a theatrical company was seized with smallpox at Luverne and the company is in quarantine in its special car.——The disease is reported at Langdon.——Dr. Robert I. Hubert, St. Cloud, was indicted November 14 for "wrongfully, unlawfully, wilfully failing, neglecting and omitting to report contagious diseases of smallpox to the board of health."

Compulsory Four-Year Course.—The custom heretofore permitted at the State University, of allowing academic students who take a medical course after graduation, one year's credit on their medical course, has been changed, the State Board of Medical Examiners having refused to issue permit to practice to anyone who has not taken a four-year course in a medical school.

Safeguarding Against Blackmail.—Acting under advice from Attorney-General Douglas, Insurance Commissioner Dearth has ruled that, under the laws of Minnesota, general casualty indemnity companies may write contracts, insuring physicians against loss by reason of damage suits arising from the results of their practice upon patients. Such insurance is, however, invalid in case of an operation which is in itself illegal.

MISSOURI.

Personal.—Dr. W. S. Wheeler, Kansas City, has been appointed investigating physician for the Board of Health; salary $150 per month.——Dr. William H. Mook, St. Louis, has been appointed assistant physician at Quarantine.——Dr. W. A. Pendergraft, Elkland, who recently moved to Buffalo, has located in Marshfield.

Fatal Case of Hemophilia.—A case of hemophilia was admitted to the City Hospital, St. Louis, a few days ago and died of hemorrhages from the mucous membranes of the nose and mouth. Postmortem examination revealed general hemorrhages from the mucous membranes, with some increase in the lymphadenoid tissues of the abdominal cavities. A microscopic study of the small arterioles and capillaries is now being made.

Isolation Hospital at St. Joseph.—The Board of Health has introduced an ordinance providing for the immediate erection of a pesthouse at a cost of $1,500. It tacitly agreed to repeal all ordinances providing for public work that could possibly be dispensed with, the funds thus secured to be devoted to meeting Health Department expenses. It resolved to accept no smallpox patients from the county save on payment of $5 a day in advance for maintenance of each patient, in retaliation for the county's refusal to assist the city in erecting a pesthouse.

Coroner Condemns Health Department.—Coroner Funkhouser rendered a verdict November 18 which states: "We find that the decedents came to their death from tetanus, following administration of diphtheria antitoxin containing tetanus toxin, said diphtheria antitoxin having been prepared and issued by the Health Department of the City of St. Louis and bearing dates on labels of Aug. 24 and Sept. 30, 1901. The presence of tetanus toxin in the diphtheria antitoxin shows negligence upon the part of the Health Department in the preparation of said diphtheria antitoxin and in the issuance thereof."

Registration of the Tuberculous.—Much interest has been aroused in St. Louis on account of the proposed legislation regarding tuberculosis. The bill formulated by the Board of Health for action by the City Council classes tuberculosis among the contagious diseases and required that the Board be notified by the attending physician of each case. One section of the bill provides that at the request of any physician the Board shall have the authority to determine the existence of tuberculosis in a suspected case, and shall fumigate the dwelling of such a case once in ninety days if it is thought best. Fines are to be imposed upon physicans failing to report

cases. The St. Louis Medical Society unanimously condemned the bill, believing that the Board of Health should confine its efforts in this direction to educating the people and in making microscopic examinations of the sputum. The only return to the patient from making public his misfortune would be an occasional fumigation which can not be effective. It was asserted that if this measure prevailed it would prevent patients from seeking medical aid in the early stages and defeat the best efforts for limitation of the disease. Education as to cleanliness, thoroughness in the care of the sputum and the disinfection of the utensils used in eating and drinking are more effective than all the so-called disinfection by fumigation. The bill was permanently shelved by the City Council, November 12.

NEBRASKA.

New Licenses.—At its meeting, November 7, the State Board of Health issued certificates to 17 applicants for license to practice medicine in the state.

Wise Memorial Hospital.—This institution, established by a Jewish Society of Omaha, in memory of Rabbi Wise, was opened November 17. It will be conducted on non-sectarian lines and as many free beds as possible will be maintained. Its present capacity is 50 beds. The surgical staff consists of Drs. John E. Summers, August F. Jonas, Byron B. Davis, Charles C. Allison, and Millard Langfeld. The medical staff includes Drs. Oscar S. Hoffman, Paul H. Ludington, Willson O. Bridges, Charles Rosewater and a number of specialists.

Smallpox.—Up to November 7, the physicians throughout the state had reported 600 cases of smallpox.——It was announced that the death rate from the disease among the Winnebago Indians was 10 per cent.——Long Pine has 60 cases. When quarantine was proposed it was found that the state board could recommend, but not enforce regulations. Local boards must protect the health of the community and prevent the spread of the disease.——Cedar and Knox counties have 30 cases of the disease.——Ainsworth has quarantined against Long Pine.——A number of cases have developed at Johnstown and Wood Lake.

NEW JERSEY.

Dr. Daniel Stock, Camden, is seriously ill as the result of an infected wound of the palm of the right hand received while operating.

The new buildings of the New Jersey State Hospital were formally opened November 21 by Governor Vorhees. Among the speakers were Dr. Henry M. Hurd, Baltimore, and Governor-elect Murphy.

Isolation Hospitals.—Two portable hospitals and an administration building contracted for by the Newark Board of Health will be ready for occupany this week. The hospitals are intended for smallpox patients, the number of which is daily increasing and already exceeds the capacity of the present small building used as an isolation hospital.

The Morristown Medical Club, made up of the leading medical men of Morristown and vicinity, was entertained by Dr. H. A. Cossitt at the State Hospital, who presented a paper for discussion on cholelithiasis, and cited three cases that he had recently operated on, with recovery. The November meeting will be led by Dr. Douglas, of Morristown.

Cheap Diploma.—James Norton-Smith, manager of the Central University of Medicine and Science, Jersey City, was arrested, November 16, on a charge of attempting to obtain money by false pretenses. The charge was made by Chief of Police Benjamin F. Murphy and was based on a letter received from Dr. D. H. Harrison, of Swanville, Tex., to whom Norton-Smith had sent a letter offering to furnish a diploma for $10.

Smallpox in Orange.—Six cases have been reported, all in the same house. On November 14 a girl seven months old was taken with smallpox, which was traced to an uncle who had been for three weeks under treatment with doubtful indications including the convalescent stage. At the date mentioned the mother, her three-year-old son, her brother aged 16, and sister aged 13, all had the disease. The house is now under quarantine and stringent precautions have been taken against the spread of the malady.

Staff Changes.—There have been several changes recently in the staff of the New Jersey State Hospital at Morris Plains. Dr. A. S. Corwin, assistant physician, is now serving upon the staff of Hudson Street Hospital, New York City; Dr. H. A. Cossitt was appointed to fill the position; Dr. T. P. Prout, pathologist and second assistant, resigned to pursue pathological studies at Vienna. He has done some original research work in epilepsy during the past year. This vacancy was filled by the promotion of Dr. H. A. Cossitt, and the appointment of Dr. W. H. Barton, of Connecticut, as pathologist and fourth assistant. Dr. C. C. Beling, late of Hospital of Ceylon, and Edinburgh, Scotland, was appointed fifth assistant, and Dr. Raymond D. Baker, of St. Joseph's Hospital, Paterson, sixth assistant physician.

NEW YORK.

Personal.—Dr. John F. Crowley was appointed town physician of Batavia, vice Dr. Lucius B. Parmele, who has gone to California for his health.——Dr. Hardin W. Bright, Niagara Falls, has moved to Ransomville.——Dr. Fred A. Smart, Carlisle, has moved to Nassau.

Chief Surgeon Suspended.—The Board of Trustees of the State Soldiers' and Sailors' Home have suspended Dr. James T. Burdick, surgeon-in-chief of the Home Hospital, pending the charges preferred against him by Col. Andrew Davidson, commandant. There are twenty-four specific charges, one of which is insubordination. Assistant-Surgeon A. P. Sheelman will have charge of the hospital pending the disposition of the charges. Dr. Burdick is a prominent G. A. R. man, being past medical examiner of the Department of New York, and was appointed surgeon in chief, February 22.

Buffalo.

The Gratwick Pathological Laboratory of the University of Buffalo is expected to be finished in a month. All the apparatus of the laboratory, which is now in the University, will then be transferred to the new building. The laboratory building was given the University by Mrs. Gratwick as a memorial to her deceased husband. Dr. Harvey R. Gaylord is in charge of the laboratory.

Magnetic Healer Fined.—William von Scheidt, a magnetic healer, was arraigned in the municipal court charged with violating a rule laid down by the Health Department, which makes it incumbent on physicians and others to report any cases of contagious diseases. Von Scheidt is charged with having failed to report a case which resulted in death from diphtheria. In this case cultures were taken from the throat by the Health Department and diphtheria bacilli were found. The defence of the "healer" is that death resulted not from diphtheria, but malaria. He was found guilty and fined $250 and $28.40 costs.

Report Regarding Smallpox.—Health Commissioner Wende has submitted a detailed report to the Board of Aldermen concerning smallpox in Buffalo. He reported that during the past four months there were 13,226 cases and 431 deaths, in 36 states of the union. Since April last 13 cases were observed in Buffalo. Eight have been cured and five are still under treatment in the hospital. Some of the difficulties in the work of detecting cases and securing public protection are illustrated in the case of Vincent Suracci who while ill of the disease at its height continued to dwell concealed in his home in a crowded tenement house and who, fearing detection and removal to the hospital, absconded to the home of friends near by, to which he was traced with difficulty, and where he was apprehended. This case necessitated the vaccination of the inhabitants of the entire street and its contained tenement houses, which was only feasible by doing the greater part of the work at night with police assistance to secure the whole number.

New York City.

The Hospital Saturday and Sunday Association of New York reported at its November meeting that two years ago the total receipts aggregated $70,000 and last year that it was $74,000, while for the pending collection it was expected that the total would reach $80,000.

Decision on Bequests.—A decision which is of considerable interest to hospitals and various charitable institutions, has just been handed down by the Court of Appeals. It is to the effect that all charitable institutions must pay the state inheritance tax on bequests. The decision was with reference to bequests made by the late Collis P. Huntington to the Roosevelt Hospital, the Hospital for Ruptured and Crippled, and a number of well-known charitable institutions.

Ambulance Accident.—A Sixth Avenue electric car crashed at full speed into an ambulance of St. Vincent's Hospital. Striking it squarely in the middle, the ambulance was completely wrecked, and the driver and Dr. J. W. Cabannis, were

thrown out and severely injured. Because of the frequency of these collisions, and because no attention has been paid to complaints, the hospital authorities declare their intention of bringing suit against the railroad company.

A convalescent hospital is to be established by St. John's Guild at New Dorp, Staten Island, Richmond Borough, for the care of women and children. The announcement of intention was made at the annual meeting of the Guild, November 12, when the annual report was read. During the past summer 61,114 mothers and children were carried out on the salt-water for a day of rest and treatment. Nearly 34 per cent. of that number were bathed in the salt-water bathrooms, and during the last year 2630 cases were admitted in the seaside hospitals, an increase of 24 per cent. over the largest previous year. The treasurer reported as received $119,374.78, an increase of $37,790.64 over 1900; the disbursements were $88,717.97, of which $25,680 were expended for buildings, improvements and repairs, leaving a balance on September 30 of $31,839.33. The Guild's membership is quoted at 1000, which shows an increase of 23.5 per cent. over the preceding year.

OHIO.

St. Clair Street Hospital, Cleveland, is to have a $10,000 addition in the early part of next year.

Fire at Starling.—A fire occurred at Starling Medical College, Columbus, November 9, which started in an incubator in the laboratory and did damage amounting to more than $1000.

Hospital Site Donated.—H. H. Hall, Ashtabula, has offered the city a half acre of land to be used for hospital purposes. The only provision is that a $5000 hospital building shall be erected thereon.

Communicable Diseases.—Springfield has an epidemic of scarlet fever and measles.——Diphtheria and scarlet fever are increasing in Columbus, and causing much anxiety.——At Zanesville it has been decided that there is no need of reclosing the schools of the city; that there is no diphtheria epidemic, and that the usual means at the command of the board of health is sufficient for the occasion.

Prevention of Smallpox.—The current issue of the Ohio Sanitary Bulletin states that from April, 1898, to Oct. 1, 1901, more than 9000 cases of smallpox had been reported in the state, with 124 deaths, and that practically every county had been invaded by the disease. It also gives plain and concise information for local boards of health regarding the detection of smallpox; isolation hospitals; quarantine, its duration and the support and aid of persons isolated; vaccination; disinfection, and burial of the dead.

Cincinnati.

Dr. Samuel E. Newman has returned from his six-month study tour of Europe, November 8.

Low Death-Rate.—According to the report of the Health Department just presented to the Board of Public Service, the annual death rate for the year covered was 16.60 per 1000 of population, the lowest mortality rate shown by the records for twenty years past. The total number of deaths was 5,412; births, 5,548.

Interne Changes.—The terms of Drs. Walter Stix, William Prichard, W. J. Taylor and Shaler Berry, as internes to the Cincinnati Hospital, expired on November 10, after a service of sixteen months. Dr. Stix will leave for Europe to further his education; Dr. Prichard has been appointed assistant surgeon to the State Insane Asylum at Columbus; Dr. Berry will locate at Newport, Ky.; Dr. Taylor will become associated with his father in Cincinnati.

Personal.—It has been officially announced that Dr. Frederick D. Barker, Dayton, has been appointed chief surgeon of the Cincinnati, Hamilton and Dayton Railway Company, filling the vacancy occasioned by the death of Dr. Ramsey. Dr. Barker's headquarters will be at Dayton, Ohio, the appointment taking effect November 12.——Dr. Charles V. Herdliska, now Secretary of Legation at Vienna, has been appointed United States Consul to Kingston, Jamaica.

PENNSYLVANIA.

Dr. George S. McLeod, Jr., Bryn Mawr, has abandoned his practice and home and has gone to Whitehall to take care of the nine smallpox patients in that suburb.

Smallpox Spreads.—During the past week, 72 new cases of smallpox were reported to the Philadelphia Board of Health, with 8 deaths. At present, 219 cases of the disease are under treatment in the Municipal Hospital and at their homes.

School Board Changes.—Drs. George I. McLeod and Samuel S. Stryker, who had been for nearly thirty years members of the Philadelphia School Board, resigned recently. Dr. Victor C. Roberts has been elected a member to fill the vacancy.

Teachers Must Be Vaccinated.—In Common Pleas Court No. 4, Philadelphia, November 14, President Judge Arnold filed an opinion, refusing to grant an injunction in the proceedings recently begun by Mary Helen Lyndall against the Board of Education to have the defendants restrained from interfering with her continuance as a teacher in the Girls' High School. The court ruled as follows: "As school directors may, in the exercise of a sound discretion, exclude from the public schools pupils who have not been vaccinated, as was decided by the Supreme court, so may they exclude teachers and other employes for the same reason. The protection which vaccination is believed to afford must be reciprocal; teachers and pupils are alike entitled to protection against contagious disease. Whether vaccination is a preventive of smallpox, this court has no power to investigate and decide. The Legislature has authorized, and the Supreme court has legalized, regulations requiring vaccination, and therefore a court in the first instance is prohibited from inquiring into the efficacy of vaccination as a preventive of smallpox. The opinion of the plaintiff that vaccination is not a preventive, and that it is dangerous to her health, is not a sufficient reason to exempt her from obedience to the order of the Board of Public Education requiring vaccination; hence the offer of the plaintiff to show that she considered it dangerous to her health was irrelevant and immaterial and was properly rejected." The court further held that the Board had the power to make and enforce such a rule as was made, that Miss Lyndall had refused to comply with the regulation and was therefore subject to suspension or dismissal.

TEXAS.

Dr. George R. Tabor, Texas' new health officer, has quarantined against Liverpool on account of bubonic plague, and all vessels will be subject to detention coming from infected ports.

Restriction of Sale of Poisons.—The San Antonio City Council, on November 4, passed an ordinance prohibiting the sale of morphin, cocain or other poisonous drugs, except upon prescription of a reputable physician.

Personal.—Dr. Charles F. Norton, quarantine officer at El Paso, has resigned to accept the position of clerk and assistant health officer of the state.——Dr. Clay Nichols, Yoakum, has moved to Gonzales.——Dr. Watson G. Terry, Denison, has located in California.

Compulsory Vaccination.—The El Paso ordinance requiring compulsory vaccination became effective November 11, for the winter season. Vaccination officers will scour the Mexican quarters of the city to vaccinate inhabitants, and all pupils of the public schools will be required to present certificates from their family physicians to show that they have been vaccinated. The children of the poor will be vaccinated by the city.

WEST VIRGINIA.

Applicants for Licenses.—At the meeting of the State Board of Medical Examiners, held in Huntington, November 11-13, forty-two applicants registered for examination.

Hospital Closed.—The St. Luke's Hospital, Parkersburg, which was principally maintained by the Ohio River Railroad Company, was closed November 15, as the Baltimore and Ohio would not maintain it.

Personal.—Dr. James W. McDonald, Benwood, has been appointed superintendent of Miners' Hospital, No. 3, Fairmount, with Dr. William C. Jamison as assistant.——Dr. Thomas F. Downing, New Martinsville, has received an appointment as superintendent of Miners' Hospital, No. 2, McKendree, vice Dr. Albert G. Stalnaker, resigned.

Communicable Diseases.—Considerable anxiety prevails in Martin's Ferry by reason of the spread of diphtheria.——An epidemic of diphtheria is raging in Keyser, where 75 cases have been reported.——At Hedgesville the prevalence of diphtheria has caused the closure of the public schools.——Typhoid fever is causing anxiety at Jim's Branch, near Bowen.

WISCONSIN.

Diphtheria is epidemic in Peshtigo and in Daggett, and scarlet fever in Waterloo, where the public schools have been closed.

Dr. E. J. Addison, Marinette, has started for New York. He expects to study there and in Edinburgh, going then to Australia, whence he will return to practice in Marinette.

Antigo Hospital.—Drs. Ignatius D. Steffen and Fred V. Watson, Antigo, have remodeled the old hospital building, increased its accommodations, added a modern operating room, and equipped it.

Waupaca County Insane Asylum.—The plans for the county insane hospital at Weyauwega have been approved, and the contracts let. The building will cost about $80,000 and will accommodate 125 patients.

Logging Camps Closed.—At the instigation of government officials, Senator William O'Neil, Washburn, closed all of the logging camps on the Bad River reservation, November 13. It is presumed that fear of a smallpox outbreak is the cause.

GENERAL.

Plague in San Francisco.—The death of a Chinaman, supposedly from the bubonic plague, occurred in San Francisco, on November 4, according to the lay press.

Dr. John F. Anderson, assistant-surgeon of the Marine-Hospital Service, has sailed on the *Lucania* for Liverpool, where he will investigate the recent plague outbreak.

Dr. William Lee Howard, Baltimore, will shortly bring out, it is said, a study in dipsomania entitled "The Perverts." It is dedicated to Edgar Allan Poe, and is in part a justification of that writer's life.

An Impostor.—It is reported that a certain "Dr. Decker," proclaiming himself a German, has been borrowing money from physicians in Fort Dodge, Iowa, and possibly elsewhere, by working on their sympathies with a tale of woe and of a rich uncle.

CANADA.

Smallpox.—Two deaths occurred from smallpox in St. John, N. B., November 15. Five new cases were reported, which now makes 51 cases in all, with 7 deaths.

Personal.—Dr. J. D. Lafferty, Calgary, N. W. T., has been appointed Registrar of the College of Physicians and Surgeons for the North West Territories in place of Dr. H. U. Bain, deceased.

Dr. George T. Orton, Winnipeg, died on the morning of the 14th inst. He was born at Guelph in 1837, and represented Centre Wellington, Ontario, in the Dominion House of Commons from 1874 until 1890.

Osteopaths Organizing for Defense.—As a result of the recent trial in the Toronto Police Court, and the action of the Ontario Medical Council, the osteopaths contemplate organizing into a body, to be known as the "Ontario Osteopathic Council."

Alumni of the Toronto General Hospital have elected the following officers: Hon. president, Dr. J. T. Fotheringham; Hon. vice-president, Dr. Goldie; president, Dr. F. A. Cleland; vice-president, Dr. A. Chisholm; secretary-treasurer, Dr. J. H. Brent; committee, Drs. O'Brien and Currie.

McGill Medical Buildings.—McGill has just completed unexcelled laboratories for the study of bacteriology, physiology and pathology. They are fitted out with all the most elaborate and scientific instruments; each student will be supplied with a complete set of necessary apparatus. The Medical Faculty will hold the annual banquet on December 6.

Wholesale Poisoning in Montreal.—At the regular meeting of the Hygienic Committee of Montreal the City Analyst presented a rather startling report. An entire family in the city had been poisoned through eating canned apples; an examination of the solder revealed that there was over 70 per cent. lead therein. An analysis of the apples and juice showed them to contain dissolved tin.

Compulsory Vaccination.—The smallpox epidemic throughout the province of Quebec has reached such a critical stage that the Provincial Board of Health now insists upon all municipalities within four days enforcing the regulations with regard to compulsory vaccination, particularly applying to manufactories and educational institutions, and a certificate must be forthcoming that the pupil or workman has been successfully vaccinated within the last seven years.

The Lumbermen and Vaccination.—An order has been issued by the Quebec Board of Health to the proprietors of shanties throughout the province of Quebec, calling upon them to have all their men vaccinated before undertaking the winter's work in the woods. The latest outbreak in the province is at Sorel, where a number of persons are affected. Dr. Beaudry, chief inspector of the board, is investigating at that place and making arrangements to have the regulations of the board carried out.

New Hospital Wing at Hamilton.—The Billings Memorial Wing, a recent addition to the City Hospital, was formally opened on the afternoon of November 12. The donor of the new wing is Mr. John Billings, of that city, and commemorates the memory of his late wife. A new nurses' home is also in contemplation of being erected, the ground for which has already been purchased. The graduating exercises of the Training School were held the same afternoon, when 8 nurses received their diplomas.

Consumption of Liquor and Tobacco in Canada.—The excise returns for the official year ending June 30, 1901, gives an idea of the quantity of drink and smoke in Canada. Beer is the favorite beverage, its consumption per head of the population being 4.737 gallons, as against .765 gallons of spirits and .1 gallon of wine. This is an increase over the preceding year, which was as follows: Beer, 4.364 gallons; spirits, .701 gallons; wines, .085 gallons. The consumption per head of tobacco was 2.404 pounds, as against 2.3 pounds for the previous year.

Grand Jury Presentment on Eddyism.—In the presentment of the grand jury which served at the recent criminal assizes at Toronto, the following reference is made to the case of eddyism before that court: "The weakest point in this case appeared to be that the party most directly and morally responsible for the imposture—if it be such—is the demonstrator, and, as the law stands he can not be held liable, therefore a change seems desirable, which would prevent anyone not a legally qualified physician acting as a substitute for such aid; the prescribing of medicine or other physical treatment should not be necessary to render the demonstrator liable to action." Justice Ferguson complimented the jury on its presentment.

A New Maternity Hospital for Montreal.—At the annual meeting of the Board of Directresses of the Montreal Maternity Hospital held last week, a new site for the purposes of a building, comprising 16,000 square feet, was purchased at a cost of $10,000. The new building will be constructed on the most approved plan, will have accommodation for 45 beds, and will cost between $30,000 and $40,000, exclusive of equipment. The physician's report stated that there remained in the institution at the end of last hospital year, 7 patients, and that during the year there were 229 confinements; one patient had been transferred to the General Hospital, and 9 remained in the institution at the close of the past year. There had been 27 applications at the Training School, 15 being accepted. Eleven nurses were graduated during the year.

FOREIGN.

Smallpox in Vienna.—A dispatch to the press, on November 19, states that Vienna is experiencing a smallpox epidemic: on the 18th, 35 new cases were reported.

A Vegetarian Orphan-Asylum.—The municipal authorities of Breslau have taken the necessary steps to accept the Baron legacy of half a million marks for the foundation of an asylum for children, to be exclusively vegetarian. The legacy was originally bequeathed to the city of Berlin, but was declined.

Passports Not Issued to Consumptives.—The *Allg. Med. Cent. Ztg.* of October 16, states that Russia, Germany and Roumania have entered into a mutual agreement that in future no passports shall be issued to persons with pulmonary affections.

Campaign Against Malaria in Italy.—The Red Cross has stations ready for the campaign against malaria on the Roman Campagna. Two stations are to be equipped for comparative research. One is to be amply protected with screens, and the inmates will be treated with quinin. The inmates of the other station will depend exclusively on Koch's method of warding off malaria by prophylaxis, with quinin for their protection.

Deaths Abroad.—The death is reported of Dr. J. C. Haentzche, physician to the German embassy in Persia. His mastery of Oriental languages was so perfect that he was summoned every year to Berlin to conduct the examinations in the Oriental Seminary.——The historian and editor of Schmidt's Year-Books, Dr. J. A. Winter, has also recently died at Leipsic in his 86th year. He has been librarian at the university since 1859 until quite recently.——A prominent surgeon of Stettin, Dr. C. Schuchardt, has recently succumbed to blood poisoning.——Munich has lost Dr. G. Naster, one of the pioneers in the battle of the clubs.

Infected Antitoxin.—Criminal proceedings have been instituted against Belfanti and Leoni, the director and assistant at the Milan institute which made the diphtheria antitoxin that caused the death from tetanus of a number of children this year. They are accused of criminal negligence in the preparation of the serum. It was established that at previous times the antitoxin had induced anthrax and glanders and that it was not of standard strength. The accused attribute the contamination to dust from a neighboring structure which was being torn down at the time, but the court would not accept this explanation. The case has been postponed for bacteriological tests.

LONDON LETTER.

Plague in Liverpool.

Great Britain has been once more visited by plague—in two of its great seaports, Liverpool and Glasgow. It will be remembered that in the latter town a very severe outbreak occurred last year. At the end of September or beginning of October 5 or 6 cases of illness occurred in Liverpool which were set down as influenza though plague was suspected. The patients were isolated, and two of them—little boys—died. It has now been definitely ascertained that the disease was bubonic plague. On October 23 two brothers, aged 12 and 7 respectively, were admitted to hospital as suffering from typhus fever. On October 28 suspicions arose as to the nature of the illness, which led to investigation of the locality whence the patients came. A woman aged 29 was found ill in a house in the rear of that where the boys lived. It was also ascertained that her mother and sister had died on September 28 and October 3, after brief illnesses. One of them was alleged to have complained of tender armpits. The deaths were certified as influenza. On October 18 a woman who had associated with this family died, and her death was certified as due to apoplexy. On October 26 two children, playmates of the family, were removed to hospital suffering from plague. The patients are well-to-do persons, and there is no connection of the cases with filth or squalor. From time to time during the past two years, cases of plague have arrived at Liverpool, but ample precautions have been taken and averted an outbreak. Three patients are now in hospital and are progressing favorably. No fresh cases have occurred since October 26 (ten days ago), so that there seems reason to think that the disease has been restricted. One theory as to the origin is that a policeman who lodged in the house where the first case occurred and had charge of a mortuary and handled the bodies of persons found drowned in the Mersey was the source. He is now isolated in an hospital.

Plague in Glasgow.

Several cases of illness occurred recently in a prominent hotel in Glasgow. The patients were servants employed on the basement floor. The symptoms were those of bubonic plague. Three persons—two men and a woman—were removed to hospital. Bacteriologic examination has proved that the disease is bubonic plague. One of the patients has died, another is seriously ill, and the third is progressing favorably. On October 30 another female servant was removed from the hotel ill. The disease is believed to have been due to the large number of rats in the hotel, which have been driven there by the demolition of a number of houses. A fourth case has occurred in a barmaid who slept for a night at the hotel. Twelve members of the staff of the hotel have been isolated and will be kept so for fourteen days. An active campaign is being organized against the rats. In two hours no fewer than 200 were killed in the hotel. The hotel is one of the largest in the country and contains 400 bedrooms. Two hundred people were on the premises on the night of the outbreak. The staff of servants numbers 300. The hotel has been emptied of guests and all the servants inoculated with anti-plague serum and placed under medical supervision.

Smallpox Increasing in London.

The number of cases of smallpox in London is still increasing. According to the last report there are 283 cases in hospital. A temporary smallpox hospital is being erected at Dartford at a cost of $250,000, and a permanent one at Hither Green at a cost of $1,500,000. As many as 29 fresh cases have been notified in one day. At present all the patients are received on hospital ships moored in the Thames. The authorities evidently expect that the relatively great immunity from the disease which London has long enjoyed will not be continued in the future. It is expected that with the advent of the cold weather the outbreak will increase. The mortality is high and indicates a virulent type, which must be connected with the neglect of vaccination previously referred to in THE JOURNAL. Thirteen persons have died and 87 have been discharged. The re-vaccination of adults is going on on a large scale. In the streets and public places persons are to be seen with a band of tape around the arm. The significance of this is now well known. It is a "danger signal" to prevent grasping or rubbing against the vaccinated arm. By command of the king all the servants in Marlborough House have been vaccinated.

Death of a Great English Chemist.

Sir Edward Frankland, who recently died while on a vacation in Norway, was the subject of a memorial lecture at the Chemical Society by Professor Armstrong, one of his pupils. His fame rested chiefly on his discovery of the law of valency or atomicity, and he probably ranks next to Davy in the roll of English chemists. He was born in 1825, and at the age of 15 was apprenticed to a druggist. In 1845 he studied at the Museum of Practical Geology in London under Sir Lyon Playfair. Two years later he was elected a Fellow of the Chemical Society. In 1853 he was elected F.R.S., received the royal medal of the Royal Society and was appointed lecturer on chemistry at St. Bartholomew's Hospital. A very important part of his life work was his study of water analysis and purification. In 1865 he was asked to continue Hoffman's monthly analyses of the metropolitan drinking water, which he continued to do until his death. He also investigated the pollution of rivers, the purification of sewage and domestic water supply. He was an intensely reticent and self-contained man, and never played for place or power.

Sir Henry Thompson on Diet.

Sir Henry Thompson, who until he relinquished active practice, was the foremost genito-urinary surgeon in Great Britain and worked contemporaneously with Bigelow, is now hale and hearty at the age of 82. He is not only a great authority on his own branch of surgery but also on dietetics. He also interests himself in the subject of cremation and is president of the English Cremation Society, whose objects he has done much to further with his pen. He has just published a remarkable book on "Diet in Relation to Health," in which his personal experience is a striking object lesson. Thirty years ago, at the age of 52, he gave up alcohol. For the sake of experiment five or six years back he tried the effect of a claret glass of good wine at dinner every day for two months. Then the sick headaches and pains in the joints from which he had suffered in early life came back until he abstained again. Moreover, "after abandoning alcohol, the joints gradually lost their stiffness and ultimately became as supple and mobile as they were in youth and continue absolutely so to this day." He adds: "It may be fairly said that one example does not prove a case. But it is not a single example, and really designates a very large class of active men possessing a more or less similar temperament of which a type is here described." Half our bodily ills are due, he believes, to improper feeding. The necessity for diminishing the amount of nourishment taken as one grows older is not appreciated "The extra glass of cordial, the superlatively strong extract of meat" are mistakes. Sir Henry draws an alarming picture of the head of the family sinking to decay because his affectionate spouse plies him with dainties he can not digest—the egg whipped up with sherry, the insidious calves' foot jelly, the inopportune cup of cocoa. She urges him to try patent foods which are so "nutritious" that his stomach can not stand them, and she imagines that even his drinks must have nutriment, forgetting that the primary object of drink is to satisfy thirst, and that to take milk, for example, with meat is one of the greatest dietic blunders that can be perpetrated. Even the dentist shares in his condemnation. He gives the patient a set of masticators as efficacious as the originals, but he does not warn the patient that the body needs less food than in the heyday of life. Though not a vegetarian, Sir Henry maintains that three-fourths of our food should be vegetable. This ensures a lighter and more active brain. The light feeder, after his meal, has fresher wit and more cheerful temper. He does not snore in the armchair. Dyspepsia is unknown to him.

Nitric Acid in Noma.—During a severe epidemic of noma following measles G. Cavazzani cured 39 out of 60 cases, by cauterizing the necrosed tissues with nitric acid on a pad of cotton. This proportion of 65 per cent. of recoveries compares favorable with the 27 per cent. recoveries obtained by other methods of treatment during an epidemic in the preceding year. —*Gazzetta degli Ospedali*, October 13.

Correspondence.

"Sanitary Sleeping-car Accommodations."

BURLINGTON, Iowa, Nov. 14. 1901.

To the Editor:—The abuse of the sleeping-car toilet room as complained of by your correspondent and made the subject of editorial comment in THE JOURNAL of November 9, should be a topic of interest to every one who has the health of the traveling public really at heart.

I rode in a sleeping car once, and while I was much more comfortable than some folks might think possible, I still feel that I might have had more for my money. Two dollars a night for a double berth three-quarters wide is enough. But when one has also to contribute an additional 25 cents towards the porter's salary, get an indifferent brush and shine, and see the wash basins used as described, there is room for one to feel that he has been "buncoed."

For that extra quarter one has a right to imagine that the porter should either furnish a special wash basin for each passenger, put the small supply usually on hand through a steam sterilizer, or make an inspection of the passengers individually, to the end that the passengers having lunch-counter remains in their mouths, sooty noses, hands begrimed with infectious dirt, and un-Chesterfieldian manners generally, may be debarred from the use of the basins altogether. Or it might answer the purpose if the basins were numbered and labeled thus: No. 1, wash hands only; No. 2, for faces only; No. 3, for mouths and noses, etc.

I am told that in England they manage these things better. There, every one is expected to bring his tub with him. Years ago I heard an old lady say to her son, who was starting out on his first long journey: "My boy you should be content when you get a clean bite, a clean bed, plenty of good water, soap and towels. People who have these things away from home and complain, may be set down as not having many comforts at home." But I think the old lady had never traveled in a sleeping car.

In conclusion I want to advise every one to do as I did that time I was in the sleeping car. Before using the basin I washed it out carefully and dried it with a clean towel (as I always do when I have strange basins, and frequently those at home). Then I proceeded to forget every unpleasant thing I had seen, and when I got home I found that I had not caught anything. Truly yours, H. B. YOUNG, M.D.

Miscellany.

A new x-ray effect has been developed in the laboratory of the Bellevue Hospital Medical College, New York, which, as described in the current *Electrical Review*, displaces the silhouette with the stereopticon. By using two sources of *x*-rays in the same tube of the apparatus designed for the purpose, the picture stands out distinctly with the intervening spaces of the objects viewed. The relations of the broken bones, etc., to their surroundings as thus indicated to the eye, it is expected, will be of great value as surgical and pathological guides to diagnosis.

Trailing Dresses at Health Resorts.—The authorities at Ems placarded the walls at the beginning of the season with an appeal: "In the interests of the public seeking health at this resort, every effort is made to prevent dust and to prevent its diffusion in the air during the dry and hot season, as is urgently required by consideration for affections of the respiratory organs. The streets and grounds are kept sprinkled to keep down the dust as much as possible, and the feminine portion of the public would essentially contribute to this end if they would refrain from trailing their skirts at this health resort. This is especially desirable during the morning promenade to and from the springs." The *Deutsche Med. Wochenschrift* states that the appeal has had no effect, as "might have been anticipated from the character of the sex which is certainly the weaker sex as far, at least, as the mandates of fashion are concerned." It adds that as the matter is one that affects the general public health, the central health authorities for the empire should take steps to regulate it.

The International Sanitary Congress.—At the recent Pan-American Medical Congress at Havana, the organization of an international sanitary congress was recognized as a necessity. It has now been completely organized and will meet at Havana, Feb. 15, 1902. It is for the purpose of conferring on sanitary matters affecting the various Pan-American countries collectively and individually. Each country is entitled to three delegates, a physician, an engineer and a merchant. The duties, rights and penalties of each country in respect to sanitary matters will be discussed, and the means to aid those nations without resources for such measures for the public health. The Congress will also discuss prophylactic measures in general, and as applied to each particular port. The greatest publicity is desired and membership is open to all men of science, manufacturers and merchants who apply to the committee of organization. Dr. Thomas V. Coronado, of Havana, is secretary, and Dr. Juan Santos Fernandez is president. English, Spanish, Portuguese and French are to be the official languages of the Congress. Further particulars will be furnished on application to the secretary.

Loeffler's Suggestion of the Treatment of Carcinoma by Induced Malaria.—It is an old-established fact that malaria has a favorable influence on the course of certain pre-existing diseases. Hippocrates asserted that persons affected with quartan fever did not become epileptic, and that quartan fever occurring in an epileptic cured his epilepsy. A Hungarian professor of anatomy published in 1775 the history of a case of mammary cancer cured in the course of a few weeks by an intercurrent double tertian fever. Loeffler thinks that these and similar facts justify the attempt to cure carcinoma by artificially inducing malaria, which is a disease over which we have effective control. He suggests that possibly the increase in cancer in temperate countries may be due to the extinction of malaria, and calls attention to the extreme rarity of cancer in the tropical, that is, the malarial-infested countries. He urges physicians in the tropics to collect data in this line, and cites Pagel, who states that he can not remember a single case of cancer in ten years of practice in northern Borneo. Loeffler concludes his communication to the *Deutsche Med. Wochenschrift*, just received, with the assertion that physicians would be justified in experimenting on an extensive scale to cure carcinoma by the inoculation of malaria.

Women in Medicine.—Two important historical works have recently been published in Paris on this subject, one by Melanie Lipinska, and the other by Marcel Baudouin. The latter was undertaken in honor of the semi-centennial of the admission of Elizabeth Blackwell to the medical profession, Jan. 23, 1849. Woman's progress during the last decade has been remarkable. In Russia there has long been complete equality between men and women physicians, and women have recently won their cause in Hungary, Austria and Germany, and the prejudices against the admission of women to the medical profession are rapidly subsiding even in France. Spain still refuses to recognize medical women, although two and three centuries ago several Spanish women acquired some fame by their practice of medicine. Women physicians are now recognized in Belgium since 1890, in Italy since 1878, in Portugal since 1886, in Mexico since 1887, in Sweden since 1870, in Switzerland, Roumania, Bulgaria, in this country and Australia. Baudouin relates the history of Henrietta Faber, who practiced medicine in Havana for years, disguised as a man. She married in 1820 and was at once prosecuted and condemned to ten years of imprisonment. Medical women were numerous in ancient Greece and Rome, and in Italy during the Middle Ages.

The Scientific Investigation of Consumption Cures.—There is a general feeling among the public that methods of treatment of consumption which are not brought forward

through the orthodox channels are systematically boycotted by the medical profession. The argument is one, moreover, which is put forward by irregular practitioners who lay claim to having discovered a "cure" for this too prevalent disease. It will be news to many of our readers that provision at the Brompton Hospital for Consumption for the investigation of remedies for consumption was made nearly half a century ago, and is still available. According to a letter from Dr. J. E. Pollock, which was published in a recent number of *The Times*, the medical officers of that institution are authorized by the committee to avail themselves of any novel method of treatment which offers a reasonable prospect of usefulness. The only condition is that the nature and preparation of the proposed remedy shall be made known to them in writing. The authorities even go the length of admitting the person proposing such remedy to the hospital to observe its effects. A very large number of remedies and methods of treatment have been tested —and found wanting—in virtue of this permission; but it is a significant fact that no secret or other remedy has ever been submitted by outsiders on these conditions, not even the at present notorious Lachnanthes. Of course everything would turn upon what the medical officers considered "a reasonable prospect," and this, it would seem, has not been put to the test for the simple reason that quacks and men of the Alabone type prefer to compile their own statistics, and carefully steer clear of any scientific control.—*Medical Press and Circular.*

Old-Fashioned Fees.—Dr. John Radcliffe (1650-1714), a Yorkshire man by birth who removed in 1684 from Oxford to London, has come down to the present generation with the credit of an exceptional recipient of large fees. He has been described as a brusque, witty, somewhat dictatorial physician who caught the fancy of royalty almost from the start. His strictures upon the feeble pharmacy of his competitors have been mentioned as contributing to his success as a treasurer of honorariums. For attendance on William III, during the first eleven years of his reign, he had on the average more than 600 guineas per annum and was once "ordered 500 guineas out of the privy purse for the cures of M. Bentinck and M. Zulestein." On another occasion, having been sent to Namur to cure Lord Albemarle, after a week's residence in the camp abroad, his majesty gave him a treasury order for £1200, and the patient with a rare gratefulness presented him with 400 guineas and a diamond ring of "envious glitter." Dr. Gibbons, Radcliffe's neighbor, profited by his overflow to the extent of more than £1,000 per annum and a certain apothecary by recommended patronage died worth £50,000. Allowance, however, must be made for high expenses and the depreciation of money values since Dr. Thomas Young (1773-1829) was wont to say that no one should attempt to establish in London who had not a private fortune of £500 or £600 a year. As a whole, the present is a practical age abounding in competitors on the one hand and capricious patients on the other. In this fair land there are many rumors of fortunes made during the hours of sleep, but somehow the statistics are not all on hand, or else popular faith may be awry. At all events, many like John Hunter have been peevish over a guinea when won at the expense of an interrupted investigation, and let it be remembered that physicians are spasmodic accountants.

Annual Convention of the Nation's Doctors.—One of the most important conventions to be held in Saratoga in 1902 is that of the American Medical Association, which is dated for June 10 to 14, inclusive. Last week Dr. John A. Wyeth, of New York, president of the American and State Medical associations, and Dr. George H. Simmons, secretary of the American Association, were in Saratoga to meet the local physicians and discuss plans for the convention. The officers came up from New York, and were accompanied by Dr. George F. Comstock, of Saratoga, chairman of the hotel committee of arrangements, who had been in New York in attendance upon the meeting of the State Medical Association. The meeting of the Saratoga physicians was held in the parlors of the Worden hotel, those present being Drs. Comstock, Hewitt, Church, Resseguie, Humphrey, Fish, Van Arnam, Varney, Moriarta, Ledlie, Downs, Thompson, Deuell, and J. R. Swanick. President Wyeth addressed the meeting and told the plans the State and American associations had for making the convention a success, and said that it would be his aim to make the meeting, scientifically, the most important of any ever held. Secretary Simmons followed and spoke enthusiastically of Saratoga as a convention center. He then outlined some of the work necessary for the local committee to do during the ensuing months in preparation for the convention. Following the meeting, those present were entertained at dinner at the Worden by Dr. Comstock. Drs. Wyeth and Simmons returned to New York on the afternoon train. The American Medical Association will bring together about 5000 delegates, together with their wives and other members of their families. The general meeting will be held in convention hall, while at the same time there will be sessions of specialists in the smaller halls. A feature of the convention, and one from which no little revenue is derived, is the exhibit of the supply men. The exhibit will be in the bottling room of the Hathorn spring, which even at this early date has been secured for that purpose.—Glens Falls (N. Y.) *Times*, Oct. 30.

Married.

EUGENE J. GAY, M.D., to Miss Blanche M. Slade, both of Algona, Iowa, October 30.

CHARLES M. FREEMAN, M.D., to Miss Mary E. Wilkins, at Metucken, N. J., November 15.

ARNOLD B. MCCARTY, M.D., to Miss Lillie Bell Miller, both of Owensboro, Ky., November 6.

ARTHUR GALLMAR, M.D., Barabeo, Wis., to Miss Blanche Guertin, St. Anne, Ill., November 9.

EDWARD DANA MITCHELL, M.D., to Miss Annie Bogardus Tracy, both of Memphis, Tenn., November 6.

HENRY F. AIRTH, M.D., to Miss Bessie Porter, both of Live Oak, Fla., at Jacksonville, Fla., November 7.

HUBERT ASHBY ROYSTER, M.D., Raleigh, N. C., to Miss Louisa Page, at Princess Anne, Md., November 6.

JAMES CARPENTER COBEY, M.D., Frostburg, Md., to Miss Elizabeth Kownsler Earle, Milldale, Va., November 14.

JAMES WALTER RENDLEMAN, M.D., East St. Louis, Ill., to Miss Marie Elizabeth Park, St. Louis, Mo., November 5.

HAMLINE NICKLESON DEEM, M.D., Tyner, W. Va., to Miss Edna Ellen Ramsey, Blennerhassett Island, W. Va., at Marietta, Ohio, November 9.

Deaths and Obituaries.

Albert Leary Gihon, M.D., Philadelphia College of Medicine and Surgery, 1853, Commodore U. S. Navy (retired), died November 17, at Roosevelt Hospital, New York City, after an illness of three days, from apoplexy, aged 68. Dr. Gihon was a native of Philadelphia, and there received his education. The year after his graduation he was appointed professor of chemistry and toxicology in the Philadelphia College of Medicine and Surgery. On May 1, 1855, he entered the Navy as assistant surgeon. His first foreign service was on the sloop of war *Levant*, on the East India station. He participated in the engagements which resulted in the capture of the Barrier Forts on Pearl River, near Canton, China. He also served on the *Dolphin* during the Paraguay expedition in 1858 and 1859, and on the *Preble* on the Coast of Central America and Panama. He received his grade as passed assistant surgeon May 1, 1860, and was on duty at the U. S. Naval Hospital, Brooklyn, in 1861. He was promoted to surgeon on August 1, 1861, and from 1862 to 1865 was on special duty on the *St. Louis* on the European Station, and cruising along the Atlantic Islands after Confederate privateers. In 1864 he participated in the blockade of the coast of South Carolina and from 1865 to 1868 was senior medical officer at Portsmouth, N. H., Navy Yard; from 1868 to 1870 he was attached to the store-ship *Idaho*, which was stationed at Nagasaki as hospital ship of the Asiatic squadron,

and was wrecked during the memorable typhoon of Sept. 21, 1869. In 1870 he was on special duty at Brooklyn, N. Y., was then attached to the Marine Rendezvous, Philadelphia, and later was a member of the Naval Medical Board of Examiners. On Nov. 7, 1874, he was promoted to medical inspector and was on duty at the Bureau of Medicine and Surgery of the Medical Department, and later was ordered as surgeon of the fleet to the flagship *Wabash*, on the European station. He served in the expedition of 1874 at Key West, Fla., returned to the European station as surgeon of the fleet on the flagship *Franklin* in 1874-1875. From 1875 to 1880 he was head of the medical department at the U. S. Naval Academy, Annapolis, and during this tour of duty designed and superintended the construction of the medical hospital ship for the Centennial Exposition at Philadelphia in 1876, where he also exhibited his "ambulance cot," which was approved and adopted for the use of the Navy the next year. He was appointed inspector of recruits and recruiting stations in 1878, was commissioned medical director Aug. 27, 1879, and placed in charge of the Naval Hospital at Norfolk, Va., the ensuing year. From 1880 to 1883 he was a member of the Board of Inspection of the Navy; in charge of the Naval Hospital of Washington, D. C., from 1883 to 1886; at the Hospital at Mare Island, Cal., from 1886 to 1888; of the Naval Hospital, Brooklyn, N. Y., from 1888 to 1892; on special duty from November, 1892, to 1893, and was again placed in charge of the Naval Hospital in Washington from 1893 to 1895. On May 1, 1895, he attained the rank of Commodore, having then been forty years in the naval service. He was retired from active service on Sept. 28, 1895, by the constitutional limitation of age. Since 1876 Dr. Gihon has represented the medical department of the Navy in prominent medical, sanitary and climatological associations and international medical congresses, and has been honored by election to high offices. He was a member of the American Medical Association; fellow and ex-president of the American Academy of Medicine; president of the American Health Association, 1883; vice-president of the Association of Military Surgeons of the United States in 1895, and a member of numerous American and foreign medical, historical and scientific societies. His special work was naval hygiene, and in 1871 he published a work entitled "Practical Suggestions in Naval Hygiene," which was a pioneer in that department of science. He contributed numerous articles to the literature on naval hygiene, public health, sanitary reform, state medicine, higher medical education, vital statistics, medical demography and climatology, and was for six years one of the editors of the Annual of the Universal Medical Sciences. He was the originator, and for several years one of the most active promoters of the project to erect a monument in Washington to Dr. Benjamin Rush. Dr. Gihon was married in April, 1860, to Miss Clara Montfort Campfield, Savannah, Ga., who survives him. His two sons have attained high rank among the younger American artists in Paris. He was made a Knight of the Military Order of Christ by the King of Portugal, and also received the thanks of the British and French governments for distinguished service rendered.

DR. ALBERT L. GIHON.

William Fisher Norris, M.D., University of Pennsylvania, 1861, died at his home in Philadelphia, November 18, from pneumonia, aged 63. Dr. Norris was a native of Philadelphia, was educated at the University of Pennsylvania and took his medical degree at that institution; immediately upon graduation he was appointed resident physician in the Pennsylvania Hospital. In 1863 he entered the army as assistant surgeon, served for one year, and in 1864 was placed in charge of the Douglass Hospital, Washington. At the close of the war he resigned his commission and established himself in practice in Philadelphia, making a specialty of diseases of the eye. In 1876 he was oppointed Professor of Ophthalmology in the University of Pennsylvania. He was on the surgical staff of the Wills' Eye Hospital, Vice-president of the Philadelphia Pathological Society, Fellow of the Philadelphia College of Physicians, member of the American Medical Association and of the American Ophthalmologic Society and Fellow of the Pennsylvania Academy of the Natural Sciences. His contributions to ophthalmological literature have been frequent and important. His best known work was done as editor of the "System of the Diseases of the Eye," in which he was assisted by Dr. Charles A. Oliver. This is a collection of monographs by the most distinguished ophthalmologists in this country and abroad. It is comprised in four large quarto volumes constituting the most complete study in the English language of ophthalmology in all its branches and relations. Dr. Norris wrote for this text-book the article on "Cataract and Other Diseases of the Lens."

Barton W. Stone, M.D., died in Louisville, November 13, from pneumonia complicating rheumatism after a short illness. Dr. Stone was born in Fulton, Mo., in 1844. He was graduated at Westminster College, Fulton, and shortly afterward came to Louisville and studied medicine under Dr. J. M. Holloway, graduating at the Kentucky School of Medicine in 1867. He began practice in Louisville. He was appointed assistant physician at the Western Kentucky Asylum, Hopkinsville, in 1869, under Dr. James Rodman and remained in that position until 1889, when he was appointed superintendent by Gov. S. Buckner, and was re-appointed by Gov. John Young Brown. He resigned Jan. 31, 1896, and went abroad to study asylum methods in Europe with a view of opening a private institution for the treatment of nervous diseases. In 1896 he associated himself with Dr. S. S. Crockett in the Morningside Sanitarium near Nashville, Tenn. He afterward became the proprietor, but moved to Louisville, in June, 1899, when he opened the Beechhurst Sanitarium.

J. Marcus Rice, M.D., Castleton (Vt.) Medical College, 1853, surgeon of the Twenty-fifty Massachusetts and later medical director of the Eighteenth Army Corps, in the Civil war, for 47 years a practitioner in Worcester, a member of the Massachusetts Medical Society and at one time president of the Worcester District Medical Society, died at his home in Worcester, November 11, from valvular heart disease, aged 74.

Jarvis S. Wight, M.D., Long Island College Hospital, N. Y., 1864, aged 66 years, died at his home in Brooklyn, N. Y., November 16. During the latter part of the Civil war he was in

the medical service and all through his professional life he maintained close relations with the college named. He was a member of the leading medical societies, an author, and an inventor of certain surgical devices.

Hervey McDowell, M.D., Missouri Medical College, St. Louis, 1858, prominent as a practitioner in Harrison County, Ky., lieutenant-colonel of the Second Kentucky (Confederate) Infantry in the Civil war, a member of the American Medical Association, and president of the Board of Education of Cynthiana, died at his home in that place, November 6, aged 65.

Charles Magill Smith, M.D., University of Pennsylvania, Philadelphia, 1847, a resident of Franklin, La., for more than fifty years, surgeon in the Confederate service during the Civil war, since 1879, president of St. Mary's Parish Board of Health and Coroner, died at his home in Franklin, November 7, after a short illness, aged 75.

William Seward Millener, M.D., Queen's College, Kingston, Ont., 1864, then an assistant surgeon U. S. Army, later a practitioner in Adam's Basin and the West, and a resident of Spencerport, N. Y., for more than thirty years, died at his home in that place, aged 58.

Thomas Flavin, M.D., University of Texas, Galveston, 1892, a member of the first class graduated from that college, and then demonstrator of anatomy, recently practicing at Galveston, died at Houston, after a long illness, November 5, aged about 50.

Robert S. Hamilton, M.D., Jefferson Medical College, Philadelphia, 1857, one of the oldest physicians in Augusta County, Va., and at one time superintendent of the Western State Hospital, Staunton, died at his home in Lone Fountain, November 9.

Horace P. Woodward, M.D., University of Michigan, Ann Arbor, 1854, for many years a practicing physician of Westmoreland, Kan., and later a resident of Escondido, Cal., died at his residence in that place, October 28, aged 77.

Harvey Putnam Tolman, M.D., College of Physicians and Surgeons, N. Y., 1848, of East Onondaga, N. Y., died there, aged 78 years. He was much interested in public affairs, and in 1865 was a member of the assembly.

Helen Upjohn Kirkland, M.D., University of Michigan, Ann Arbor, 1872, who practiced medicine in Kalamazoo until 1889, died at her home in that city from Bright's disease after a long illness, November 5, aged 63.

John P. Bishop, M.D., College of Physicians and Surgeons, Baltimore, 1886, a prominent physican of Charlestown, W. Va., and a member of the American Medical Association, died at his home, November 5, aged 42.

Gustavus F. Sargent, M.D., Medical School of Maine, Brunswick, for several years a practitioner of Bangor, Maine, and Cambridge, Mass., died at his home in Dorchester, Mass., November 2, aged 79.

David A. Gibbs, M.D., New York University, 1847, who had practiced in Social Circle, Ga., for more than half a century, died at his home in that place from paralysis, November 8, aged 76.

H. Robertson Bohn, M.D., Tulane University, New Orleans, 1893, one of the leading physicians of Biloxi, Miss., died at his home in that place, November 8, after a long and painful illness, aged 31.

Howard W. Shaffer, M.D., Kentucky School of Medicine, Louisville, 1891, a practitioner of Ponca, Okla., died at his home in that place from an overdose of chloroform, November 14.

David J. Mallery, M.D., Geneva (N. Y.) Medical College, 1847, died at his home in Bristol Center, N. Y., where he had practiced medicine for 42 years, November 7, aged 78.

Arthur H. Blair, M.D., University of Nashville, Tenn., 1894, a practitioner of Dresden, Texas, died at San Antonio, November 6.

Fred J. Oelschlaegel, M.D., University of Cincinnati, 1880, died suddenly at his home in Cincinnati, November 11, aged 46.

Book Notices.

PRACTICAL SURGERY: A Work for the General Practitioner. By Nicholas Senn, M.D., Ph.D., LL.D., Professor of Surgery, Rush Medical College, Chicago. Handsome Octavo Volume of 1133 Pages, with 650 Illustrations, Many in Colors. Cloth, $6.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

This, the latest production from this well-known author's prolific pen, does not pretend to cover the whole field of surgery, but deals particularly with emergency and intestinal surgery. Much of the work has already appeared in the shape of monographs by the author during the past fifteen years. The early chapters are devoted to anesthetics, hemorrhage and wounds in general, especial attention being given to the author's experience during the late Spanish-American war. Considerable space is devoted to fractures, and the chapter on fractures of the upper end of the femur deserves particular mention as one of the best in the book. Under dislocations only those of the hip, shoulder and elbow are briefly considered. The author's elaborate "multiple" classification of peritonitis is too circumstantial, and tends to confusion. Under intestinal surgery considerable repetition is found, and much space occupied in detailing early experiments with bone-plates, rubber rings, etc., methods now of practically historical interest, concerning which the author himself says: "A more extensive experience with needle and thread has greatly modified my views." The various forms of intestinal obstruction are well described, and the chapter on Tuberculosis of the Intestine is particularly full of interesting facts. The work closes with a chapter on resection and the standard amputations. The author's well-known vigorous and impressive style is still further emphasized by the frequent use of italics. Many of the illustrations are new and original, and well selected to aid the text.

DISEASES OF THE STOMACH AND THEIR SURGICAL TREATMENT. By A. W. Mayo Robson, F.R.C.S., Member of Council and Hunterian Professor Royal College of Surgeons of England, and B. G. A. Moynihan, M.S. Lond., F.R.C.S., Assistant Surgeon Leeds General Infirmary. Cloth. Pp. 308. Price, $3.50. New York: William Wood & Co. 1901.

This work is an outgrowth of the Hunterian lectures by Mayo, at the Royal College of Surgeons in England, in 1900, and he has called in to his aid Dr. Moynihan, his associate in hospital work for many years. The book in its way fills a place in our literature that while not vacant, nevertheless has not had so many systematic monographic works upon it as some of the other subjects of regional surgery. The subject of stomach and gastric surgery has added interest to us at the present time on account of the recent discussion of the subject in President McKinley's case, and it is interesting to know that an immediate operation in such cases as that of our late President is entirely in accordance with the recommendations and teachings of the authors. While the small caliber bullets aimed at high velocity pass through the stomach and recovery is possible without operative interference, as has been shown in the recent South African experience, gunshot wounds of the abdomen we meet with in civil practice are inflicted generally by a rougher class of weapons, are more ragged and contused and do not heal spontaneously. The work is elegantly printed and illustrated, and will prove a valuable addition to the literature.

ON THE OPERATIVE SURGERY OF MALIGNANT DISEASE. By Henry T. Butlin, F.R.C.S., D.C.L., Surgeon to St. Bartholomew's Hospital. With the Co-operation of James Berry (on the thyroid), W. Bruce Clarke (on the kidney), Alban Doran (on the ovary and uterus), Percy Furnivall (on the stomach, intestine and rectum), Walter Jessop (on the eye), and H. J. Waring (on the liver and gall-bladder). Second Edition. Cloth. Pp. 426. Price, $4.50. Philadelphia: P. Blakiston's Son & Co. 1900.

Notwithstanding its merits, this work has waited twelve years for its second edition, which suggests a hitherto limited reading, though one would think that there would be surgeons enough that would find it a convenient and valuable addition to their library shelves. It is a composite work, fully one-half being by the co-operation of the above-mentioned authorities, whose names are familiar to readers of the subjects of which they treat. The work is thoroughly up to the present state of our knowledge on its subject, though there are some points, such for instance as appertain to the proctologic specialty as

developed in this country, that are not fully noticed. The authors seem to have given considerable attention to the American literature of the subject, still there are many hiatuses, which is not to be wondered at considering the great number of journals in which the surgical literature of this country is published. The book will be a serviceable one to every surgeon. What it has to say is to a large extent authoritative, the authors being recognized leaders in this line of practice.

MANUAL OF THE DISEASES OF THE EYE. For Students and General Practitioners. With 275 Original Illustrations, Including 36 Colored Figures. By Charles H. May, M.D., Chief of Clinic and Instructor in Ophthalmology, Eye Department, College of Physicians and Surgeons, Medical Department, Columbia University, New York. Second Edition. Revised. Price, $2.00. New York: William Wood & Co. 1901.

Dr. May's book, as he says in the first word of the title page, is a manual for students and general practitioners. The fact that a second edition of this work is demanded within eight months after its first appearance is presumptive evidence that it is meeting with approval. The entire field of diseases of the eye is covered, and the subjects are well subdivided. The author gives under each division a description of the anatomy of the parts; this is a most valuable addition and reminds one of the descriptions of the anatomy which Fuchs' work contains. Indeed, Dr. May's book shows many indications of influence from Fuchs' book. This is not criticism; it is praise. In this connection, the reviewer is reminded of a letter that he once saw written to a young medical student by his preceptor. The student had written to his preceptor that he was dissatisfied with his instructor in anatomy, and said that the instructor only gave what was contained in Gray. To which the doctor answered: "If your instructor gives what is in Gray, stick to him; he is all right."

SELECT METHODS IN FOOD ANALYSIS. By Henry Leffmann, A.M., M.D., Professor of Chemistry and Toxicology in the Woman's Medical College of Pennsylvania, and William Beam, A.M., M.D., Formerly Chief Chemist Baltimore & Ohio Railroad. With 53 Illustrations in the Text, 4 Full-page Plates and Many Tables. Cloth. Pp. 383. Price, $2.50. Philadelphia: P. Blakiston's Son & Co. 1901.

This work is intended as a concise summary of analytic methods for the use of practical analysts and students, and contains a large amount of matter which will be valuable reading for any physician whether he is a chemist or not. The authors do not go into the effects of adulteration to any extent, but that is hardly necessary. That is more particularly, as they consider it, the physician's business than that of the analytic chemist. The special methods for detecting adulterants, preservatives and poisonous metals are particularly shown in the text and the work is one which should be in the hands of every sanitarian and health officer, and would not be amiss as an addition to the library of every general practitioner and all those who have not at once available recourse to laboratories, etc.

PATHOLOGICAL TECHNIQUE. A Practical Manual for Workers in Pathological Histology and Bacteriology, including Directions for the Performance of Autopsies and for Clinical Diagnosis by Laboratory Methods. By Frank Burr Mallory, A.M., M.D., Assistant Professor of Pathology, Harvard University Medical School; First Assistant Visiting Pathologist to the Boston City Hospital; Pathologist to the Children's Hospital and to the Carney Hospital; and James Homer Wright, A.M., M.D., Director of the Clinico-Pathological Laboratory of the Massachusetts General Hospital; Instructor in Pathology, Harvard University Medical School. Second Edition, Revised and Enlarged. With 137 Illustrations. Philadelphia and London: W. B. Saunders & Co. 1901.

The new edition of this valuable work keeps pace with the recent advances in pathological technique, and will continue as a most useful guide to the laboratory worker, whether student, practitioner or pathologist. As a practical manual of histologic and pathologic methods in the study of pathologic material, no matter whether from the clinic or from the post-mortem room, this book fills its place admirably. Many changes and additions have been made, and new methods and new illustrations introduced.

THE PRINCIPLES OF HYGIENE: A Practical Manual for Students, Physicians, and Health Officers. By D. H. Bergey, A.M., M.D., First Assistant, Laboratory of Hygiene, University of Pennsylvania. Illustrated. Cloth. Pp. 495. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1901.

The general principles of hygiene are brought together in this work in a convenient form for the medical student and physician and the author has carried his work more particularly to matters of school, military and naval hygiene than was perhaps formerly the custom in works of this kind. The treatment of the subjects is necessarily rather concise, but the facts are clearly stated. In a general way we can say that the work is one that possesses decided advantages for the American physican and student. He gives quite a full reproduction of the quarantine laws of the United States and also of Pennsylvania quarantine legislation. A brief and useful appendix giving a conversion of the different weights and measures into the metric system, and quite a full index, add to the value of the work.

MATTHEWS' PHYSICIANS' BLUE-BOOK. A Complete Medical and Surgical Register of the State of Missouri, containing Lists of Physicians and Surgeons, with School and Year of Graduation, and List of Specialists Classified Alphabetically by Towns, Showing Population. Also the Various Hospitals, Sanitariums, Colleges and Other Institutions, State Board of Health, Societies, Journals, etc., and the Late Medical and Pharmacy Laws, 1901-1902. Cloth. Pp. 175. Price, $2.00 net. St. Louis: Lewis S. Matthews & Co. 1901.

This directory contains a list of the physicians of Missouri, arranged alphabetically according to towns, those of St. Louis being grouped together at the end of the book. The name of the college and date of graduation is given, and occasionally other facts relative to the individual. The pages are marred by heavy, black-faced type, evidently to indicate those who have subscribed for the book. Besides other information, it contains the law regarding the practice of medicine in Missouri, and the revised pharmacy laws; the medical journals, medical colleges, hospitals, sanitariums, dispensaries, charitable institutions, and medical societies of Missouri are enumerated, together with a list of counties of the state.

L'EPILESSIA. Eziologia-Pathogenesi Cura. By Dottor Paola Pini. Cloth. Pp. 277. Milano: Ulrico Hoepli. 1902.

This little work has certain decided merits. Although a compilation it is rather unique in its plan, and can hardly be well compared with any other work of its scope and kind on the subject. It is not a monographic account of the disease, as its title might imply, but rather a critical scientific résumé of the various methods of treatment and the theories on which they are based. The specialist in nervous disorders, or any one with much practice among epilepties, will find the little volume a convenient résumé of facts, judiciously stated. Its up-to-date character may be estimated by the fact that the author reproduces in full as an appendix Ceni's article on blood toxicity and serum therapy in epilepsy, read before the Italian Congress di Frenatria in October, and which has just been awarded the Craig Colony prize.

A TEXT-BOOK OF EMBRYOLOGY. By John C. Heisler, M.D., Professor of Anatomy in the Medico-Chirurgical College, Philadelphia. Second Edition, Thoroughly Revised. Illustrated. Cloth. Pp. 405. Price, $2.50. Philadelphia and London: W. B. Saunders & Co. 1901.

It is not very long since we noticed the first edition of this work and expressed our opinion in regard to it. The author has in the present edition attempted to make some additions and alterations as the progress of scientific embryology should demand and to correct so far as they exist whatever errors there might have been in the earlier edition. The most extensive changes are those in regard to the formation of the placenta as it is demonstrated by the recent works of Peters and Webster. This chapter, therefore, has been entirely rewritten. New illustrations have been added, and in other respects the book has been brought up to our present knowledge of its subject.

DISEASES OF THE INTESTINES. By Dr. I. Boas, Specialist for Gastro-Intestinal Diseases in Berlin. Authorized Translation from the First German Edition, with Special Additions by Seymour Basch, M.D., New York City. With 47 Illustrations. Cloth. Pp. 562. Price, $5.00. New York: D. Appleton & Co. 1901.

This work, which has enjoyed a wide popularity in its own country and introduced to American readers in this translation by Basch, is intended as an aid to the general practitioner and surgeon. The translator has done a service to American readers by his notes, which are inserted in brackets throughout the text. In some particular parts, especially his statement of American ideas and references, is decidedly of service. It is probably impossible for a continental European writer to keep fully up to American work in this line, and, in most cases, the

American reader will have to supplement his work by the contributions of his own countrymen. In the present edition the translator has met this need to a considerable extent.

ELECTRICITY IN MEDICINE AND SURGERY. By William Harvey King, M.D., of New York. With a Section on Electro-Physiology by W. Y. Cowl, M.D., of Berlin, Germany, and a Section on the Bottini Operation by Alfred Frendenberg, M.D., of Berlin, Germany. Pp. 504. Illustrated. Price, $3.50 net.

This work is divided into Part I, having pages 1 to 250, and Part II, with pages 1 to 296, which method of paging appears awkward to the reader. A large amount of information is gathered together, but the negligent proofreading is "an eyesore." For instance there occur in Part I the following: Drganic, p. 15; portible battery, p. 59; seperate, p. 73; accumilator, p. 79; vacuua, p. 97; ulner nerve, p. 127; in Part II, lemoderma (leucoderma?), p. 259, but lemorderma in the index; pruritis, p. 260; lumpus vulgaris, p. 263. It contains a detailed account of the Bottini operation for prostatic hypertrophy.

DISEASES OF THE NOSE AND THROAT. By F. De Havilland Hall, M.D., F.R.C.P. Lond., President of the Laryngological Society of London, and Herbert Tilley, M.D., B.D. (Lond.), F.R.C.S. Eng., Surgeon to the Throat Hospital, Golden Square. Second Edition, with 2 Colored Plates and 80 Illustrations. Cloth. Pp. 605. Price, $2.75. London: H. K. Lewis. Philadelphia: P. Blakiston's Son & Co.

The second edition of this work contains an increase of about 50 pages over the first edition. The subject matter is of uniform excellence. Treatment, both medicinal and surgical, is fully and thoroughly described. The various articles on diseases of the accessory sinuses have been revised, brought up to date, and gone into more in detail than in the first edition. The illustrations number 80, and two colored plates. In appearance the book is about the same as the first edition.

A MANUAL OF BACTERIOLOGY. By Herbert U. Williams, M.D., Professor of Pathology and Bacteriology in the Medical Department of the University of Buffalo. With 89 Illustrations. Cloth. Pp. 290. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This little work gives in the smallest possible space the leading facts in bacteriology that the physician would need and a little more which he may learn if his needs and inclinations lead him to go further. It is a condensed manual of medical bacteriology and as such will continue to prove useful to many active physicians who do not feel inclined to go more deeply into the matter and study larger and more exhaustive textbooks. The fact that it has passed through two editions within three years shows that it has met a want.

THE MEDICAL NEWS VISITING LIST. 1902. Thirty Patients per Week. Pp. 192. Seal Grain Leather. Price, $1.25. Thumb-letter Index, 25 cents Extra. Philadelphia and New York: Lea Brothers & Co. 1901.

This visiting list for 1902 just received is gotten up in the excellent manner that has characterized preceding issues. The work includes the usual large amount of practical information, tables, etc. It is printed on fine tough paper, durably and handsomely bound, with a ready-reference thumb letter index.

PHYSICIAN'S POCKET ACCOUNT. By J. J. Taylor, M.D. Book and Leather Case. Pp. 208.

This convenient and complete account book consists of pages for index, balance due brought forward from former book, account of professional services rendered, record of births, vaccination, etc., cash account. Each page has 31 to 36 lines. It is not limited to any particular months or year, and can be begun or closed at any time.

Societies.

COMING MEETINGS.

Indian Territory Medical Association, Muskogee, Dec. 3-4, 1901.
Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Cass County (Texas) Medical Association.—The physicians of Cass County met at Atlanta, November 9, and organized this Association with the following officers: Dr. O. M. Connerley, Atlanta, president, and Dr. R. L. McClung, Atlanta, secretary.

Vermilion County (Ill.) Medical Society.—The annual meeting of this Society was held in Danville, November 8. Dr. J. Milton Guy, Danville, was elected president, Dr. Buford Taylor, Westville, vice-president, and Dr. Elbert E. Clark, Danville, secretary-treasurer.

Henderson County (Ill.) Medical Association.—This Society met at Oquawka, November 5, revised the county fee-bill and elected Dr. Isaac F. Harter, Stronghurst, president; Dr. Coleman J. Eads, Oquawka, vice-president, and Dr. William D. Henderson, Biggsville, secretary.

Hartford (Conn.) Medical Society.—At the meeting of this Society, November 4, resolutions were passed of appreciation of the character of the late Dr. William Hudson, of grief at his death and of condolences for his family. Dr. Nathan Mayer was elected vice-president to succeed Dr. Hudson.

Mahaska County (Iowa) Medical Association.—The third effort of the physicians of this county to organize a medical society was made, November 6, at Oskaloosa, when Dr. Joseph F. Coveny was made temporary chairman, and Dr. Lewis A. Rodgers, temporary secretary, both of Oskaloosa.

Students' Obstetrical Society of the Louisville Medical College.—This Society was organized, October 31, at the residence of Dr. Walter B. Gossett. The intention is to hold monthly meetings at each of which a paper will be read and discussed. Dr. Walter B. Gossett was elected president; C. E. Ryan, vice-president; M. A. Gantt, secretary, and W. F. Burnett, treasurer.

East Los Angeles (Cal.) Physicians' Club.—At the recent meeting of this Society for organization, the following were stated as its object: Mutual improvement, the encouragement of social intercourse and harmony among its members; the elevation of professional character and the adoption of a uniform fee-bill. Dr. Eber S. Carlisle was elected president and Dr. Robert C. Dundas, secretary and treasurer.

Bucks County (Pa.) Medical Association.—At the annual meeting of this Association, held at Doylestown, November 6, the following officers were elected: Dr. Howard A. Hellyer, Penn's Park, president; Drs. Henry Lovett, Langhorne, and Alfred E. Fretz, Sellersville, vice-presidents, and Dr. A. F. Myers, Blooming Glen, secretary and treasurer. The next meeting will be held in Newtown in February next.

Medical Society of the City Hospital Alumni, St. Louis.—This Society held its decennial celebration November 4. More than one hundred sat down to a repast at Faust's. Besides the active local members of the Society, there were in attendance, Dr. E. H. Gregory, one of the Nestors of the local profession, Dr. Julius Kohl, Belleville, Ill., the oldest member of the Society, and Dr. T. Holland, Hot Springs, Ark. Brief addresses were made by Drs. Gregory, Kohl, Tuholske, Grindon and Lewis.

Grundy County (Ill.) Medical Society.—The physicians of Grundy County met at Morris, November 1, and organized this Society as a branch of the State Medical Society with the following officers: Dr. Austin E. Palmer, Morris, president; Dr. John E. Brock, Coal City, vice-president; Dr. H. Milton Ferguson, Morris, secretary, and Dr. W. E. Walsh, Morris, treasurer. Drs. John J. Brinckerhoff, Minooka, Frank A. Palmer, Gardner, and O. Prescott Bennett, Mazon, were selected as a board of censors.

Franklin County (Pa.) Medical Society.—This Society, at a meeting held at Mercersburg, elected the following officers: Dr. P. Brough Montgomery, Chambersburg, president; Drs. Oliver P. Stoey, Roxbury, and J. W. Croft, Waynesboro, vice-presidents; Dr. John J. Coffman, Scotland, recording secretary; Dr. H. C. Devilbiss, Chambersburg, corresponding secretary; Dr. David Maclay, Chambersburg, treasurer; and Dr. H. G. Chritzman, Welsh Run, censor. After the business and scientific meeting a banquet was given at the Mansion House.

Medical and Surgical Faculty of Maryland.—The Section on Neurology and Psychology was inaugurated, November 8, with Dr. Henry M. Hurd as chairman, and Stewart L. Paton as secretary. Dr. Paton showed a case of dementia precox, Dr. George J. Preston, one of combined sclerosis of the cord, and Dr. Henry M. Thomas, one of lead paralysis with double wrist-drop. The Section on Clinical Medicine and Surgery was successfully inaugurated, November 1, with Dr. Louis McL. Tiffany as chairman and Dr. John Ruhräh as secretary. Dr. William Osler exhibited a case of scurvy, and Dr. Ruhräh gave some lantern demonstrations of syringomyelia, etc.

Medical Graduates' Society of Bishop's University, Montreal.—At the meeting of this Society, held in Montreal, November 7, the following officers were elected: Dr. Francis W. Campbell, Montreal, honorary president; Dr. George Fisk, Montreal, president; Drs. F. J. Hackett, Montreal, and Dr. Grosvenor L. T. Hayes, Graniteville, Vt., vice-presidents; Dr. William Burnett, Montreal, secretary-treasurer; Drs. F. R. England, Rollo Campbell, J. J. Benny, George Hall, J. M Jack and F. O. Anderson, resident council, and Drs. Charles D. Ball, Santa Ana, Cal., Albert F. Longeway, Great Falls. Mont., Robert A. Walker, Menominee, Mich., Dr. E. E. Bronstorph, Jamaica, W. I., Dr. Rollin C. Blackmer, St. Louis, Mo., and Dr. Casey Wood, Chicago.

Lenawee County (Mich.) Medical Society.—The first scientific meeting of this Society was held November 5 at Adrian, at which papers were read by Dr. N. D. Yale, Deerfield, on "Progressive Pernicious Anemia," and Dr. C. Kirkpatrick, Adrian, on "Pneumonia." Permanent officers were elected as follows: President, Dr. Daniel Todd, Adrian; vice-president, Dr. George Howell, Tecumseh; secretary and treasurer, Dr. David L. Treat, Adrian. Lenawee County has a population of 50,000, with nearly 75 physicians, and yet this is the first medical society ever organized in the country. It is the result of the effective work of the president of the State Society, Dr. Leartus Connor, and the secretary, Dr. A. P. Biddle, through the local aid of Dr. David L. Treat.

Ohio Society for the Prevention of Tuberculosis.—Under the auspices of the State Board of Health, Dr. C. O. Probst, its secretary, being the prime mover, this society was formed at Columbus, November 15, by 150 physicians and laymen. This Society is formed to fight in every known and feasible way the disease that kills 6000 people in Ohio yearly. An early move is the establishment of a State Hospital for Consumptives. This will be used for all cases in which there is a possible chance for cure. An isolation hospital for incurables is to be built in every county. A subordinate society is to be formed in every county. Free lectures are to be given in colleges, schools, and to the public generally on the danger of contagion from consumptive patients and on the care of consumptive patients. Consumptives are to be separated from other inmates in public institutions. Efforts will be made to establish an anti-spitting crusade. Dr. Byron Stanton, Cincinnati, presided at the first meeting. Dr. C. O. Probst read a paper on the aims of the society, after which it was organized by the election of the following officers: President, Ex-Congressman Joseph H. Outhwaite, Columbus; vice-president, S. S. Knabenshue, Toledo; treasurer, R. M. Rownd, Columbus; secretary, Dr. A. Timberman, Columbus; financial secretary, Dr. B. F. Lyle, Cincinnati; board of directors for three years, Dr. Byron Stanton, Cincinnati; Dr. C. O. Probst, Columbus; Dr. N. C. Tobey, Toledo; for two years, Dr. G. A. Doren, Columbus; Judge Gilbert H. Stewart, Columbus; Dr. A. H. Freiberg, Cincinnati; for one year, Dr. P. M. Foshay, Cleveland; Dr. W. J. Conklin, Dayton; Prof. Cady Staley, Cleveland. The annual meetings of the Society will be held in June.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fourteenth Annual Meeting, Held in Richmond, Va., Nov. 12, 13, 14, 1901.

President Dr. Manning Simons, Charleston, S. C., in the Chair.

First Day—Morning Session.

Laceration of the Cervix and Its Consequences.

Dr. E. S. Lewis, New Orleans, said that lacerations of the cervix were productive of more functional and organic disturbances than had heretofore been supposed. The fascination of abdominal surgery and brilliant results achieved and the increasing scope of this work had, in a measure, diverted attention from these minor injuries which, when neglected, proved most serious, and had an important bearing upon the health, happiness and life of women. The author's intention was simply to awaken attention to the importance of the topic which had, in a measure, been lost sight of, and to emphasize what had been so emphatically and graphically described by Emmet. There was no question as to the course to be pursued by the accoucheur in lacerations of the perineum, although of less significance than tears of the cervix as to final results. In moderately recent cases the classical Emmet operation could not be improved upon; yet in certain long-standing cases, where the cervix had become thickened enormously from hyperplasia the Emmet operation would fail to afford relief. In such cases he had used the Schroeder operation or a modification of it with gratifying results.

Vaginal Puncture or Incisions for Puriform Disease or Exploratory Purposes Are Unsurgical Procedures.

Dr. Joseph Price, Philadelphia, read a paper with this title. He had been asked frequently during the past year to see and reoperate on patients upon whom vaginal incisions or puncture methods had been practiced. In three very recent operations for the removal of pelvic contents puncture and vaginal incisions complicated the sections that would have been otherwise comparatively easy. The vaginal fixation, closure of the openings, refilling of puriform or serous sacs, were only local complications; the general condition of the patient became rapidly unfavorable for favorable abdominal work. He was satisfied that the ancient methods of evacuating puriform accumulations, that of cautery or caustics, was much more scientific than the present methods of vaginal incision. Operators, who practiced vaginal incisions, never know the precise pathological conditions; they puncture or incise a puriform accumulation and guess at a name, ovarian abscess, pus tube, or pelvic abscess; if the fluid evacuated was serous in nature, they called it encysted serous effusion. The probabilities were that it was a dropsy of the tube or hydrosalpinx. Puriform tubes as large and tortuous as one's flexed thumb should never be overlooked or punctured. The error of puncturing an ovarian abscess, or small dermoid, two conditions very commonly found, and both easily enucleated, should never be made. He had never known a patient cured by the methods referred to. The general condition of patients, the rapid restoration to health following clean extirpations from either above or below were striking when compared with the patients traveling around, seeking relief and health, after the timid, incomplete procedures under discussion.

Dr. George H. Noble, Atlanta, stated, as a contrast to the experience of the essayist, that he had treated six cases by vaginal incision and drainage, with very good results, but favored operating through the abdomen and of doing more complete operations where the conditions of the patients permitted.

Dr. Rufus B. Hall, Cincinnati, Ohio, said he had practiced vaginal puncture and drainage in cases in which it was not prudent to do more radical operations on account of the desperate condition of the patients. He had always emphasized the fact to the patient and friends that this operation was not done for curative purposes; that it was a makeshift, and that a more radical operation by the abdomen would have to be done later to afford permanent relief. It was his experience that a large majority of such women returned for radical operations, sooner or later.

Dr. W. D. Haggard, Jr., Nashville, said there were patients who completely recovered from vaginal incision and drainage, and cited an interesting case in point. He fully expected to do an abdominal section in this case to remove a diseased tube and ovary, but apparently the disease had expended its course.

Dr. Lewis S. McMurtry, Louisville, spoke of the great change that professional opinion had undergone of late years in regard to the operative treatment of pus in the pelves of women. He referred to the early history of the vaginal operation and its great popularity for years; but now French and German operators were resorting to the suprapubic route in dealing with puriform collections in the pelvis. These operators were compelled to adopt this route as their patients only partially recovered from vaginal incision and drainage.

Dr. Edwin Ricketts, Cincinnati, did vaginal puncture in a case in 1886. After her first delivery the woman had a severe pelvic inflammation with pus, and her condition was such as to contraindicate an abdominal operation. She recovered and subsequently bore four children. When patients did not get well from vaginal puncture and drainage, the abdomen should be opened and the diseased appendages removed.

DR. GEORGE S. BROWN, Birmingham, held that vaginal puncture and drainage in some cases should be practiced as a life-saving measure. He mentioned six cases that he had in the last four or five years in young or recently married women of gonorrheal infection of the tubes. In these he resorted to vaginal puncture; most of the patients were treated as emergency cases, and so far as he knew, only two or three of them had been reoperated.

FIRST DAY—AFTERNOON SESSION.

Treatment of Pelvic and Abdominal Tumors Complicating Pregnancy, with Report of Cases.

DR. RUFUS B. HALL, Cincinnati, read a paper with this title. The conclusions arrived at from the four cases narrated may be summarized briefly, as follows: In the very small percentage of cases in which malignant tumors are the cause of the obstruction, they should be dealt with according to the well-established principles of modern surgery. The operation should be made at once without any reference to the child, if by so doing there is any additional chance of saving the life of the mother. If the ovarian tumor is thin-walled, of large size and rapid growth, and the patient is not near her full term of gestation, an operation should be advised, even if the uterus is below the tumor. If the tumor is thick-walled and of slow growth, is not causing much, if any, inconvenience, and rides above the enlarged uterus, an operation is not urgently demanded. If the tumor is small in size, is situated below the uterus, and is fixed either by adhesions or impaction an immediate operation is demanded. Tapping the tumor for temporary relief should not be done. In fibroid tumors of the uterus associated with pregnancy, where there are but one or two large nodules, and they are located in the upper half of the uterus, an operation should be advised only in rare instances. These patients can be delivered safely and be operated later, if necessary. If the tumor is below the pregnant uterus and a large nodule blocks up the passage, an operation should be advised and made early. Myomectomy is usually not to be considered in these cases on account of the increased blood supply. The writer would advise it only when an exceptionally favorable tumor for this method is encountered.

DR VIRGIL O. HARDON, Atlanta, said that his conclusions were essentially the same as those enunciated by the essayist. He mentioned two cases of ovarian tumor complicating pregnancy in which he thought it advisable to operate. These cases were singularly alike; both were primiparæ, and during the fourth month of pregnancy. The tumors were removed; the women recovered, went to full term, and the children are living. He had seen many cases of fibroid tumors complicating pregnancy; but where the fibroid is so situated as to exert no pressure on the uterus and thereby not interfere with pregnancy, he thought there was no indication for operation in such cases until pregnancy has been completed.

DR. GEORGE H. NOBLE, Atlanta, said that removal of a fibroid tumor complicating pregnancy should be based upon mechanical obstruction to labor. Ordinarily, of course, there were exceptions, as a twisted pedicle, inflammatory conditions, etc.; then the tumor should be removed. If the tumor or tumors were in the lower segment of the pelvis in advance of the fetus, it was necessary to remove them or the uterus must be evacuated, and as these tumors can be removed with considerable safety and with a chance of saving the life of the child, it was a feasible operation. Dr. Noble narrated cases in point.

DR. W. D. HAGGARD, Nashville, cited a case which he saw with Dr. Fort in which a myomectomy was done. The patient was a colored woman, who had been married ten years, and was sterile. She was three and a half months advanced in pregnancy, and had two subserous fibroid tumors, one about the size of an orange on the right side on the anterior face of the uterus, the other one about the size of a baby's head on the left side, near the fundus. Both tumors were removed easily without any deleterious effects; the woman was subsequently delivered of a full-grown, living child.

Unique Case of Extrauterine Pregnancy.

DR. H. TUHOLSKE, St. Louis, Mo., contributed a paper with this title. The following is a résumé of the case: Tubal pregnancy (ampullar) of the right side. Tubar abortion with complete extrusion of the gestation sac, unruptured and containing fetus; hemorrhage and position carried the sac up to the diaphragm between the right lobe of the liver and upper end of the kidney. Implantation in the parietal peritoneum of the diaphragm as far forward as the attachment of the coronary ligament and in the liver from its upper border to the transverse fissure; down the diaphragm posteriorly and in the upper end of the kidney. Establishment of placental connections, allowing the development of a well-grown living child and pushing the liver in its growth towards the left and turning it upon its axis, with the coronary ligament as a fixed point until the right margin of the liver became the anterior. Histological examination showed original implantation in the ampulla of the right tube, and the formation of a placenta by efficient transformation of the peritoneum and the liver tissue adjacent. The diagnosis of the case from its history was confirmed by clinical, operative, pathological and histological evidence.

The Surgical Treatment of Painful Menstruation.

DR. HENRY D. FRY, Washington, D. C., in this paper stated that pain should not occur at the menstrual period in a healthy woman with healthy pelvic organs. This dual relation between the general health and the generative organs must be constantly kept in mind. As these sufferers are nearly always young girls or unmarried women, the indications must be clearly manifest. The character and severity of the pain, its duration and the condition of the patient during the intermenstrual period must be considered. What results can be expected from surgical treatment? In the discussion of this subject before the last meeting of the American Gynecological Society, the reflected opinions presented a gloomy picture for the woman. His object in presenting this paper is to protest against that verdict rather than offer any original method. His experience has been just the opposite. Failure to give relief has been due, as a rule, to some complication the removal of which subsequently resulted in cure. The line of treatment followed with such satisfactory results is that pointed out in the main by Gill Wylie: First, thorough dilatation of the cervical canal, then the endometrium is gone over carefully with the sharp curette; irrigation and often a second curettage; the application of pure carbolic acid; irrigation and dilatation repeated, if necessary. A Wylie drainage plug as large as will readily pass is inserted into the cervical canal and kept in position by a Smith pessary. For a number of years he was accustomed to leave the plug *in situ* six days, but following the suggestion of Wylie, he now allows it to remain from three to six weeks. He usually keeps the patient in bed two or three weeks after the operation, and if no discomfort be experienced, permit her to get up and go around wearing the plug several weeks longer. He believes the use of the hard rubber plug does much to aid in the permanency of the relief obtained. It causes the formation of a cicatricial ring of tissue at the point of constriction which insures patuleney. He had not seen any bad results follow its use. In a few cases it causes pain, and on that account must be removed sooner than the time mentioned. He attributes the failure of those who deplore their results to the omission of some important point in the technique of the operation. For instance, they simply dilate the cervix or dilate and curette. For all necessary purposes dysmenorrhea can be divided into two classes, simple and complicated. The simple comprises about 80 per cent. of the cases, and the treatment described cures or greatly relieves three out of every four. The conditions usually found on examination are as follows: The external genitalia are undeveloped; the vagina, cervix and uterus are small. There is stenosis of the cervical canal and endometritis. The uterus is normal in position or one of exaggerated anteflexion; it is movable and the appendages are healthy. The accompanying endometritis is chronic and due to deficient drainage of the cervix uteri in consequence of stenosis of the cervical canal. The undeveloped condition of the generative organs in young women is very common and parallel to deficient growth of the mammary gland and its consequent failure to perform the

function of lactation. The second class comprises the cases in which some complication exists. It may be displacement, small fibroids in the body of the uterus, or disease of the tube or ovaries. These complications must be recognized and corrected. In a very small proportion of cases, as in cirrhotic ovaries, operators are driven to produce the menopause artificially. In such cases he believes it advisable to amputate the uterus at the same time, as the subsequent reflex nervous symptoms are diminished and the period of suffering shortened.

Repair of a Complete Laceration of the Perineum in a Girl of Nine Years.

Dr. H. A. Royster, Raleigh, N. C., reported this case. The laceration was produced by the finger of the obstetrician at the patient's birth. The patient was a well-nourished girl of 9 years. At her birth her perineum was torn completely through the recto-vaginal septum, and the explanation of this occurrence is stated to be as follows: The child's grandfather, a very aged physician, acted as accoucheur. Owing probably to dimmed eyesight and infirmity, a breech presentation was evidently mistaken for a vertex position and the obstetrician, introducing his finger into what he thought was the child's mouth, but which was really its vagina, exerted traction, and the result was a complete laceration of the baby's perineum. No immediate harm came from the accident, and it was resolved not to attempt a restoration of the injured region until the girl was considerably older. During the autumn of 1900 she came first under the observation of Dr. Hubert Haywood, who related the above facts and referred the patient to the speaker for operation. The parts on examination showed a quantity of dense scar tissue. The tear extended into the vagina to the depth of a half inch, and the sphincter ends were plainly seen on either side. No incontinence of feces had occurred. On Nov. 15, 1900, under chloroform anesthesia, a butterfly-shaped denudation was made in the vagina, and the exposed edges of the rectum pared, taking pains to dissect out the torn sphincters. The rectal tear was then united with catgut sutures, which were tied inside the bowel and cut short. Silkworm gut was used for closing the vaginal surfaces and bringing together the ends of the sphincter muscle. Perfect apposition was obtained and rigid asepsis observed in all the details of the technique. In spite of these precautions only partial success resulted, due to the fact that the patient's bowels became unmanageable just at the beginning of the operation, and the denuded area was constantly and unavoidably bathed by a stream of feces. This unlooked-for disaster was brought about by faulty preparation of the patient before admission. A purgative had been administered the day before, and on the morning of the operation an enema was given, with the report that the bowels had been thoroughly emptied. The continual discharges were a source of much annoyance, but having begun it was considered best to complete the operation. At the end of two weeks it was found that the external sutures did not hold, although union of the upper part of the denuded tissue was secured. A second operation was attempted April 18, 1901. The same method of procedure was employed, but modified to suit the changed relations. The child was prepared under direct personal supervision, and no fecal contamination occurred. The parts healed promptly, and the result was perfect. The author could find no parallel to this case in the literature of the subject.

[To be continued.]

UNIVERSITY OF CHICAGO MEDICAL CLUB.

First Regular Meeting, held in the Hull Physiologic Laboratory, Oct. 21.

Dr. H. H. Donaldson was elected president, and Dr. Preston Kyes, secretary for the ensuing year.

Influence of the Valency and Possibly of the Electric Charges of Ions Upon Their Toxic and Antitoxic Effects.

Dr. Jacques Loeb stated that together with his colleagues, he had shown that sodium ions are absolutely essential for the production of rhythmic contractions in striped muscle or in the swimming-bell of a jelly-fish or the heart, and yet that a pure solution of sodium chlorid is poisonous; further, that the poisonous effects of a pure sodium chlorid solution can be overcome by adding a trace of any soluble calcium salt. While some authors had drawn the conclusion that calcium is the stimulus for the heart-beat, the speaker had proved by a series of experiments on the development of the eggs of a marine fish, Fundulus, that this interpretation of the rôle of calcium in the heart-beat can not possibly be correct. The eggs of Fundulus develop in sea water, which is chiefly a solution of sodium chlorid and which has approximately the concentration of a five-eighths normal NaCl solution. The same eggs, however, develop in distilled water and even in redistilled water, thus showing that no ions of any kind are necessary for their development. Yet if these eggs are put into a pure NaCl solution of the strength in which they develop normally in sea-water, not a single egg can form an embryo. If, however, a soluble calcium salt be added, all the eggs form embryos and the embryos develop. This proves conclusively that calcium can not be considered a stimulus for the development of the eggs, as the eggs develop just as well in distilled water. The calcium ions can only perform the function of antagonizing the poisonous effects of the sodium ions.

It occurred to the speaker that this fact might be only a special case of a more general law. Sodium ions are univalent, while calcium ions are bivalent. He tried to determine whether or not he could produce the same effects by the addition of any other bivalent ions besides calcium. He found, indeed, that the addition of a trace of any of the following ions—strontium, magnesium, barium, zinc, iron, cobalt and lead—acted in the same way. He found, moreover, that the addition of a trace of a trivalent metal ion had also antitoxic effects. For instance, when a small amount of aluminium chlorid or chromium sulphate was added to a five-eighths normal sodium chlorid solution, a number of eggs were able to form embryos.

But not only a pure sodium chlorid solution of a certain concentration was poisonous, but a pure solution of any salt was found to be poisonous. For instance, a pure solution of lithium chlorid, ammonium chlorid and potassium chlorid of a certain strength was also poisonous. It was found that a solution of any of these salts which prevented the development of an egg could be rendered harmless by adding a small amount of all or some of the bivalent metal ions mentioned above. A pure solution of any of the salts of a bivalent, *e. g.*, $CaCl_2$, $MgCl_2$, etc., was also poisonous. Such solutions could be rendered harmless by the addition of a comparatively large quantity of a univalent metal ion or a very small quantity of another bivalent or trivalent metal ion. While the poisonous qualities of a solution of any salt could be annihilated by the addition of small quantities of a trivalent or bivalent metal ion or large quantities of a univalent metal ion, the anions were found to have no antitoxic effects whatsoever.

So far as the interpretation of these phenomena is concerned, the speaker pointed out the fact that such an influence of the quantity and sign of the electrical charge of ions has been found by physicists in connection with the phenomena of coagulation and the viscosity of colloidal solutions.

Dr. Loeb drew attention to the fact that from the point of view of the pathologist these experiments are of special interest as some of the observations are very analogous to the observations made by Ehrlich and his pupils in their study of antitoxins and immunity. Two facts of this character may be mentioned: 1. There is a numerical relation between the NaCl used and the amount of Ca-ions needed to counteract the poisonous effects of the sodium ions. The greater the concentration of the sodium salt present, the more calcium is required to render the solution of the sodium salt harmless. 2. In some cases the calcium (or strontium, etc.) can only produce its antitoxic effects if a trace of a second class of ions (for example, potassium) is present. This proved to be the case in experiments on the eggs of the sea-urchins. Neither the potassium alone nor the calcium alone were able to counteract the poisonous effects of a pure NaCl solution.

but both together were effective. The potassium ions act in this case like the "immune body" in Ehrlich's experiments.

A Case of Myiosis Intestinalis in Man.

DR. ALBERT PEACOCK reported this case. The patient, who came in from the country, complained of abdominal distension and excessive appetite. The existence of tapeworm was suspected. On examination of the feces the fly-larvæ were discovered. Specimens of the larvæ were placed under the microscope and demonstrated to the Club.

DR. L. F. BARKER said the case reported is of unusual interest on account of its rarity. Invasion of the human body by larvæ of insects has frequently been reported; the nasal pharynx, the external ear, the skin and open wounds and ulcers, are most frequently involved. The existence of larvæ in the stomach and intestines of human beings occurs, however, much less frequently.

Invasions of the body by fly-larvæ are most common in hot countries, and it is in the text-books of tropical diseases that we find the fullest accounts of them. Scheube in the new edition of his work, distinguishes three principal varieties: 1, those due to larvæ of Lucilla macellaria, so-called "screw worms"—these appear to be allied, if not identical with the Musca anthropophaga and the Sarcophila Wohlfahrti of other authors; 2, Dermatobia noxialis, or so-called beef worm, identical, in all probability, with the Oestrus Guildingi of Hope—these give rise to boils in the skin; 3, Ochromyia anthropophaga, the larvæ which so often affect the skin of natives of Senegambia.

Sandahl of Stockholm has reviewed the bibliography of myiosis intestinalis with special reference to the cases occurring in the Swedish literature. He finds instances where the larvæ are those of flies (myiosis), others where the larvæ are those of beetles (cantharіosis), and again others where the larvæ are those of butterflies (scolechiosis). He lays most emphasis upon the case carefully reported by Lampa in 1887. In this instance the patient on July 4 discovered creeping larvæ in the stools, which were recognized by Lampa as insect larvæ. They were washed in water, put into a box containing some earth and given food. Two weeks later several adult flies developed, and these were recognized by Holmgren as belonging to the species Aricia (Holmalomyia) scalaris and A. manicata. Lampa believed that the larvæ had their origin in the eggs deposited by flies on cold food which had been insufficiently protected and which was eaten without re-cooking.

Care must be taken to distinguish true myiosis intestinalis from instances where fraud has been perpetrated. In the older literature several remarkable instances of the latter type are recorded. Thus Acrel, in 1799, refers to a woman of 30 who, during two years, voided no less than 130 Ascaris lumbricoides, pieces of Tænia solium, and innumerable Oxyures vermiculares, in addition to 265, partly living, partly dead, Staphylinids of various kinds and several larvæ, among others, those of Tenebrio molitor.

The specimens presented by Dr. Peacock show some eleven segments, and at one border of each segment there is a narrow cuticular band covered with minute but very sharp thorns.

An attempt is being made to secure some of the living larvæ and to bring them to development in order that the species here concerned may be determined. Some idea of the way in which the parasite entered the body may then be gained.

Regular meetings of the Club will be held the first and third Monday evenings of each month.

CHICAGO ACADEMY OF MEDICINE.

Regular Meeting, held Oct. 11, 1901.

Dr. De Laskie Miller in the Chair.

Fracture of Inner Occipital Table.

DR. W. G. STEARNS reported a case of "Fracture of the Inner Table of Occipital Bone, with Cerebral Concussion and Contusion, Involving the Base of the Temporo-Sphenoidal and Frontal Lobes." An obese, well-nourished man, 40 years of age, was admitted to the Samaritan Hospital with the history of having been thrown backwards from a cable car, striking his head on the pavement. He was semi-conscious, but easily aroused and talked connectedly. He recognized friends, but had no knowledge of the accident. The scalp was cut one-half inch below the junction of the occipital and parietal bones in direct line with the sagittal suture, exposing the torn epicranium. The pupils reacted sluggishly; the left pupil was a trifle less contracted than the right. There was no loss of power in the limbs, and the reflexes were normal. There was intense pain in the frontal region from the time of injury, and persistent vomiting continued for forty-eight hours, when he was removed from the hospital. For a week after the injury he was in a dazed semi-conscious state, and often complained of severe headache. As he regained consciousness, aphasia and amnesia became evident. There was much irritability and some incoherence. He was admitted fourteen days after the injury to the Oakwood Sanitarium, where he was found to be extremely restless, with grandiose ideas and speech. His memory for recent events was defective, and his answers were not relevant until questions were several times repeated. His gait was reeling and uncertain. His handwriting showed frequent substitution of letters, but no tremor. This condition continued until the evening of the sixteenth day after the injury. He died on the morning of the seventeenth day after the injury, and was found lying on his left side, left leg, thigh, elbow, wrist and fingers being semi-flexed and flexed.

As the patient was carrying large amounts of accident insurance, a necropsy became necessary, and was made by Drs. Stearns and Kiernan. This revealed a thin partially organized clot loosely adherent to the inner surface of the dura over the convexity of the left frontal lobe, and extending downward anteriorly. Upon removing the brain this clot was found to extend downward, covering the entire left middle fossa, and to be from one-eighth to three-sixteenths of an inch thick in its thickest portions. A similar clot was found covering the floor of the left middle fossa, and another covering the upper surface of the left tentorium. Slight mottlings of similar but much thinner clots were found in the right middle and anterior fossæ, and a few were also found in the posterior fossæ. The cerebrospinal fluid was moderate in amount and bloody. The pia was slightly opaque over the convexity, and the median portion of the basal surface. It strips freely except over areas of softening, where it is adherent. The basal arteries and the cranial nerves are normal. The cortex presents an area of softening on the anterior tip of each frontal lobe extending backwards along the basal surface, including that portion adjacent to the longitudinal sulcus. The lesion is deeper and more extensive in the left lobe. Also an area of softening along the anterior portion of the basal surface of each of the temporo-sphenoidal lobes. Convolutions deep and otherwise normal. The fluid of the ventricles was under but slight pressure and was blood-stained. Ependyma normal throughout. All fiber tracts, basal ganglia, cerebellum, pons and medulla normal. On stripping the dura from the base of the skull there was found a linear fracture of the inner table, beginning at a point one-half inch to the left of the median line about two and one-half inches above the torcula, extending downward and to the right, crossing the median line at a point midway between the torcula and the foramen magnum, terminating in the foramen magnum, just to the right of the median line. A second linear fracture, also of the internal table, joined the first at an acute angle at its upper extremity, coursing to the left at first in the line of the lambdoidal suture, then going below it and passing just above the base of the petrous portion of the temporal bone, terminating at about the middle of the outer surface of the temporal fossa.

That portion of the bone on the surface opposite to that which receives the impaction is first put upon tension, therefore first fractured, while the surface receiving the impaction is compressed until its foundation, the underlying medullary portion or the opposite portion, gives way to the strain, and allows the stress to come upon it when, in turn, it is fractured. It is the external surface of a rib which receives an impact from

a flat body, therefore the inner surface first placed upon strain is first fractured, and if force be not too severe, this is the only portion fractured. Similarly, the external table receiving an impaction applied over a large area becomes compressed, not only beneath the area receiving the impaction, but the conical area supporting it, just as the weight resting upon a keystone is transmitted to each stone in its arch. If the force be sufficiently great, the diploë upon which it rests, or the internal table, or both, must give way before the external table can.

Dr. A. H. Ferguson stated that it was admitted in surgery that an impact received upon any part of the skull would not only produce a fracture of the inner table of the opposite side, especially if the impact was strong enough, but it was capable of producing laceration of the membranes of the brain and laceration of the brain itself. This point was clearly brought out by Bryan in experimental work on the cadaver, who found that fracture could be produced by *contre-coup*, with laceration of the membranes of the brain and severe damage to the brain substance itself. Recently Macewen, of Glasgow, had asked Dr. Ferguson whether the chisel and hammer had been discarded in surgery on the brain in the United States. Impact of the hammer in Macewen's opinion had a deleterious effect on the brain. Macewen had traced strange cerebral symptoms following the use of the hammer in a few cases. Dr. Ferguson mentioned a case in which there was severe injury to the brain, with no evidence of external fracture. Fracture, whether of the external or internal table, was the minor part of the injury. He was convinced that a case like this ought to be trephined, the surgeon removing a small button of bone in three places, one where the impact was received, one exactly opposite the frontal lobe, and when symptoms were present of pressure upon the sphenoidal lobe there was no harm in removing a little button of bone there. It was comparatively easy to ascertain whether clots were present, and these could be removed sometimes with great benefit.

Dr. Sydney Kuh had a number of years ago seen a boy, 13 years of age, who was thrown from a horse, striking on the right side of his skull. There were indications of a skull fracture, but no definite symptoms at that time which made it possible to localize a lesion. Five or six days after the injury the patient developed a very characteristic Jacksonian epilepsy, which was limited to the facial muscles and to the right side, that is, on the same side on which the injury had occurred. The condition of the patient became so grave that it seemed very essential to do something in order to prevent death. Dr. Steele was called in and trephined over the left focal area (the face center), and found in that region an area of softening not larger than a dime. The opposite side of the skull, on which there was a contusion, showed a break in the integument, and gave evidence of a fracture. This case illustrated that the opposite side of the brain may be affected. Had the suggestion of Dr. Ferguson been followed in this instance, the area of softening could not have been removed with any degree of benefit to the patient, and the termination of the case would have been fatal.

Dr. Hugh T. Patrick was somewhat surprised by the trend of the discussion, since he had supposed the view was universally accepted that an injury or blow of the head was apt to cause more trouble on the opposite side than on the side on which the blow was received. This was particularly true of injuries inflicted with large bodies. A quick, sharp blow from a small body, which resembled a projectile, was more apt to cause trouble at the point of impact, but it is particularly those cases in which the individual falls, striking upon the head, or in which a large body falls upon the individual, where the injury of the brain is more diffused and apt to be found in localities other than at the point of impact. Some years ago the speaker showed at the Chicago Medical Society the brain of a man who, while intoxicated, fell and shortly became comatose. Dr. Patrick saw the case with a surgeon. Although patient was profoundly comatose, it was evident that one side of the body was more paralyzed than the other. An operation was undertaken, the surgeon being guided by the focal symptoms. The point of impact was not discovered until, at the necropsy, a clot was found and a considerable amount of it removed. At the postmortem examination a severe injury of the brain was found upon the side opposite the point of impact. But upon the same side of the brain there was also a larger clot, the one on the side where the injury was more severe, being not only a large superficial clot, spreading over a considerable area, but it burrowed deeply into the brain. This part of the clot was not removed.

Dr. Patrick pointed out that unless a linear fracture happened to rupture a large vessel, which was not enclosed in bone, or unless the fracture involved a foramen through which passed a cranial nerve, linear fracture of the skull was quite as harmless as a scalp wound. Whether linear fracture was found postmortem or diagnosed during life was a matter of small import, forensic or otherwise. The linear fracture in the case reported by Dr. Stearns had nothing to do with death. He disagreed with Dr. Ferguson and claimed that a safe rule, surgically speaking, in such cases was to be guided entirely by focal symptoms, not by point of impact of the injury, nor by any laceration, or one of the thin spreading hemorrhages over the surface.

Dr. Edward H. Lee said that linear fractures of the inner table did not give rise to symptoms except where lesion of some blood vessel occurred. The blood vessel most frequently injured in such cases was the middle meningeal. Its injury was frequently associated with a fracture of the inner table, so that a bending fracture of the skull resulted in the occipital region, which produced a linear fracture of the inner table, associated with basal fracture. The basal fracture was in direct communication with the lesion. He could not see how fracture of the inner table of the opposite side of the skull could be produced from mechanical factors. This seemed to him an impossibility. He did not think cases existed to show that such lesions resulted. Operative intervention in such cases was absolutely contraindicated. He had treated many skull cases in the last ten years, but unless there were absolute indications for opening the skull, he did not do so. He recalled four or five cases at the Alexian Brothers' Hospital, in which there were depressions of the skull. In a case of quite extensive compound fracture of the skull, he simply relieved the depression. In three others, two of which were children, he left them alone. He did not even relieve the depression, although it was quite marked at the time. These patients had done well since. In the absence of focal symptoms, it was bad surgery to interfere where there were no other absolute indications. While these lesions might be followed by Jacksonian epilepsy, he would rather take his chances of non-interference than to convert a simple fracture into a compound one, exposing a patient who was suffering from such a severe cerebral lesion, possibly associated with a fracture of the base to serious after-results in consequence.

Necessity of Exact Diagnosis in Prostatic Operations.

Dr. Louis E. Schmidt, to obtain a clear view of the subject, classified all cases under three large categories: 1, urinary retention due to prostatic changes may occur when there are alterations in the prostatic urethra proper; 2, when the cause is just on the border between urethra and bladder; 3, when the pathologic changes in the gland impair or completely abolish the functions of the bladder. First, it is a well-established fact that the prostatic part of the urethra sometimes becomes greatly obstructed, so that urination becomes impossible. It may be due to a nodular growth of the urethral part of the prostate compressing the urethral walls, or causing a tortuous passage in the same. It is readily understood in these cases that every operation which involves that part of the prostate within or adjoining the bladder would not result favorably. Examination per rectum shows these nodules just within the anus, covering or only partly covering the rectal surface of the gland. The nodules may be positively diagnosed with metal instruments per urethra. It is an absolute necessity to remove these mechanical obstructions to effect good results. Second, the type of obstruction between bladder and

urethra, i. e., that borders on the internal urethral orifice, may be either a symmetrical thickening or enlargement of the prostate as far as the parts encircle the internal urethral opening or a partial enlargement of single lobes. All these changes have in common that the obstacle to urination is a more or less complete barrier, practically separating the trigonum from the urethra. An operative success is to be sought for in a method by which this barrier is completely removed or is severed to such an extent that again free communication between the *bas fond* of the bladder and urethra is made. A correct diagnosis without incising the bladder can only be made with the cystoscope. If the surgeon confines himself in such cases to the typical Bottini incision, the result will always be incomplete. It is necessary to make a large number of incisions into the barrier or to make a complete incision of the collar-shaped hypertrophy after opening the bladder. Third, another cause for the obstruction to the flow of urine by changes in the prostate is the formation of large prostatic tumors which grow into the cavity of the bladder. In rare cases the surgeon might succeed in getting these tumors between the fingers by bimanual palpation and so make a diagnosis. This is only possible in very thin individuals with relaxed abdominal walls. A radical cure in such cases can only be accomplished by complete removal of such prostatic tumors by means of a suprapubic operation. If the general condition of the patient does not permit of such interference, nothing remains except to establish a permanent fistula. If the mechanical condition is considered in such a case, such a fistula can only be an abdominal one.

DR. JAMES T. JELKS, Hot Springs, Ark., had not been an advocate of the Bottini operation, for the reason he wanted to see what he was doing. With the old Bottini instrument the operator worked in the dark. He had been in the habit of doing the Alexander operation or a modification of it. According to the statistics of Willy Meyer, the mortality from the Bottini operation was 11 per cent. The mortality of operations done by Bottini himself was 10 per cent. The mortality from the old operation of vasectomy was 20 per cent., and that of castration 22 per cent., so that the Bottini operation had decreased the mortality rate. He had taken it for granted that the mortality following these operations had been from general anesthesia, and if Schleich's method could be used the mortality would be much less.

DR. WILLIAM L. BAUM expressed the belief that with the new modifications which have been made in the Bottini instrument, it would have a larger field of usefulness. The great objection that had always been made to this method of operating was the inability of the operator to see how far and how much destruction of tissue he was accomplishing. In cases of doubt he preferred the Alexander operation, knowing that at the present time its mortality was somewhat less, and it possessed the double advantage of being an operation whereby its steps could be watched both through the suprapubic incision and through the perineal.

DR. A. H. FERGUSON narrated a case of enlarged prostate in an old man upon whom he practiced rapid dilatation some twelve years ago. The patient has remained well up to this time. He believed that the proper use of bougies in these cases would do good, and should be judiciously tried in a limited number of instances. He advocated the perineal operation for the treatment of prostatic enlargement. He was not favorably impressed with the Bottini operation for several reasons, one of the most important of which was hemorrhage. He had lost one case by the Bottini method. He preferred the perineal route, and showed an instrument which he uses in doing this operation.

THE DENVER AND ARAPAHOE MEDICAL SOCIETY.

Regular Meeting, held Oct. 8, 1901.

Dr. H. G. Wetherill in the Chair.

Pernicious Anemia.

DR. G. E. TYLER reported the following interesting case: I. B. C., male, 47 years of age, painter, was a hard drinker for twenty years. Never had any digestion trouble until two years ago, when his appetite began to fail and he had occasional attacks of constipation. He then noticed trembling of the legs and a tremor of the right hand. He also suffered from cough and profuse expectoration. The gums and mucous membrane of the lips were bloodless. There was slight edema about the ankles. He did not appear emaciated; no lead line on the gums. Abdomen, liver and spleen were normal. Heart and lungs were negative. Knee-jerk was increased. Two small retinal hemorrhages were noticed in right eye. His temperature on admission to County Hospital, Sept. 9, 1901, was 100.2, but in a few days became normal. He was very weak and desired to remain in bed. Four days after admission he had a profuse hemorrhage from the bowels. Red blood corpuscles, 800,000; white, 4,000; hemoglobin, 40 per cent.; color index, 2.3. Two days later: red, 1,760,000; white, 7,000; hemoglobin, 42; color index, 1.2. Seven days later: red, 2,232,000; white, 8,000; hemoglobin, 42. A differential count of 1,000 white blood corpuscles gave the following percentage: polymorphonuclear, 82.3; small non-nuclear, 13.5; large mononuclear, 2.2; transitional, 1.1; eosinophiles, 0.9. Urine; no albumin or sugar, indol present. Gastric contents: HCl absent, lactic acid present, starch absent, sugar present, rennet absent, pepsin absent. Opler-Bond bacillus and sarcinæ were present. The patient showed some improvement on administration of Fowler's solution in rigidly increasing doses, which he considers to be temporary.

Papilloma of the Larynx.

DR. T. J. GALLAHER said that the small light-red tumors yield to local application. He used formalin with good results. The large red variety calls for cutting forceps. He considers intubation a dangerous procedure, as it may result in pressure necrosis or infection pneumonia. Tracheotomy has been done in young children and they were allowed to wear the tube for years. The two specimens shown were situated in the left vocal cord and at the time of their removal were of the size of a bean. The raw surfaces cicatrized promptly.

Edema of the Larynx.

DR. T. J. GALLAHER does not favor intubation in cases of edema of the larynx unless the operator is within constant reach. The tube does not engage deep enough and is therefore extruded. The necessity of frequent reintroduction of the tube increases the swelling. Edema may occur directly around the tube. Scarification and multiple punctures are disappointing. Ice pack or hot fomentations have no value. If not treated promptly and heroically edema of the larynx is fatal. If adrenalin is used it should be by spray, and kept up persistently at short intervals. Intubation should be done as an immediate measure to bridge over the time until an aseptic tracheotomy could be performed. Case: physician, 29 years of age, was suffering from acute articular rheumatism. On the eighth day at midnight he was seized with acute edema of the glottis. He introduced a tube at 1 a. m.; at 4 a. m. it was expelled and reinserted. During the next twenty-four hours the tube was expelled and reinserted six times. Recovery was prompt and uneventful.

DR. ROBERT LEVY reported two cases of papilloma in adults. One patient was hoarse for four years and was advised to come to Colorado. He removed the growth from the anterior commissure. In the other case, who suffered from great dyspnea, he performed tracheotomy. He has seen three cases in children since 1895. One was treated by intubation. The other two cases were treated for croup and asthma respectively. One was treated by intubation followed by tracheotomy, and the other by the application of salicylic and glacial acetic acid. All the cases recovered.

Specimen from an Unusual Ectopic Pregnancy.

DR. H. G. WETHERILL reported the following case: When seen the first time, she was suffering from severe pain and hemorrhage from the uterus. Her temperature was 100. In a few days all the symptoms disappeared. In the right iliac region a mass was detected by bimanual palpation. She gave history of miscarriage, which occurred three weeks previous.

Two weeks after she had another hemorrhage and severe pains; the mass increased in size. A pelvic abscess suggested itself. A vaginal incision was made and blood and clots were found. The sac was washed out with salt solution and packed with iodoform gauze. Two weeks after there was a sudden attack of intense pain and evidence of concealed hemorrhage was manifest. The abdomen was opened, but no blood found. The broad ligament was found distended to the size of a child's head, not unlike an intraligamentous cyst. When the sac was opened a full-grown fetus was found. The appendix was found grown into the mass and was removed. Before the operation the patient was very weak; indeed, her life was despaired of. As soon as the anesthetic was given, salt solution by hypodermoclysis was administered into the breasts, three pints being used during the operation. A hot salt solution was introduced into the abdominal cavity while she was placed in the Trendelenburg position so that the solution might come in contact with the diaphragm. After the operation her condition was such that it was necessary to introduce salt solution intravenously. The patient made a slow recovery, and is at present in a satisfactory condition. He thinks it was originally a tubo-ovarian pregnancy which ruptured into the broad ligament.

DR. W. P. MUNN suggested that it might have been an ectopic gestation co-existing with uterine pregnancy. Such cases are on record.

MEDICAL SOCIETY OF VIRGINIA.

Thirty-second Annual Session, held in Lynchburg, Nov. 5, 1901.

The President, DR. JOHN R. GILDERSLEEVE, Tazewell, called the meeting to order and after prayer by the Rev. F. T. McFaden, Dr. Rawley W. Martin welcomed the Society in behalf of the fraternity and the city.

DR. SMELT W. DICKINSON, Marion, delivered an address on the delusions in medicine from the days of astrology and witchcraft down to the modern time of eddyism, osteopathy and magnetic healing.

Re-organization.

THE PRESIDENT then delivered his annual address in which he congratulated the Society on meeting for the third time in Lynchburg, its birthplace. He directed the attention of the Fellows of the Society to a resolution passed in 1896 providing that members of the Society should not examine an applicant for life insurance for less than $5.00. He recommended strongly the strengthening of the bonds existing between state societies and the AMERICAN MEDICAL ASSOCIATION and suggested membership in that "grand, national, representative, medical organization." He suggested in addition that the plan adopted by the AMERICAN MEDICAL ASSOCIATION for the conservation of time should be adopted, for the obtaining of better results by devoting the morning of each day to general business, one subject and its discussion. That the first evening and succeeding afternoons should be devoted to section work, and the succeeding evenings to social functions.

DR. J. N. UPSHUR, Richmond, at the second day's session, offered a resolution to amend the clause in the constitution regarding membership as to limit it to physicians who live in Virginia, who are white and 21 years of age or over. A substitute was offered by Dr. Styll, Newport News, that the amendment take the usual course and lay over for three months, which was carried by practically an unanimous vote. A motion was adopted unanimously that all local medical societies submitting to the Code of Ethics of the AMERICAN MEDICAL ASSOCIATION should be officially recognized by the State Medical Society.

Scientific Papers.

The discussion of the morning was on uric acid and papers were read by Drs. William S. Gordon, Richmond, and Lewis E. Pedigo, Roanoke, on this subject. Gastro-intestinal therapy was the principal subject for discussion of the afternoon session, the leading paper being read by Dr. John N. Upshur, Richmond.

Report of Special License Committee.

At the evening session the report of the Special License Committee was made by Dr. J. Beverly Deshazo, Ridgeway. This committee was appointed at the last meeting of the Society to endeavor to obtain a repeal of the special license tax on physicians. It has circulated 500 pamphlets in the counties and cities of the state for signature, asking for the repeal of the law and thus far has met with practically no opposition. About 2000 physicians are in favor of the plan, but only 15 or 20 thus far have opposed it. He recommended that headquarters be established in Richmond to further the plans of the committee and private subscriptions be made to defray the necessary expense.

Delegates to American Medical Association.

The third day of the session commenced with the election of the Virginia members of the House of Delegates of the AMERICAN MEDICAL ASSOCIATION. Drs. John R. Gildersleeve, Tazewell, and Landon B. Edwards, Richmond, were unanimously elected delegates for the long and short term respectively. Drs. Livius Lankford, Norfolk, and Rawley W. Martin, Lynchburg, were elected alternates.

Election of Officers.

The election of officers resulted as follows: Dr. Richard S. Martin, Stuart, president; Drs. Livius Lankford, Norfolk, R. Sumter Griffith, Basic City, and Smelt W. Dickinson, Marion, vice-presidents; Dr. Landon B. Edwards, Richmond, recording secretary; Dr. John F. Winn, Richmond, corresponding secretary; Dr. R. T. Styll, Newport News, treasurer, and Dr. John N. Upshur, Richmond, chairman of executive committee. Newport News was chosen as the place of the 1902 meeting, and Dr. Robert L. Payne, Norfolk, was elected to deliver the annual address.

Medical Examining Board.

The Medical Examining Board elected for the ensuing year was as follows: Rawley W. Martin, Lynchburg; William L. Robinson, Danville, and Albert S. Priddy, Marion, from the state at large. From the Congressional District: Drs. Willard B. Robinson, Tappahannock; Herbert M. Nash, Norfolk; Junius E. Warrinner, Brook Hill; Otho C. Wright, Jarratt; Richard S. Martin, Stuart; Samuel Lile, Lynchburg; Robert C. Randolph, Boyce; Robert M. Slaughter, Theological Seminary; Elliott T. Brady, Abingdon, and Charles W. Rodgers, Staunton.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Prescription Writing—Continued.

II. The symbol ℞ is an abbreviation of the Latin *Recipe*, "take thou." The line drawn across the right lower part of the R is said to have been taken from the sign used to indicate Jupiter in the pagan invocations to that god. This ancient mingling of religion with the healing art serves to explain the universal acceptation by the early physicians of the symbol as an awe-inspiring superscription to their formulas.

The direct object of "Recipe" is drachmam or unciam, etc., of the ingredient, as the case may be. Consequently the names of all the ingredients should be written in the genitive case with their proper endings. These ingredients may be made up of a basis, an adjuvant, a corrective and a vehicle or excipient.

We wish to emphasize the importance of giving the names of the preparations their proper endings. The inability of the physician to write these names in the proper case and in the

proper declension, is an evidence of lack of a good preliminary education.

To illustrate, we give a prescription representing the different endings as follows:

℞.	Tincturæ nucis vomicæ	3iss	6
	Acidi hydrochlorici diluti	3i	4
	Syrupi simplicis	3iii	12
	Spiritus frumenti q. s. ad	℥ii	64

Misce et fiat mistura. Sig.: One teaspoonful after each meal.

In the above it will be seen that in the first preparation, those words ending in *a* are of the first declension and consequently their genitive ending is *æ*, while the word *nux* belongs to the third declension and the *x* (that is, *cs*) is changed into *cis* in the genitive.

In the second ingredient "acidum" is a neuter noun of second declension and therefore should be written acid*i* in the genitive and the words "hydrochloricum" and "dilutum" being adjectives must agree with the noun they limit in the proper gender and case.

In the third preparation "syrupus" being a masculine noun of the second declension, it is changed into the genitive and is therefore written syrup*i* in the prescription form.

In the last ingredient, "spiritus," although ending in *us* is not of the second declension; but, as an exception to the rule is of the fourth declension and consequently the ending does not change in the genitive.

Further dwelling upon these points, we might observe that nouns of the first declension end in *a* and the ending is changed into *æ* in the genitive; the accusative takes the ending *am* in the singular and *as* in the plural. As far as the nouns concerned in expressing medicinal terms, they end in *us* or *um* in the second declension in the nominative case and *i* in the genitive, as illustrated in the above prescription. However, there are few exceptions to this rule. These exceptions end in *on* in the nominative and *i* in the genitive; as for example "erythroxylon," "hematoxylon" and "toxicodendron."

There is a greater variety of endings in dealing with nouns of the third declension. The great majority, however, end in the nominative singular in one of the following letters: o, l, n, r, s, and x. We give a few of the nouns as follows for sake of illustration:

NOMINATIVE.	GENITIVE.
Mucilago.	Mucilaginis.
Alcohol.	Alcoholis.
Albumin.	Albuminis.
Ether.	Etheris.
Salicylas.	Salicylatis.
Rumex.	Rumicis.

(To be continued.)

Treatment of Glaucoma.

The following is recommended by *Merck's Archives* in the treatment of glaucoma:

℞.	Eserinæ salicylatis	gr. 1-6	01
	Pilocarpinæ hydrochlor	gr. iii	20
	Cocainæ hydrochlor.	gr. iss	09
	Aquæ destil. q. s. ad	℥ii	64

M. Sig.: One or two drops into the eyes at bedtime.

Treatment of Diabetes.

It is stated by van Noorden, in *Wiener Klin. Wochenschrift*, that the tolerance of the system for carbohydrates in diabetes is very much increased by the use of salicylic acid. This is unusually beneficial in those who tolerate from 100 to 150 grams of bread.

Chloretone in Surgery.

The administration of chloretone before ether or chloroform anesthesia with a view of preventing nausea and vomiting during and after surgical operations, is recommended by Dr. Hirschman, in the *Ther. Gazette*. He gives doses of 10 grains to women and to boys under 16 years of age, and 15 grains to men. This is given one-half hour before commencing the anesthetic. He gives it in powder form, dry on the tongue, washing it down with water.

Patients treated in this way, the writer states, have but little or no stage of excitement; about one-third or one-half less of the anesthetic is required only, and the patient is less apt to come out of the anesthesia suddenly during the operation should the administration of the anesthetic be relaxed. He makes the statements based upon a comparative study of sixty cases, half of whom received chloretone and the other half none.

Treatment of Gastralgia.

Gastralgia produces symptoms which may be mistaken for other and graver conditions, such as carcinoma of the stomach, gallstones, appendicitis, chronic mucous gastritis, etc. If these can be eliminated in the diagnosis Melbec, as noted in *N. Y. Med Jour.*, recommends the following outline of treatment:

When an attack is threatening take alternately in tablespoonful doses the following mixtures:

℞.	Cocainæ hydrochlor.	gr. ivss	25
	Tinct. illicii	m. xv	1
	Aq. aurantii flor	℥iii	96

M. Sig.: One tablespoonful every half hour, alternating with the following:

℞.	Aq. chloroformi (saturat.)	℥ii	64
	Syr. belladonnæ		
	Aq. menth. pip. āā	℥i	32

M. Sig.: One tablespoonful every half hour.

If the pain persists and is very severe, give a hypodermic injection of the following, repeated within a few minutes if necessary:

℞.	Cocainæ hydrochlor.	gr. ¾	045
	Morphinæ hydrochlor.	gr. iss	09
	Aq. destil.	3iiss	10

M. Sig.: Eight minims hypodermically and repeat in fifteen minutes.

In the intervals between the attack seek the cause, chlorosis, neurasthenia, etc. Give daily alcohol baths and follow with rubbing with a hair glove. Take every other day the following mixture:

℞.	Strontii bromidi	℥v	20
	Syr. hyoscyami	℥ii	64
	Syr. aurantii	℥ii	64
	Aq. destil.	℥v	160

M. Sig.: One tablespoonful in water every other day.

Counter-irritation should be made over the epigastric region by means of the actual cautery. This should be applied about once a week.

Salol in Smallpox.

Dr. C. Begg, in a paper read before the Medical Society in Edinburgh, states that beneficial effects are produced by salol, inasmuch as, 1, it tends to abort the pustular stage; 2, it tends to diminish the irritability of the patient, and 3, it prevents the giving off of an unpleasant odor. As soon as the vesicular stage is completed Dr. Begg applies the following locally:

℞.	Ol. eucalypti	m. v	30
	Calaminæ	3iii	12
	Zinci oxidi	℥ss	16
	Glycerini	℥ss	16
	Aq. calcis q. s. ad	Oi	512

M. Sig.: Apply gently with a camel's hair brush.

In prescribing salol he usually gives it in doses of 15 grains three times a day, beginning with the appearance of the first eruption and continuing it until the stage of desquamation is finished.

Methyl Blue in Smallpox.

Prof. Matoni, in *Arte Medica*, states that he has obtained very satisfactory results from the use of methyl blue in the different stages of smallpox. In the pustular stage he administers it in divided doses amounting to 6 or 8 grains daily. In this stage his results have been especially satisfactory.

Removal of Warts.

It has been recommended that the removal of warts be done by means of electrolysis, first injecting them with a 4 per cent. solution of sodium chlorid. This, it is claimed, promotes electrolytic action by cutting down the resistance in the

tissues, at the same time favoring the destruction of tissue by the formation of caustic soda.

Medicolegal.

Aggravation of Injury by Improper Treatment.—The Appellate Court of Illinois, First District, holds, in Chicago City Railway Company vs. Cooney, that if the negligence of the company was the direct cause of the injury in question, and it was simply aggravated by some improper treatment by medical attendants through no fault of the injured party or lack of care on her part in selecting such attendants, then the mere fact of such aggravation of the injury would not preclude a recovery for the injury in the suit against the company.

Surgeon Prevented from Reducing Dislocation.—The Appellate Court of Illinois, Third District, holds, on the second appearance before it of Littlejohn vs. Arbogast, that if the surgeon charged with malpractice was prevented from reducing the dislocation of his patient's hip by the refusal of the latter to submit to an operation, he could not be held liable for damages resulting therefrom. It is the duty of a patient, it holds, to submit to the necessary treatment prescribed by his physician or surgeon. If the patient is delirious and can not be made to understand the necessity of the treatment proposed, the physician or surgeon may co-operate with the patient's immediate family and resort to reasonable force. If the patient is in that condition and the members of his family having him in charge refuse to allow the proposed treatment, then the physician or surgeon would not be required to use force. Surely, he should not be held liable for injury to limb or health resulting from a failure to use the proposed treatment.

Nature and Limitations of Physician's Claim.—The Supreme Court of Alabama says, in Morrisett vs. Wood, that the nature of the demand of a physician for medical services rendered without a special contract therefor is simply an implied promise to pay what such services are reasonably worth, and the proper action for their recovery is what is called assumpsit for such compensation as may be shown by the evidence that the physician rendering the services ought to receive. This demand, in the absence of a special contract as to what shall be paid, is an open account. In an action for its recovery it is difficult to escape the conclusion that an account is not the foundation of the suit. Such a demand is subject to the bar of the statute of limitations of Alabama of three years, as provided by statute against open or unliquidated accounts. This defense of the bar provided by the statute can be made because the basis or foundation of the claim is an account which has not been stated. And the court says that it can draw no distinction between the word "account" as used in the statute of limitations of three years and as employed in the section as to a bill of particulars, which provides that at any time previous to the trial, upon notice to the attorney of the party suing, the one sued may have a list of the items composing it, when an account is the foundation of the suit. It means the same in both sections. Therefore, the court holds that, in this case, which was brought by a physician against an executor of an estate to recover for medical services rendered the decedent during his last illness, the contention was untenable that an account was not the foundation of his claims or demands, one of which was for such services, and the other for work and labor done for the decedent at his request. So it holds that the executor was entitled to demand a bill of particulars, or list of items composing the account. Then, this having been furnished, but the witnesses called to substantiate it not being able to verify any of the dates, the court holds that it was error to allow the physician to prove the value of his services by a hypothetical question based on the assumption that he had treated the decedent as often as a certain number of times a month between certain dates, as also that it was error to instruct the jury that under the claim for work and labor they were not limited to proof of the items given in the bill of particulars. The proofs, it holds, should have been limited to the bill of particulars as to the services rendered and the value of the particular items of services when shown.

Provision of Law as to Examination Upheld.—The Supreme Court of Wisconsin says that the gravamen of the relator's complaint, in the case of State ex rel. Kellogg vs. Currans and others, was that he was refused a license to practice medicine in Wisconsin except upon the condition of passing an examination before a medical board created therefor, and paying a fee which must be considered as but compensation for the service of holding that examination. It appears that he matriculated in 1897, and took one course of six months at a reputable medical college of Wisconsin, and then completed his course at a reputable medical college located in Chicago. As the law was in Wisconsin until its amendment in 1901, he would have been entitled to a license to commence practice either on the diploma he obtained, or upon passing examination. But the amendment makes both diploma and examination prerequisite to license to beginners, with proviso that "any student who is now matriculated in any medical college of this state which requires [specified courses of study], shall, on presentation of his diploma from such medical college and on payment of the fees specified in this act, be admitted to practice without further examination." "The fee for such examination shall be fixed by the board, but shall not exceed $10, and $5 additional for the certificate if issued." He strenuously attacked the validity of this statute. But the Supreme Court of Wisconsin does not think that it infringes either that provision of the federal constitution which provides that the citizens of each state shall be entitled to all the privileges and immunities of citizens in the several states, or the one which prohibits any state to make or enforce any law which shall abridge the privileges or immunities of citizens of the United States. Nor does it consider that it violates the provision that no state "shall deprive any person of life, liberty, or property, without due process of law, nor deny to any person within its jurisdiction the equal protection of the laws." It declares that there can be no doubt that it is within the proper power of the legislature to provide that some people may and some may not practice medicine, provided that the characteristics and conditions distinguishing the former class from the latter are of a kind tending to make their exercise of that profession more beneficial or less perilous to the community than the class excluded. The reasonableness of a requirement that one establish his educational qualifications by submitting to an examination, it continues, is one which pertains directly to one of the characteristics which should distinguish those permitted to practice medicine from those not permitted. As to the statute making a class of those who should obtain the education afforded by the then existing medical colleges in the state of a specified standard, it asks: May not the legislature of 1901, upon evidence or investigation, have been convinced that such colleges could be trusted to give education to their graduates to make them safe practitioners, while they could not be so satisfied as to all colleges outside the state? The character of the men conducting the former class, the opportunity and right of the legislature to control and to prevent deterioration, the special applicability of the instruction to the diseases or phases of diseases characteristic of Wisconsin—might not considerations such as these have weight with honest and reasonable minds, and lead them to deem safer the graduates of such institutions, as a class, than those of all other colleges, as to the great majority of which the legislature could neither gain knowledge nor exercise any control? Wherefore, the court holds the act within the police power of the state. And it adds, in closing its opinion: "The fact, if it were a fact, that less educational requirements are demanded from osteopaths as preliminary to an examination by the board, in no wise affects the relator, whose qualifications for admission are, as he alleges in his relation, all conceded, except the passing of the examination. The question whether the requirement of a diploma is an unconstitutional one, as discriminating against those who by some other method of study have acquired equal education, is not open to the relator, who confessedly has his

diploma. We can not set aside the acts of the legislature at the suit of one who, suffering no wrong himself, merely assumes to champion the wrongs of others."

AMERICAN.

1. **Apoplexy.**—Accepting under this head the symptom commonly known as "stroke," Diller holds that its occurrence without the production of either paralysis or loss of consciousness is far more common than text-books would lead one to believe. The recognition of such conditions is of great importance. It often happens that only one of the two symptoms may be present, and he reports several cases that indicate this fact. One was apoplexy without either paralysis or loss of consciousness, one producing hemiplegia without loss of consciousness, one producing loss of consciousness and mental disturbance but no paralysis, etc.; also complicated cases and cases of loss of consciousness with hemiplegia due to other causes than apoplexy or without apparent cause. He remarks that it may be trite to say that apoplexy is only a symptom not a disease in itself. Hemorrhage or thrombosis can occur only when blood vessels are diseased and embolism can only follow the entrance of a foreign body into the blood stream The rise of blood pressure is the most frequent determining cause of apoplexy and in this we have our most significant hint of prophylactic treatment.

2. **The Etiology of Apoplexy.**—Walker remarks on one of the cases noted by Dillon and insists on the importance of auto intoxication and the influence of heredity in producing vascular degeneration.

3. **The Klebs-Loeffler Bacillus.**—The summary and conclusions of Rupp's article are in substance as follows: 1. Clinically there are two kinds of diphtheria as regards the Klebs-Loeffler bacillus, those where the bacilli are present and those where they are absent. Both forms have the same clinical history and complications and sequelæ, von Behring to the contrary 2. The character or quality of the Klebs-Loeffler bacillus in any case of diphtheria does not affect its prognosis. 3. Klebs-Loeffler bacillary diphtheria may be so mild as to simulate tonsillitis, and yet the most virulent bacilli be present. 4. The virulent bacilli may be present in the throats of healthy people, doing no harm either to themselves or others. 5. The Klebs-Loeffler bacilli are found associated with other bacilli in other diseases than diphtheria, but fail to exert any appreciable influence on these diseases. 6. Klebs-Loeffler bacilli vary much in size and shape from the regular and artificially determined type and the amount and quality of their toxicity is not bound in any special or definite way to fit any particular typical or atypical form, if the most recent bacteriologic utter-

ances on the subject be true. 7. The virulency of disease-promoting qualities of the Klebs-Loeffler bacillus can be determined only by experimental inoculation tests. The microscope can only differentiate their forms. Any opinion based on microscopic investigation alone is largely guess-work. 8. The ubiquity of the Klebs-Loeffler bacilli and their irregular and varying forms, besides the inconstancy of their toxic qualities in no way correlates with the clinical phenomena, making it impossible to grant them any primary specific etiological importance in the pathogenesis of clinical diphtherias. 9. The "necessary influences" and the "favoring conditions," besides other factors unknown to us, enfold within themselves the secret of the real causes—not cause only—of clinical diphtherias. 10. The assumed etiologic and pathologic supremacy of the Klebs-Loeffler bacillus is largely, if not altogether, a synthetic demonstration, and although this is not altogether "a bridge of fancies," enthusiastic laboratory workers and their unquestioning followers are traveling over it unhampered by the odious uncertainties and difficulties that have been presented in this paper.

5. **Nitrous Oxid and Ether Narcosis.**—Carter advocates the utility of nitrous oxid and ether narcosis as opposed to the use of ether and chloroform alone. He thinks the method especially valuable in neurotic patients and children and in valvular disease of the heart it can be used with almost perfect safety. Old people take it well, but special care should be exerted and its use avoided in all cases of arterial degeneration. In pulmonary diseases, provided the heart is not affected, he would advise the use of chloroform in preference to gas and ether, though mild cases do not contra-indicate the use of nitrous oxid. The only disadvantage of the method is that it requires somewhat complicated and expensive apparatus and expert skill to administer it, but its general adoption would necessarily lead to the systematic instruction in anesthetics, and would make expert anesthetists.

6. **Cutaneous Epitheliomata.**—The following are the conclusions of Allen's article: 1. Cutaneous cancer can be traced in almost all instances to preceding local irritation. 2. While other causes may be operative, it is not unreasonable to assume that infection may be one source of irritation occasioning cancer. 3. Benign epitheliomatous proliferations of infectious nature transmitted by contagion lend weight to this view. 4. Cancer is curable, but the disease may be allowed to progress until the patient no longer is. 5. No treatment short of the most radical measures should be tolerated. 6. In the application of caustic pastes and subsequent cauterizing dressings we possess a method not alone radical, but one which is in many conditions preferable to the knife. 7. The earlier treatment can be applied, the less likelihood is there of recurrence or of subsequent outbreaks in other parts due to cancerous tissue which has been left behind. 8. The *x*-ray as a means of treatment bids fair to prove quite as effective as caustic applications.

7.—See abstract in THE JOURNAL, xxxvi, p. 1652.

8. **The Lane Lectures.**—In this ninth lecture Morris reviews feigned eruptions, erythema of various types, keratodes, multiforme, herpetiforme, pemphigus, erythema nodosum, lupus erythematosus, rosacea, lichen, lichen neuroticus, skin neurosis and mental disturbance, zona, and eczema. He follows Head's opinion that zona, occurring idiopathically without obvious cause, is an acute specific disease of the nervous system analogous to anterior poliomyelitis. As regards eczema he does not support the parasitic theory, considering that it is not proven, though secondary infection is undoubted. In a large proportion of cases he thinks it is produced by disordered innervation of the skin and that the diminished resistance thus caused opens the way to invasion of the micro-organism.

9. **Muscular Atony in Uterine Displacements.**—The importance of this element in uterine displacements is insisted upon by Coe, who offers the following deductions for discussion: 1. Muscular atony is an important factor in the causation of uterine displacements, either alone or associated with the usual factors, overweight of the uterus and weakening of its ligaments and the pelvic floor. 2. Mere restoration of the organ to its normal position with regard to the axes of the pelvis is not sufficient to cause permanent relief of symptoms, provided additional support is not afforded by firm pelvic and abdominal muscles. 3. The prognosis as to the cure of malpositions by operations is influenced by the general muscular tone of the individual. 4. Hence it should be the aim of the physician to endeavor to restore such a healthy condition of the muscles, either before or after operation, by appropriate treatment—baths, massage, electricity, gymnastic movements, out-of-door exercise, tonics, and such regulation of the patient's dress and mode of life as seem best fitted to the individual case. In short, the work of the physician often begins where that of the surgeon ends, if the result is to be complete and permanent.

10. **Devitalized-Air Toxemia.**—Denison insists on the importance of the proper condition of the air, referring to Richardson's experiments as showing that oxygen may be deficient in quality, irrespective of quantity, and hypothetically explaining it by some atomic changes due to electrical disturbance. The toxin which he specially considers as having influence on the development of phthisis is due to stagnant unventilated air existing in the lungs themselves. The unrenewed pulmonary air is simply a tenfold intensification of devitalized air of the environment in which the consumptive lives. He criticises the too exclusive bacteriologic theory of consumption, claiming that it never has been and never will be shown that bacteria are the sole cause of diseases classed as tuberculous, for other causes are entitled to quite as much consideration. The nonconformity to healthful environment is the greatest scourge of the human race.

12. **The Philippines.**—The sanitary conditions in the Philippines are described by Chamberlain, who thinks that it is, for a tropical country, a healthy one. The water supply, however, is usually bad and should be looked after. Dysenteric troubles prevail. The sanitation of dwellings has been unduly neglected there by the natives in the past. Malaria is less prevalent than in Cuba, and he thinks that many cases so diagnosed are really a special fever, which may possibly be Malta fever. Venereal disease is not so prevalent or so serious as was expected. Tuberculosis, while not common, usually takes a bad course, and if the patients remain there, they are soon beyond hope. Skin diseases are very common. The natives live chiefly on rice, but this is simply a matter of necessity rather than of desire. He thinks the army ration does not need any extensive modifications. If any alteration is desirable it is the addition of sugar, which the soldiers seem to crave. The greatest needs there are permanent barracks, general vaccination, segregation of lepers, instruction as to sanitation and study of tropical diseases.

13. **Army System of Personal Identification.**—The army system of personal identification is described by Alden, which seems to be a modified Bertillon plan, and its advantages are shown.

14. **Medicolegal Diplomas.**—The use of the medicolegal diploma and the selection of experts by special qualification, is advocated by Johnston, who describes the standard selected by the Faculty of the McGill University for giving this diploma and believe that when it becomes recognized as a qualification for expert work the advantage will be obvious.

17. **Trional Fatalities.**—Church has collected from the literature a number of cases of fatalities from the use of trional and sulphonal and adds a case of his own with autopsy. He gives special warning that abdominal distress and urinary derangements, including hematoporphyrinuria, indicate trional poisoning of a very grave character, and that the drug, even in so-called safe doses, may give rise to serious and even fatal toxic conditions.

18.—This article has appeared elsewhere. See abstract in THE JOURNAL of October 19, ¶85, p. 1066.

19. **Internal Lesions from Burns.**—From a series of 13 cases, McCrae has been led to the following conclusions: 1. The entire pathologic picture presents great similarity to the

conditions found in the diseases characterized by the presence of toxins of bacterial origin in the blood. 2. Damage to the lymphatic tissue is a constant feature, but is not necessarily focal, some cases presenting only diffuse degeneration. The cases which live but a few hours after infliction seem more likely to present a focal condition than those which live a longer time, as the condition which he interprets as proliferation and phagocytosis is one which may rapidly disappear. 3. The focal lesions are not a true necrosis, but rather a proliferation of the endothelial cells of the reticulum and the capillaries, and a phagocytosis by the leukocytes and endothelial cells, to which latter is due the fragmented, disintegrated appearance which suggests a true necrosis.

20. **Bacteriology of Otitis Media.**—This article deals only with the bacteriology of disease of the middle ear. Funke thinks that otitis media may occur in the absence of bacteria, or rather that the literature contains cases that seem to indicate this. The route of entry of infection may be through the blood, through the Eustachian tube, through the tympanic membrane as shown by Moos, through the petrosquamous fissure and by still other routes, but the most important is by the Eustachian passage. The bacteria found are the pneumococcus, streptococcus, and staphylococcus, Friedländer's bacillus, typhoid bacillus, bacillus diphtheriæ, tubercle bacillus, and bacillus pyocyaneus, as well as some miscellaneous forms which have been noted in isolated cases. He concludes with quite an extensive bibliography of the subject.

23. **Uterine Cancer.**—A review of the literature leads Noble to the following conclusions as to uterine lesions: 1. The majority of cases are too far advanced when first seen to hope for radical cure. 2. The percentage of cases of cancer of the cervix remaining free from recurrence at the end of five years under vaginal hysterectomy is variously given, but it may be claimed confidentially that at least 10 per cent. do so, and may be considered cured. 3. The results of hysterectomy, whether vaginal or abdominal, for carcinoma of the corpus are much more satisfactory. Statistics seem to show that about 75 per cent. of the cases are permanently cured, hence a good prognosis may be confidently given for abdominal operations. 4. The abdominal radical hysterectomy for uterine cancer involving the pelvic glands and the parametria along with the uterus is still upon trial. Its primary mortality is probably double that of vaginal hysterectomy and permanent conclusions as to the results are not yet possible. The most encouraging report of the operation is that of Wertheim, that after two and one-half years' experience he has had no recurrence. Noble's experience with cancer has not been satisfactory. He thinks his operative cases have been less than the average.

25. **Surgery of the Lungs.**—Eisendrath reviews the history and conditions of pulmonary surgery and offers the following conclusions: 1. Both acute and pulmonary abscess and gangrene following pneumonia may develop immediately, and chronic and simple putrid abscesses, with or without bronchiectases, are more remote sequelæ of both croupous and influenzal pneumonia, especially the latter. 2. The most valuable points in the history are the etiology; the sudden expectoration, after an apparent crisis, of pure non-odorous pus in the simple abscess cases, or of fetid pus in the gangrenous variety. In the chronic cases there is usually a history of a pneumonia having preceded the condition at some considerable time previously, followed by expectoration of large quantities of pus, with exacerbations of fever, accompanied by emaciation and frequently clubbed fingers, etc. 9. Signs of cavity are seldom present. The moist râles, especially of large metallic character, are the most reliable physical signs. The character of the sputum is also of great value, whether purulent or fetid. Elastic fibers are more frequently found in gangrene than in abscess, being comparatively rare in the latter. 4. The *x*-ray is only of confirmatory value, as it shows chiefly thickened areas of lung, and should not be absolutely relied upon. When it shows a shadow at the same point where the physical signs are present, it is of value. 5. The prognosis of abscess and gangrene following pneumonia, medically treated, is very favorable. One of the greatest difficulties is the exact localization of the focus. His statistics show a marked increase in the percentage of recoveries within the last five years. The prognosis of chronic cases is not so favorable. The walls of the cavity are often rigid and free communication of a bronchus with these cavities is also a great hindrance. The statistics are improving.

26. **Pneumonia.**—Hall's analysis of 70 cases is quite thorough and certain special points are noted. He does not think the increasing mortality of pneumonia means that it has become more malignant. The decreasing death rate from tuberculosis, diphtheria, typhoid and other diseases leaves more people to grow old. Pneumonia is a disease of advancing age. He thinks it entirely probable that its mortality will continue to increase, for it will be a final infection of those escaping death from other causes. Of the remedial measures he has seen benefit from judicious bleeding and great relief from ice-packs in pyrexia. Insomnia requires opiates rather than depressing hypnotics and the free use of strychnia in recent years is a great gain. Cardiac depressants are not advised by him. Liquor ammonii acetatis or sweet spirits of nitre seem to be equally good. Digitalis has been given frequently in cases of heart weakness, and alcohol where needed. He thinks the use of oxygen has been of value in some cases. His opinion as to serum therapy is not too favorable.

27. **Hospital Abuses.**—The special abuses noticed by Hillis are the promiscuous mixing of paupers, pay patients and criminals in hospital wards and the lack of distinction between pay and non-pay patients generally which favors imposition, the propriety of charity patients paying for their treatment by being used for medical instruction, the need of better training of internes in the preparation for hospital service and the payment of the hospital staff. No class of men should be obliged to work for nothing for the community when others do not.

28. **Influenza.**—Anders has analyzed the climatic conditions of influenzal epidemics and finds that the disorder seems to depend more or less on extremes of cloudiness during the season. La grippe seems to like darkness better than light, but he says it is not inferable from his observations that there is the positive and direct relation between the absence of sunshine and the prevalence of la grippe that Ruhemann would have us believe.

32. **Typhoid Fever.**—Taylor pleads for treating typhoid by assisting Nature, favoring assimulation, minimizing waste, deflecting the patient's mind from his business, reorganizing the organism and allowing each organ to do its work to its best advantage. He says the best rule is "if you don't know just what to give don't give anything." There is already inflammation of the bowels, and it is unsurgical to use purgatives like calomel. If nausea exist, give the stomach rest until it can digest food; feed three times a day and give just such food as can be perfectly digested, beef tea and beefsteak pulp moderately heated, powdered crackers, raw eggs. Never allow the patient to eat anything that requires mastication, but always have food prepared so that it needs only to be mixed with saliva. The milk diet he condemns, as also the use of alcoholics. Avoid disturbing the patient during sleep. Allow the patient to drink all the water that is desired. Keep the mouth clean. For restlessness, bromids are effective and leave no bad result. If there is much decomposition in the intestine, he uses saline cathartics and then tincture of iodin and carbolic acid in small doses until they are contra-indicated. Colon irrigation is employed three times a day with warm water. If there is catarrh a little extract of pine and Dr. Mathews' prescription of almond oil, bismuth and iodoform, at night. Two typical causes are reported, and he says in the treatment remember the stomach first, the colon next.

33. **Urinary Toxicity in Pregnancy.**—Stewart details experiments which he has made to determine the toxicity of urine during pregnancy, and while the general result is somewhat undetermined, he leaves the impression that while it has been heretofore attributed to poisons generated in the

human body, it is more often due to micro-organisms. In his own experience, 75 per cent. of deaths could not be attributed to any other cause than bacteria due to infection of urine during catheterization or subsequent manipulation.

35. **Dermoid Cyst of Testicle.**—Morris reports a case of true dermoid of the testicle, containing hair and two teeth. The condition seemed to be congenital as it was probably noted the second day after birth.

36. **Gunshot Wounds of the Pregnant Uterus.**—Gellhorn continues the report of cases from the literature and gives an analysis of the symptoms. From his observation he thinks that in every case of gunshot wound of the pregnant uterus, Cesarean section should be performed at once. The Porro operation is preferable on account of possible infection.

37.—This article has appeared elsewhere. See THE JOURNAL of September 28, p. 869.

38.—Ibid.

39.—Ibid.

40. **Essential of Toxemic Dropsy.**—The disease described by Herringham is a condition in which there is dropsy in the legs, sometimes in the arms and face, exactly resembling renal dropsy, but with no albumin in the urine and no constant lesions. The disease closely resembles nephritis in its causation by cold and scarlatina, but can not be explained by the ordinary theories. He is inclined to think that it is due to some toxic poisoning, such, for instance, as that of scarlatina, which may in some cases produce anasarca without inflammatory disease of the kidney and in other cases produce both anasarca and kidney disease. The treatment that has been employed in these cases has been wet packs, hot-water baths, hot-air baths, and iron for the anemia. He suggests the use of syrup of iodid of iron and arsenic, and also endeavors to stimulate the kidneys by milk and digitalis.

41. **Tendon Grafting.**—White refers to the unequal results obtained in tendon grafting, but reports a case showing the advantages. He thinks that the method is a valuable addition to our means of treating a class of cases which, previous to its adoption, were alike objects of pity and reproach to the medical art.

50.—See abstract in THE JOURNAL of October 5, p. 932.

51. **Feigned Impairment of Vision.**—The simple test here used by Snydacker is based on the common belief of ignorant people that they can look at an object with both eyes open and use only one eye. The physical defect here claimed was in the right eye. The left was normal in its visual field, while the right was somewhat contracted. The patient was seated at the perimeter, his right eye gazing at the test object, his left behind the screen, and while thus using only his right eye, the screen was quietly removed from the left and he still claimed to see the same contracted field which the observation of the right eye had previously disclosed. Malingering was, therefore, revealed.

52. **Prostatic Hypertrophy.**—Schmidt describes the various forms of prostatic obstruction, the collar-shaped, hypertrophic enlargement of individual lobes, pedunculated lobes and the formation of large tumors growing into the cavity of the bladder. The methods of diagnosis are given.

54. **Inflammatory Affections of the Nails.**—The various conditions that may affect the nails are noticed by Pollitzer, who believes that the majority of onychias are principally due to staphylococcus aureus. Onychia maligna is a special form rarely seen, which is at least due to bacillus tuberculosis in some cases, while Jonathan Hutchinson holds that it is generally due to syphilis. The most common of all the acute inflammatory conditions is the ingrowing toe-nail. It is due, as a rule, to ill-fitting shoes. The age period of its occurrence, between 15 and 20, and the common association of hallux valgus support this view. Before leaving idiopathic diseases he mentions confectioners' onychia, which is due to the practice of putting their fingers into hot syrup fruits. Next he notices diseases in which the nail inflammation forms a part of an inflammatory dermatosis; among them hyperkeratosis sub ungualis, a rare condition regarded by von Hebra as localized eczema. Eczema of the nails is a protean condition; variability is its special characteristic. Psoriasis may also affect the nails and occurs in two forms, early and late. The early form consists in the development of minute hyperemic spots seen in the proximal portion of the lunula underneath the cuticle, followed by punctate softening and desquamation and the nails finally come to have an appearance of a thimble. In the severer forms of psoriasis the nail-plate is raised up by a dry crumbly mass of scales and a special feature is the occurrence of a sharply marked transverse depression which extends as a "punched-out" groove several millimeters broad across the nail. Above and below this groove the nail-plate may appear comparatively normal. Changes in the nails may occur in pityriasis or pemphigus. Syphilitic affections are very important: chancre of the terminal phalanx is not infrequent. As manifestations of a general syphilitic infection, two groups of nail affections may be described, those which are dry and those which are moist. The first form has occurred as early as eight months after the infection, but most cases occur from two to ten years later. While essentially chronic, it generally yields to anti-luetic treatment. Of the moist forms of nail-syphilis, paronychia ulcerosa syphilitica is the most common, generally occurring during the greatest activity of the general infection. The nail-plates may fall off and their place be filled by ulcerations. The condition is more rarely seen now-a-days owing to the general recognition of syphilis and the improvement in its treatment.

55. **Trophic Affections of the Nails.**—Zeisler describes in this article the transverse furrows or grooves which follow fevers and are due to temporary disturbance or arrest of their growth in the matrix and a somewhat rarer central excavation or depression of the plate due probably to processes of shrinking in the nail bed and described as koilonychia. Alopecia ungualis consists in the total falling off of one or more nails without notable cause and without pain or inflammation: this, he thinks, is due to some unexplained trophic disorder. It has been known to follow severe shock or on exposure to the Roentgen rays. Nail atrophy is another condition first observed in connection with other diseases, and sometimes with disturbed nutrition and peripheral nerve lesions. One form in which it shows itself is brittleness, another is a tendency to longitudinal splitting. He also mentions the leuconychia or white spots under the nails, which may be due to slight traumatism, but these often can not be traced. The chief hypertrophic condition of the nails is a transformation into claw like appendages. He mentions a case seen by him in which he attributed this to a deep-seated trophic disturbance. In conclusion he mentions the connection with general diseases, frequent inflammation of the nails after nerve lesions and in Raynaud's disease or in syringomyelia.

56. **Parasitic Diseases of the Nails.**—These are chiefly limited to onychomycosis, the animal parasitic affections requiring barely more than mention. The symptoms are described, also the varieties of favus, trichophytosis, and their etiology. Auto-infection seems to be the principal cause in these cases. The various points of diagnosis are pointed out.

57. **Treatment of Nail Disease.**—Hardaway insists on the importance of antisepsis and limitation of the care of the nails to the free borders. In eczema and psoriasis, arsenic internally is advisable and lactophosphate of lime and sulphur are also of considerable value. Th local treatment consists mainly in the use of the preparations of tar, salicylic acid and chrysarobin combinations. We should pay attention to paronychial conditions in onychia and eczema. Syphilis of the nails, of course, is managed by specific treatment. Onychomycosis is rare; after the proper scraping and paring, the usual parasiticides may be employed. Several prescriptions are given. In ordinary onychia, division or evulsion of the nail is generally demanded and gives relief to pain and tension. In most instances strict cleanliness and the use of some antiseptic lotion is all that is necessary in the way of after-treatment. Where there is a suspicion of tubercular granulations, Shield

insists upon the free use of the curette followed by the application of pure carbolic acid. In onychia maligna, as seen in strumous children, tonics and nutritious food should be made an essential part of the treatment. For hypertrophies and atrophies no precise rule can be laid down. Surgical procedures are occasionally demanded. Ingrowing toe-nail is mainly surgical in its treatment, but often relief may be had by inserting lint or tinfoil under the niche of the nail in mild cases.

58. **Internal Urethrotomy.**—Lydston suggests as a possible cause for failure, that more importance should be attributed to idiosyncrasies in these cases. The possible constitutional tendency to fibrous hypertrophic tissue growth should be taken as one of the best explanations.

71. **Epidemic of Noma.**—Blumer and MacFarlane report the facts of an epidemic of noma that occurred at the Albany Orphan Asylum, sixteen cases altogether, and discuss them in the light of the literature. As a result they conclude that noma, while originating in all probability as a simple infection, is always in its later stages a mixed one. While it is probably not always due to the same organism, it is more frequently caused by long thread-like organisms of the leptothrix type that do not grow on ordinary culture media. Krahn's assumption that it is due to mouth organisms is negatived by finding similar organisms in the noma of the genitalia.

72. **Raynaud's Disease.**—Beck reports two cases and illustrates them with skiagraphs showing that the tissue changes in Raynaud's disease are not confined to the soft tissues, but also affect the bones. In the cases reported there was an atrophy of the upper ends of the third phalanges of the hand, and osseous proliferation of the upper end of all the second phalanges.

73.—See abstract in THE JOURNAL, XXXVI, p. 1339.

74. **Osteitis Deformans.**—A case is very fully reported by the authors and the literature of the condition discussed. From a clinical standpoint he concludes that: 1. Sixty-six true cases are found in the literature besides the one here reported. 2. Osteitis deformans is a distinct disease of obscure etiology possibly allied to, though not identical with osteomalacia, fragilitas ossium and acromegaly. 3. The disease is especially one of adult life, though it has been observed as early as 21 years. The largest percentage occurs in males; in a small proportion traumatism seems to play a part in the causation. There is little evidence of any family tendency to the disease, though there are a few examples in the literature. 4. There is a striking general resemblance in the subjects in their general characteristics, the most noteworthy features of which are enlargement and forward projection of the head, dorsal cervical kyphosis, prominence of the clavicles, spreading of the base of the thorax, diamond-shaped abdomen, crossed by a deep sulcus, the relative increase in the width of the hips, and the outward and forward bowing of the legs. 5. The bones most frequently affected are those of the clavicle, tibia and femur. There is a curious preponderance of cases involving chiefly those of the left side, though in some cases it has been crossed, the lower extremities on one side, and the upper on the other being most affected. 6. The association with malignant disease, while present in the case reported, does not seem to be so frequent as usually stated. From a pathologic standpoint the following conclusions are offered: 1. Osteitis deformans is a disease affecting the skull, vertebræ and certain of the long bones. Its essential characteristics are: (*a*) Absorption of compact substance, causing enlargement and confluence of the Haversian canals. (*b*) Formation of new bone which runs diffusely through the affected and the adjacent healthy portions, and which remains uncalcified and is in turn reabsorbed. (*c*) Conversion of the medullary substance into a vascular connective tissue containing fat cells, giant cells and leucocytes. In a small proportion of reported cases the cysts fill with gelatinous matter and giant-celled sarcomas occur in the medulla. (*d*) As a consequence of these processes the original relations of compact substance in the medulla are destroyed, the bones become thickened and asymmetrical, but since the new bone tissue remains uncalcified its elasticity permits of great deformity of the long bones from the weight of the body, and fractures do not occur. 2. The whole picture of osteitis deformans from its pathologic aspect is so characteristic that it must be considered a distinct disease of easy pathologic diagnosis. 3. The etiology of this is as obscure as when first described. Some predisposing tendency, probably trophic, must be assumed and the exciting cause must be mechanical; in the skull, extremes of heat and cold, and in the vertebræ and long bones the ordinary traumata to which these bones are exposed. Lesions of the nervous system are inconstant and rare and probably not a causal factor.

75. **Asymmetry of the Nasal Cavities.**—The following propositions are offered by Coolidge as giving the main points of interest in regard to this condition: "1. In cases of deviation of the septum, the common asymmetries of the other intranasal structures should be classed as physiological compensatory changes. 2. As a rule, these changes in the turbinated bodies and ethmoid bone are not due to increase or diminution of the air current. Neither is the deflection of the septum often secondary to asymmetrical turbinates. 3. Whatever may be the mechanism which underlies this adjustment, the ethmoid and the turbinated bones are especially endowed with nutritive adaptability, and in consequence are able to minimize the disturbance which a deflecting septum would produce. Slight deflections are often rendered entirely innocuous, more extensive ones partially so. 4. The entrance into the nasal cavities proper can not share in this readjustment, and here a deflection of the cartilage of the septum soon becomes obstructive."

77. **Typhoid Cholecystitis.**—Pratt reports cases of cholecystitis and cholelithiasis associated with the presence of typhoid bacilli in the gall-bladder, and points out the probabilities of the agency of this germ in the production of cholelithiasis.

79. **Infantile Bone Lesions.**—Two cases are reported by Taylor showing the difficulties in the diagnosis of bone lesions of children. In the first there was a diagnosis of scurvy with a suspicion of tuberculous osteomyelitis, the second one had the symptoms and picture of Pott's disease; on the abscess being evacuated it showed the staphylococcus aureus. He suggests making the blood examination a part of the routine record as well as that of the urine.

81. **Tuberculosis of the Cervix.**—Beyea reports a case of tubercular infection of the portio vaginalis and cervix uteri and discusses the condition from the literature. He has been able to collect 69 cases including his own, which he analyzes. He points out the peculiarities. The treatment should be operative, as a rule, excepting where there is extensive disseminated tuberculosis.

82. **Ophthalmoplegia.**—Adt points out the difficulties of certain theories of locating lesions affecting the ocular muscles, more particularly those involving the nucleus of the third nerve and those involving the root fibers of this nerve in the tegmentum. He concludes that our knowledge of decussation of the root fibers of the ocular motor thus far derived from clinical and anatomical study is of diagnostic value only in consequence of the fact that it increases the tendency to binocular paralysis in nuclear lesions, but that this decussation causes characteristic combinations has not as yet been demonstrated. He points out that if the anatomy of the nucleus as described by Kolliker and Bach is accepted, a monocular nuclear palsy involving all the branches of the third nerve would be impossible. Lesions on the one side would necessarily implicate those intermingling fibers which have crossed over from the opposite side and he maintains that it has never been anatomically demonstrated that the nuclear lesion can involve all or even the majority of the muscles of one eye governed by the third nerve without affecting the muscles of the other eye. The diagnosis of monocular palsy must be made with reserve in all cases of even partial monocular ophthalmoplegia. He quotes the case reported by Starr of partial

external ophthalmoplegia of both eyes due to embolus in the tegmentum, and criticises the conclusions that, if one or two of the muscles of the eyeball supplied by the third nerve are affected, others escaping, the lesion lies in the tegmentum of the crus cerebri between the nuclei of origin and the point of exit of the third nerve; one or both eyes may be affected, but both eyes are rarely affected in the same way. Making exceptions only in cases of post-diphtheric ocular paralysis, Adt would say that in a case of monocular ophthalmoplegia with sudden onset affecting any of the muscles which move the eyeball supplied by this third nerve, others escaping, the lesion lies in the tegmentum of the crus cerebri and that in case of binocular paralysis of this form with sudden onset the lesion lies in the nucleus of the third nerve in the floor of the aqueduct of Sylvius. These rules are also applicable to a great extent in cases with chronic onset, though lesions of the base of the brain or in the orbit implicating some of the fibers of the third nerve may in rare instances cause similar forms of paralysis.

85.—See abstract in THE JOURNAL, xxxvi, p. 1491.

86. **The Blood Count at High Altitudes.**—The experiments of Campbell and Hoagland lead to the following conclusions as to the rapid increase of the blood count as we ascend: "1. The blood count increases as we ascend (without exertion) at the rate of 50,000 corpuscles per cubic centimeter of blood per thousand feet. 2. The pulse rate increases in the same ratio as the blood count, rising as the pulse rises, and in like proportion falling when the pulse rate falls, showing that the heart seeks to overcome the changes brought about by the lessened barometric pressure. 3. The increase is not a true multiplication of the blood corpuscles, but is due to a changed vasomotor condition in the peripheral vessels incident to diminished barometric pressure. This condition of vasomotor control of circulation and blood count was demonstrated in the various experiments made, where it is shown that the count can be increased or diminished by any means that will dilate or contract the peripheral capillaries. 4. This is further demonstrated by the experiments on rabbits, which showed the same increase as man, and by the mesenteric count demonstrated that the external capillary count was increased at the expense of the internal abdominal circulation. 5. The increase in the blood count disappears and the heart's action returns to the normal when we return to the altitude from whence we started. This is another confirmation of the fact that the increase is a fictitious one, and is due to a diversion of the blood current incident to diminished barometric pressure. 6. The dilatation of the external capillaries (skin and lungs) would not alone account for all the increase, but with this dilatation we have another effect of diminished barometric pressure, viz., diminished arterial tension. With vessels of an increased caliber and a heart with a diminished force we can plainly see that we will have more or less of a temporary stasis in the dilated capillaries. In the course of time Nature seeks to adjust an equilibrium in the economy of those who live at high altitudes. The heart becomes more forcible by the strengthening of its muscles, and the circulation becomes more equitable. Hence the gradual decline in the blood count (Solly) of those who have remained for some time at a high altitude. 7. The want of increase of hemoglobin in proportion to the increase of blood count in ascents is accounted for by the fact that the blood corpuscles, the carriers of the hemoglobin, are not increased at once in high altitudes. After remaining some time at a high altitude the true increase in blood corpuscles takes place, and with it the increase of hemoglobin."

87. **Contusions of the Abdomen.**—Stewart's article is a review of the reported facts in regard to contusions of the abdominal viscera.

93.—See abstract in THE JOURNAL of September 14, p. 713.

111. **Mental Weakness of Women.**—This translation from the German of Professor Mobius maintains that woman is inferior in her brain development, especially in those parts associated with mentality and that this condition exists from birth. Woman is instinctive, animal-like, dependent; on this depends her attractiveness. If woman were not physically and mentally weaker than man with her emotional tendencies, she would be extremely dangerous. Her lack of creative ability is manifest. Her learning powers are quickly lost. While we consider woman mentally weaker than man, nothing to her detriment is thus implied. Her accomplishments differ from those of man. This differentiation seems to be a wise provision of Nature. She learns quicker than man, but loses the faculty earlier. The mental crippling effects of marriage are remarked upon and especially the changes of old age.

121. **Tonsillitis.**—The two chief types of tonsillitis, follicular and parenchymatous, are described by Gray, who points out the difficulties of differential diagnosis from diphtheria and at times the absolute necessity of the bacteriologic test. He believes we will find eventually that tonsillitis is due to specific bacteria, and that we are in error if we allow the cases to be closely associated for any length of time with other individuals.

134. **The Double-Knife in Histo-Pathology.**—Gradwohl calls attention to the value of the double-knife in making pathologic examinations and sums up the reasons why we should use this method of examination. 1. Where there has been a hemorrhage into the tissue, we can see it best in the fresh specimen, getting a better idea of the age of the hemorrhage. Hematoidin crystals can be made out, also amorphous yellow hemosiderin. 2. Necrotic changes can as well be investigated in the fresh specimen. 3. Atrophy is easily made out. Should we want to examine the muscles and nerves in atrophy the use of maceration fluids are necessary. 4. Cloudy swelling and parenchymatous degeneration can be seen only in the fresh specimen. To differentiate this condition from fatty changes use acetic acid which dissolves the intercellular nuclei. 5. Fat changes can be seen by the use of acetic acid, ether and chloroform and osmic acid staining. 6. Hyalin and colloid degeneration can be well studied in this way. 7. The microchemistry of amyloid degeneration can be best solved in the fresh specimen. 8. Inflammation of tissue in general can well be studied in the unstained fresh specimen, but if staining is desired, dip the specimen in methyl green. 9. Tumors of various sorts, if of good consistence, can be diagnosed in this way. The technic of the use of the double-knife consists in arranging the blades at a suitable distance, dipping the knife into water so as to secure a film of water between and over them, holding the knife perpendicularly to the surface to be cut, bringing it firmly down upon the organ, imitating the bow-string movement of the violinist, and swerving the instrument from side to side so as to release the specimen; again dip the blades in water and the specimen floats out and it can then be mounted.

135. **Surgical Operations on the Aged.**—Meisenbach finds that the aged bear capital operations very well and that age *per se* is no contra-indication to operation, other things being equal. The aged, under proper conditions, should be given the benefit of our skill in surgical work, but we must bear in mind that the aged do not bear well the loss of heat and blood.

142. **Malarial Hemoglobinuria.**—Lerch gives certain facts of his experience as regards malarial hematuria in a swampy wooded region in Louisiana. There seems to have been a predisposition, and men were almost exclusively attacked by this special symptom. He says that having here proper conditions, viz., a particular parasite, climate favoring the condition, individuals that have suffered from repeated malarial attacks with serious damage, blood saturated with toxins, faulty metabolism, and the idiosyncrasy above mentioned we can readily understand that then, and then only, the phenomena of hemoglobinuria may be provoked by a number of direct causes that under other conditions would appear to be trivial. Quinin hemoglobinuria is also briefly mentioned. The parasite in the patient is the primary cause; quinin acts only as the provoking agent. He believes that quinin is a specific, but it must be understood that it has no curative influence on hemoglobinuria. All it does is to destroy the parasite and it does this thoroughly. Its continuous administration is injurious. Those

that do not yield with a few doses are not due to the parasite, but are post-malarial. Rest is of utmost importance; fresh air, oxygen treatment is justified; proper elimination, bathing, treatment of anemia, etc., and proper diet are all noticed.

British Medical Journal, November 2.

Local Treatment in Diseases of the Upper Air-Passages. Sir Felix Semon.—The author commences the lecture with remarks on the tendency to overdo surgical treatment, and says that the local treatment of ailments of the upper air-passages is not an exception to the rule and has of late years been considerably overdone. The question as to who are the greatest sinners, the profession or the public that permits this sort of treatment, is noticed; he does not think it fair to lay it altogether on the patients, though they are apt to rush into the "non-repellant arms of surgery." Every specialist has some pet operation of his own to which he resorts, and the personal element enters largely into all questions of treatment both as regards the patient and the medical advisers. Our views as to the general principles of treatment of the air-passages are apt to be changed by every new discovery. For the purpose of the lecture he divides the pathologic conditions into the following categories: 1, affections of purely local character; 2, local manifestations of general disorders; 3, local manifestations of the nose and throat dependent on local disease in correlated areas; 4, affections of the upper air-passages supposed to exercise an influence upon other organs and parts of the body, either direct or reflex; 5, local symptoms of sensations of obscure origin. All these overlap each other to a certain extent. In the conclusion of his course he proposes to make some observations on the necessity of a proper proportion being observed between the gravity of the disease and that of the interference. This first lecture deals with the purely local affections of the air-passages and he enumerates the conditions where interference is essential, such as the removal of papilloma, fibroma, complete nasal obstruction, chronic frontal sinus empyema, removal of foreign bodies, etc., and malignant disease of the larynx. We should shake off the belief in the incurability of cancer and not hesitate to operate when it exists while the mischief is still purely local. He thinks, however, that interference with every little deviation, such as nasal spurs, little suppurations in the middle meatus, or every little bunch of adenoid tissue in the vault of the pharynx is not demanded. It is a bad practice for physicians, more and more the fashion, to frighten, perhaps unintentionally, by reciting all the possible contingencies that might arise if the operation was not performed. There should be no hurrying patients into the operation, unless there is good reason for it. He takes up the question of adenoids, pointing out the surgical enthusiasm and the reaction which has taken place to some extent with respect to operation for this disease. As regards the breathing exercise treatment he has an utter lack of confidence in it as a curative method in this condition. As regards operation he divides adenoids into three classes: 1. As to whether they cause (*a*) permanent, (*b*) periodical or transitory, or (*c*) no symptoms. In the first class where respiratory obstruction, open mouth, snoring, thick voice, deafness and the peculiar deformation of the face and chest and general debilitated state of health exist, he considers operation absolutely indicated. In the second class in which are free intervals and alternate periods of obstruction and impairment of hearing, or attacks of earache, the question is more difficult. If the patient is brought to you at his worst with the definite statement that the attacks only occasionally occur and last a short time and you find some soft swelling of the lymphoid tissue, but no deafness or organic ear disease, it would be better to postpone the operation until the symptoms are more decided. If you are in doubt as regards it, lay a clear and non-alarming statement before the parents and let them decide themselves. When adenoids give no symptoms he thinks they should be let alone. There is often not an inconsiderable amount of lymphoid tissue in the vault of the pharynx that has never done any harm. As regards reflex neuroses he is a skeptic, especially those due to adenoids. As regards operation he says the thing is to avoid recurrences, and thorough operation is the best assurance of this. He describes his own method of having the child in the recumbent position with the head well over the table so that there is no danger of blood or loose pieces of adenoid getting into the larynx. The operation should not be finished until the operator by thorough digital observation has convinced himself that there is not a vestige of lymphoid tissue protruding over the surface of the mucous membrane left behind. In conclusion he says, in all purely local affections of the upper air-passages there are certain cases in which all reasonable men will agree that local treatment is required, and others that the moderate section at any rate will be unanimous that it is not. Between these two large classes there is the very large intermediate one in which everything is the question of degree and in which opinions may legitimately differ as regards the local treatment. If we err at all at the present time the tendency is to err by doing too much operating. He quotes Talleyrand's celebrated counsel to a young diplomatist: "Above all, not too much zeal!"

The Dublin Journal of Medical Science, October.

The Blood Corpuscles in Enteric Fever. W. A. Winter.—As there seems to be some obscurity in regard to the leucocytic condition of the blood in enteric fever, Winter has investigated the subject, comparing the relative frequency of white and red corpuscles, also the lymphocytes, large mononuclear leucocytes, polymorphonuclear leucocytes, and eosinophile cells, using Simon's method in estimating the number of leucocytes. At the time of starting this investigation he was not aware of the work of Thayer on the subject or he would have modified his methods to some extent. He gives a comparative table showing the averages of each week compared with Professor Thayer's results. His conclusions are summed up in the following: "1. The number of red blood corpuscles gradually diminishes as the fever progresses, but with the establishment of convalescence regeneration sets in. 2. The number of leucocytes is diminished throughout the course of the fever. This rule does not hold good in all cases, but is so constant that if, in a given case of a non-eruptive fever, the number of leucocytes is normal or subnormal, it would be a strong point in favor of the diagnosis of enteric fever. 3. There is a progressive diminution in the percentage of the polymorphonuclear cells which continues into the stage of early convalescence. 4. The percentage of the large mononuclear leucocytes is increased through the whole course of the fever, and continues into the stage of early convalescence. 5. The percentage of lymphocytes is increased throughout the fever, the increase being most marked in the stage of convalescence. 6. While the fever lasts the percentage of eosinophile cells is subnormal, but with the establishment of convalescence it again reaches and may even pass the normal level." His results in the main agree with those of Ehrlich and Thayer, but disagree with those of Courment and Barbaroux, whose opinion that hypoleucocytosis is due to a decrease in the lymphocytes with possible increase in the polynuclear leucocytes; that this decrease in the percentage of lymphocytes is seen in the stage of convalescence is directly opposed to Winter's experience.

Medical Press and Circular, October 23.

The Asphyxial Factor in Nitrous Oxid Anesthesia. T. Percy C. Kirkpatrick.—The author points out the possible dangers of asphyxia in nitrous oxid anesthesia. Fortunately, the extreme conditions are not commonly met with, but there are objectionable ones that should be avoided. In the first place is the jactitation so commonly met with in gas anesthesia which is really the chronic convulsions of the second stage of asphyxia and may easily be avoided by giving the patient more air. Another phenomenon even more annoying is the struggling which he thinks is also due to the want of oxygen. In many cases the only evidence of asphyxia which may be present is the increased frequency and depth of respiration. It is important to recognize this as an indication of what will follow if it is neglected and because over-stimulation of the respiratory center is apt to be followed by a period of apnea, which may cause trouble. Ordinarily the condition is devoid

of danger, but with weak heart or degenerated vessels it might be serious, and it is almost always followed by violent headache after recovery. The swollen state of the tongue sometimes impedes manipulations about the teeth in gas asphyxia, and is due to the asphyxiated stagnation of the blood. This also favors hemorrhages of the sockets of extracted teeth, thus annoying the operator and when time can only be counted in seconds this is a matter of some importance. These remarks apply with as much force to the administration of ether as that of gas, and in the administration of chloroform any asphyxia is a serious risk. The point to be observed is to give the patient enough air to supply the oxygen while we administer gas enough to anesthetize the patient; hence, the value of the combined oxygen and nitrous oxid method. While the circulation is maintained, and the air way clear, one or two respirations will lessen the cyanosis and indicate the onset of recovery. But if these do not occur he will conclude that either the air is not entering the lungs or that the heart is not acting properly. If the pulse continues to beat he concludes that there is obstruction to the air entering the lungs. Here a method of artificial respiration is indicated; possibly tracheotomy is necessary, but if the circulation is at fault it is worse than useless. If the condition of aspnyxia has arisen early during the administration after struggling and is attended with deep cyanosis the case is probably one of overdistension of the heart; while if it occurs later in the administration and comes on suddenly without warning it is most likely due to syncope. In the latter case inversion of the patient is advisable, but with over-distension of the heart this would only make matters worse. In over-distension we should try to modify the heart by intermittent pressure over the precordial area, and possibly also open one of the jugular veins, artificial respiration being kept up continuously in each case.

Age and Sex as Etiologic Factors in Differential Diagnosis of Gastric Ulcer and Carcinoma. WILLIAM MURRELL.—From statistics offered by Welch, Fenwick, Martin, Murrell and others, the author concludes that gastric ulcer is from two to three times as common in women as it is in men, and most of the cases occur in the decade from 20 to 30. On the other hand gastric cancer is a little more common in men, and the majority of cases occur over the age of 50.

The Lancet, November 2.

Human and Bovine Tuberculosis. EDGAR M. CROOKSHANK.—Crookshank expresses himself in full agreement with Koch that if infection occurs at all from the milk and meat of tuberculous cattle, it is of very rare occurrence, but he entirely disagrees with Koch in his statement that human tuberculosis can not be inoculated into cattle. He recalls certain experiments of his own and those of Ravenel and others, and while he notices the contradictory results obtained by Koch, he thinks the facts quite in harmony with the view that human and bovine tuberculosis are distinct varieties of the same disease. Man is not the natural soil of bovine tuberculosis and similarly the cattle are not the natural soil for human tuberculosis. The difference in soil is well shown by the facts in regard to smallpox, from which cattle do not naturally suffer, but in exceptional cases the disease can be grafted upon them and the result is a mild infection; smallpox of man is transformed into a locally-inocular, mild, vesicular malady in cattle and can never again acquire an infectious character. Sheep-pox is another instance where a highly infectious malady when successfully grafted on the human subject becomes a mild non-infectious disorder. All tubercle bacilli can be inhaled and taken in with the food by perfectly healthy individuals without producing tuberculosis. There are instances of direct inoculation of man by bovine tuberculosis. Cooks and butchers may suffer from tubercular nodules, but they undergo caseation and disappear. Human infection can only be exceptional; if it were not so, man would be decimated by the disease. Crookshank does not accept the theory that abdominal tuberculosis in children is due to tuberculous milk. There are plenty of chances for auto-infection of the intestines, and many ways in which the child can be infected by human bacilli through the mouth. Physicians of experience are not so ready to attribute consumption in any form to tuberculous meat or milk, and he quotes Drs. R. Douglas Powell and J. F. Goodhart in evidence of this. The vegetarian races suffer badly from tuberculosis and he thinks if children suffer from it the trouble is rather that they do not get enough milk; their nutrition is insufficient. He calls attention also to the importance of heredity and believes in the direct transmission of it to a greater extent than is generally admitted. The direct contagion of consumptives has also been much exaggerated; at the same time the habit of spitting in public places, in railway carriages and so on, should be prohibited and the sputa of phthisical patients should be disinfected. That the virus of tubercle scattered far and wide becomes a constant source of danger to all who inhale the air is not a theory which is supported by his experience. We must not draw hasty conclusions from experiments on small animals like guinea-pigs. If tuberculosis were readily conveyed from person to person the marriage of individuals who become or are consumptive would be a fruitful source of direct infection; it is not so according to experience. There is a great difference between inoculation and natural infection.

Milk or Whey in Enteric Fever? PRIDEAUX SELBY.—Milk should not be given as a diet to enteric fever patients according to Selby, because it in many cases forms a hard cheesy curd in the stomach. The bacillus typhosus breeds rapidly in milk and toxins are produced. If we can not give milk what can we give? From a suggestion by someone whose name he has forgotten, he was led to employ whey. The result has been to reduce the death rate of his patients from 15.5 to 2.7 per cent. in 73 cases. The whey contains about one-half as much solids as the milk does. It consists of a solution of milk-sugar, with small amounts of fat, albumin and salt, and he gives figures showing how 4 pints of whey may be a sufficient diet for an adult typhoid fever patient. The method of preparation is to stir two teaspoonfuls of rennet into one quart of milk, warming slowly until it curdles. Break up the curd and strain through a fine linen. It can be sterilized in summer and made more palatable by the addition of tea or coffee or other flavoring. The quantity given varied from 1.5 pints to 6 daily. If it is sterilized some lemon juice should be given occasionally to prevent scorbutic symptoms. The amount of emaciation on this diet varies very much, but not more than it does on any of the usual diets for typhoid. The most marked beneficial effects are seen in the clean mouth and tongue and the gradual diminution of the pulse rate, showing its good effect on the heart. He tabulates his cases and analyzes the symptoms. He thinks alcohol is a valuable factor in feeding, and in some cases of weak heart he gives as much as 24 ounces daily before beginning treatment. From 2 to 4 ounces for adults seem beneficial, using brandy or whisky as the patient desires. For the grass-green defecations occasionally met with he has found 5 to 10 grains of salol rapidly curative. In no case has he had to resort to the cold bath. He never allows the patient to be too warmly covered. If the temperature goes above 103 or 104 F. he has him sponged and placed under a cradle with one or two icebags suspended inside and a sheet over the top. This forms a cold-air bath and is quite efficient. He thinks that no treatment will prevent an occasional hemorrhage after ulceration occurs, but he suggests that large doses of salad oil might saturate the sloughing Peyer's patches, and by stopping the supply of nitrogen to bacilli prevent further ulceration. Drugs are needed as a rule only for complications, and he urges practitioners to give this whey treatment a trial.

Bulletin de l'Academie de Medecine (Paris), October 15.

Urinary Casts. PEHU.—Granular tube-casts are characteristic of epithelial nephritis, even in the absence of indications of acute inflammation, and suggest inflammation in the convoluted tubules. The other varieties of tube-casts have little significance in diagnosis; they merely indicate some modification of the process. Hyalin casts generally accompany disturbances in the circulation, but have no characteristic significance. During the acute phase of epithelial nephritis the granular

casts are numerous, small, and the granules compacted together. In this form they indicate active cellular fermentation. In the subacute stage the granular casts are less numerous, larger, especially when secondary sclerosis is appearing, and an occasional hyalin cast is discovered. When the renal affection is passing into the chronic stage, the albuminuria alone persists, owing to the imperfect regeneration of the convoluted tubules and the formation of an actual cicatrix in the kidney. The tube casts vanish and the prognosis is favorable. When the cure is complete there is no further albuminuria nor casts.

Surgical Treatment of Congenital Cleft Palate. EHRMANN.—Instead of completing the palatoplasty at one sitting, Ehrmann postpones the suturing for a week later at farthest, and considers this modification a great advance in the treatment of quite young children. This is indicated in patients between 6 and 12 years who are frail, with their palate mucosa thin, and also in all cases in which there is not an abundant supply of material for the plastic operation. Secondary hemorrhage is impossible when the operation is done in two sittings, and the liability to suppuration is reduced to the minimum. He sutures the uvula with fine silk, inserting the threads before the field is obscured with blood, and uses silver wire for the remainder of the suture. Wolff has recently published four cases in which the patients were operated on when between six and eighteen months old. At the sixth to ninth year speech was entirely normal. Out of 311 operations on the palate, 192 of the patients were less than 7 years old. The best results were attained at about 2 years of age, which has also been Ehrmann's experience. The deformity of the upper jaw consecutive to palatal operations is caused by complications interfering with regular cicatrization, which it should be the surgeon's care to prevent.

Le Nord Medical .(Lille), October 15.

Syphilitic Typhosis. BOURNOVILLE.—When the tongue is moist and the sweat is extremely abundant in a case of apparent typhoid fever, the possibility of a syphilitic typhosis should be borne in mind. The extreme intensity of the headache, eruptive manifestations and their generalization, and the negative serodiagnosis confirm this possibility, especially when there is hyperleucocytosis, decreased number of red corpuscles and decrease in the hemoglobin. Specific treatment will rapidly dispel the typhoid condition. The syphilitic agent may be hypervirulent, or the typhoid may be a superposed infection, or the resisting powers of the organism may be at a low ebb. Bournoville accepts the latter explanation as most probable, as in his experience patients included in this category were always much debilitated from excesses or overwork. The typhoid symptoms appear from the thirtieth to the sixtieth day, usually about the forty-fifth. The abdomen is most sensitive in the right iliac fossa, and the diarrhea is absolutely rebellious. The liver is enlarged, and there is generally alimentary glycosuria, urobilinuria and hypertoxicity of the urine. Only one fatal case has been known, but relapses have sometimes occurred.

Centralblatt f. Chirurgie (Leipsic), November 2.

Functional Tests of the Kidneys in Diagnosis for Renal and Abdominal Surgery. L. CASPER.—THE JOURNAL recently mentioned Casper's announcement at the German Naturforscher Congress of the information to be obtained by separate catheterization of the ureters after the phloridzin test, with determination of the freezing-point of the urine from each kidney. He gives details in this communication. In one case he was able by this means to locate the kidney containing the calculi, impossible to determine by other measures. The tests disclosed that a suprarenal adenoma in one case and cysts in another, did not involve the kidney as supposed. In a fourth patient, the tests differentiated a renal tumor from an appendiceal abscess. In another the differentiation of biliary from renal lithiasis was rendered possible and in three others the negative results of the tests confirmed the diagnosis of simple nephralgia. In sound kidneys the results of the tests are the same on both sides, and a difference between them indicates pathologic conditions. "The sicker the kidney, the lower the values obtained."

Deutsche Med. Wochenschrift (Leipsic), October 24.

Clinical Application of Hemolytic Properties of the Blood. A. LAQUEUR.—About 0.1 c.c. of human blood serum is able to destroy all the red corpuscles in a 5 per cent. mixture of rabbit blood in 0.85 per cent. salt solution. If human blood serum be heated for half an hour to 56 C. it loses the hemolytic property, probably from the destruction by the heat of the "complement" necessary for the process. But it regains it if a small amount of the complete serum be added to it, 0.1 c.c., for instance, to 1 c.c. of the complete serum. Neisser and Doering found this phenomenon constant in all their tests, except in one case in which the blood was derived from a patient in severe uremia. Laqueur has confirmed this phenomenon in two cases of uremia. The addition of the heated serum to the usual proportion of complete serum annuled the hemolytic power of the latter. In one case this phenomenon occurred under his eyes as the patient first showed symptoms of uremia. In another patient with nephritis but no uremia, the serum behaved like normal serum, as was also the case in numbers of other tests with serum derived from other patients, from venesection, placental blood, etc. The blood pressure was extremely high in both the cases of uremia described, and it increased by 15 to 20 mg. whenever there was an exacerbation of the symptoms. Very effective relief was obtained at such times by total wet packs, which were always followed by subjective improvement and fall of the blood pressure. By this means severe uremic attacks were warded off, and the patients succumbed finally to heart failure. It was noticeable that as the fatal termination approached, the blood pressure fell instead of rising with exacerbations, but even when abruptly dropping from time to time, it still remained higher than normal. Two days before death it had fallen to 155 mm. from its previous height of 210 in one case, and to 140 in the other. The determination of the blood pressure in uremia, for which Gaertner's tonometer is admirably adapted in its simplicity, affords not only valuable assistance in diagnosis and prognosis, but also indicates the moment for therapeutic intervention.

Cytodiagnosis of Meningitis. E. BENDIX.—In five cases of tubercular meningitis Bendix found lymphocytes numerous in the cerebrospinal fluid withdrawn by lumbar puncture. In three cases of epidemic meningitis, large polynuclear leucocytes were in the majority, with one exception, in a case protracted through months. In the tuberculous cases, the specific bacilli could be discovered only once. The autopsy confirmed the cytodiagnosis in each case. Bendix considers the presence of polynuclear leucocytes an indication that the process is recent. Lymphocytes, on the other hand, reveal a protracted, chronic process, and hence are valuable in the differentiation of tuberculous from the acute, epidemic variety of meningitis.

Cause of Dacryocystitis. E. RAEHLMANN.—Among 1081 cases of trachoma observed at Dorpat during 1899, the lachrymal sac was affected in 43. Careful anatomic study of these cases, with sections of ten of the sacs, disclosed that the acute dacryocystitis was merely an extension of the typical trachomatous process. The cicatrices that result from the follicular abscesses cause strictures and consequent stenosis. These facts suggest the necessity of appropriate treatment and justify the extirpation of the lachrymal sac in such cases.

Lymphoma Versus Pseudo-Leukemia. E. BECKER.—In this communication from Gerhardt's clinic, various cases of pseudo-leukemia, etc., are described. Analysis of the symptoms and anatomic foundation of these and similar cases has convinced Becker that the designation "pseudo-leukemia" should be discarded. In its place he proposes five groups of affections involving the lymphatic system: 1, lymphosarcomatosis; 2, tuberculous lymphomatosis; 3, syphilitic lymphomatosis; 4, simple hyperplastic lymphomatosis, with the sub-group of infantile splenic anemia, and 5, diffuse lymphomatosis.

Formalin Soap Effective Against Night Sweats in Phthisis. K. DOURN.—Twelve patients have been treated at the Carolahaus in Dresden by inunctions of a 5 to 10 per cent. formalinized olive-oil fluid soap. All were much benefited and the sweats were completely arrested in seven cases. The entire trunk was rubbed energetically with the soap for a minute and the skin massaged at the same time. The soap was then sponged off with a damp cloth and the body carefully wiped dry. The procedure is peculiarly refreshing to the patients and all sleep better after it is applied each evening. The fumes of the formalin affected the conjunctiva in one patient, but she was unwilling to dispense with the treatment on account of this slight drawback.

Muenchener Med. Wochenschrift, October 22.

Tardy Disturbances After Tracheotomy and Intubation. M. PFAUNDLER.—Reviewing the later history after tracheotomy or intubation of 173 children at Escherich's clinic, it was found that the children who had been intubated were as healthy as the same number of average children, and that no connection between any casual affection of the respiratory passages and the intubation could be discovered. But the case was different with the children on whom tracheotomy had been performed. Slight disturbances were evident in 12.5 per cent. of the tracheotomized, and in 18.8 per cent. of those treated by tracheotomy and intubation. Severer disturbances, such as permanent hoarseness, cicatricial tracheal stenosis, chronic cirrhotic pneumonia or pulmonary tuberculosis were noted in 3.5 per cent. of the intubated; in 12.5 per cent. of the tracheotomized and in 31.3 per cent. of the cases in which tracheotomy and intubation had both been applied. Intubation had been used alone in 141 cases, tracheotomy alone in 16 and both combined in 16.

Wiener Klin. Wochenschrift, October 17.

Incarcerated Hernia in the Lateral Abdominal Wall. C. STERNBERG.—A woman of 61 was suddenly taken sick with vomiting and pains in the abdomen ascribed to some indiscretion in diet. A tumor in the left side of the abdomen extended from Poupart's ligament to the costal arch, circumscribed on the outside but less distinctly outlined toward the median line. It was slightly movable and subsided perceptibly during inspiration. It was not tender and was distinct from the genitalia. The tumor resembled a kidney in shape. There was no dulness over the kidneys. The tumor was first noticed four days before the vomiting commenced. An operation was refused and death ensued in four days. The hernial sac included the omentum and a loop of the small intestine, in a subcutaneous tear in the internal oblique. No trauma nor predisposition on the part of the tissues could be discovered, to account for the sudden hernia, but possibly some unusual muscular effort may have induced it. Vulpius was able to find only 12 cases of hernia into the abdominal side wall in 1891; 4 were incarcerated and 2 of these had resulted from physical exertion, 2 from a stab wound. Franz has reported 2 other cases, both subsequent to trauma. Wyss has published a congenital case in an infant with other malformations. Surgical intervention in these cases of hernia into the abdominal wall may save life and the non-recognition of the hernia may entail the severest consequences. Albert describes a case in which the hernia was diagnosed a lipoma and only the operation disclosed the error. In another case it was assumed to be an abscess and incised, thus creating an artificial anus.

October 24.

Indications for Lithotomy Operations. O. ZUCKERKANDL.—Experience with 150 lithotomies and the statistics published by various writers have convinced Zuckerkandl that suprapubic lithotomy should be limited in its application. The mortality ranges from 13.5 to 28 per cent. except in Assendelft's statistics. He operated on children and by the suprapubic route in all his 460 cases. Keith's experience with a similar material treated by lithotripsy showed only a mortality of .5 per cent. in 375 cases. The highest mortality after perineal lithotripsy is only 9.2 per cent., while Freyer reports 1.3, Guyon 2.5, and Zuckerkandl 3.6 per cent. The introduction of perineal lithotripsy marks a great progress in the treatment of stone in the bladder. Lithotripsy is indicated in all cases in which the stones are freely movable in the bladder and the urethra allows the introduction of the instruments. Perineal lithotripsy is indicated when the urethra does not readily allow the passage of stiff instruments, when the prostate is enlarged and the prostatic portion of the urethra is immoderately long or the passage very narrow, provided that the stone is free and accessible to the instrument. Also in case of stricture of the urethra, fistula or callus formation or when there are calculi likewise in the urethra. Perineal lithotripsy may also be indicated in cases in which it is impossible to complete the lithotripsy owing to incarceration of the stone or swelling of the prostate. Suprapubic incision must be resorted to when the stones are so large that the instruments have no play, or when the stones are in a diverticulum, in a deep fundus behind a protruding prostate or in case of encapsulated or impacted stones, in case of concretions around a foreign body or neoplasms of the bladder, and when an abdominal fistula is planned. The permanent catheter is not an absolute protection against general sepsis, and Zuckerkandl drains in the majority of his cases. As a narcotic for lithotripsy, he has been most pleased with 2.5 to 5 gm. of antipyrin, dissolved in 50 gm. of water, injected into the rectum half an hour before the operation is commenced. The anesthesia thus induced was surprisingly perfect, but in cases of irritable bladder, difficult passage through the prostate or when the size of the stones prolongs the operation, superficial chloroform narcosis, preceded by an injection of morphin, is indicated. Cystoscopy will much facilitate the intervention and disclose a diverticulum or an encapsulated or impacted stone and thus warn against lithotripsy alone. The occlusion of the evacuator by a fragment of a stone is avoided by crushing the stones as fine as possible. In two cases he aimed to bring out the stone intact in this way, and after some work with the pump was able to determine that the stone was firmly impacted in the evacuator and was thus removed whole. In two aseptic cases death occurred from septicemia, probably by infection through some slight injury to the urethra, as no evidences of cystitis could be found in the bladder or kidneys. In another case of chronic cystopyelitis, the bladder must have been perforated, whether from a stone or the pumping it was impossible to decide. The operation proceeded without incident, but peritonitis developed a few days later. Twelve of his 95 patients treated by lithotripsy have had the stones recur; phosphates in 9 and urates in 3. No recurrence was known of oxalate stones. After suprapubic lithotomy, complete retention of urine has been occasionally noted, attributable to the forced distention of the bladder. Since he has been operating with the bladder only moderately filled, this sequel has not occurred.

Diagnosis of Aneurysm of the Mesenteric Artery. G. GABRIEL.—The diagnosis is based, 1, on the existence of some primary valvular affection, recent bacterial endocarditis in the case described; 2, on the existence of hemiplegia, which may be either due to softening or a bacterial endarteritis; 3, on the presence of a rapidly growing tumor in the abdomen for which no other cause can be assigned, and 4, on the youth of the patient. The cerebral symptoms may be due to embolism with consecutive softening or to bacterial endarteritis of some artery in the brain with subsequent aneurysm, rupture and hemorrhage into the brain substance.

October 31.

Biologic Relations Between Milk and Serum. E. MORO.—Neither human nor cow's milk possesses bactericidal properties, but Moro has established that the serum of nursing infants is more bactericidal and hemolytic than the serum of others fed on artificial food. The change from mother's milk to artificial food or vice versa alters the serum in this respect.

Two Cases of Malignant Epithelioma of the Vagina with Intact Uterus. H. SCHMIT.—In both cases the patients were permanently cured after the excision of the malignant

chorio-epithelioma. The tumor was formed of a hematoma containing in its center villi and malignant elements of the chorion evidently derived from the villous surface. The facts observed indicate that harmless villi may be transferred to the vagina during pregnancy or delivery and that the tumor develops later from proliferation of the epithelium. It is possible to conceive that the malignant elements might become completely enclosed in the tumor and repeated hemorrhages induce their necrosis, resulting finally in a spontaneous cure.

Influence of "Stasis-Hyperemia" on Bone Formation. A. BUM.—In a series of experiments on young dogs and rabbits. a ligature was applied to the leg above the fracture, an hour or two each day. It was found that the callus had grown much more luxuriantly on the side on which stasis had been induced in this way. The periosteal callus exhibited much more pronounced calcification and ossification. The fractures were alike on each side.

Giornale Della Accad. di Med. (Turin), August-September.

The Diazo-Reaction. M. LAMPUGNANI.—From analysis of the diazo-reaction as it occurred or failed to occur in 500 patients and a number of healthy persons, Lampugnani concludes that it is the expression of a pathologic process in the organism, connected with the elevation of the temperature. The temperature may be elevated without the reaction, but the latter never occurs with normal temperature. Besides the elevation of the temperature, which is a necessary but not the unique cause of the phenomenon, there must be some other factor, possibly the production of some reducing substance, the immediate effect of which is the diazo-reaction. The pigments in the urine evidently co-operate in the production of the reaction. It was positive in 31 out of 49 cases of typhoid fever and in 9 out of 26 cases of pulmonary tuberculosis. The tuberculous patients who exhibited the reaction all died soon afterward. The diazo-reaction has therefore considerable value for the diagnosis of typhoid fever and for the prognosis of tuberculosis. The tests were all negative in nervous, gastric, renal and rheumatic affections, and in acute and chronic intoxications and heart disease, but the reaction was obtained in the 4 cases of malaria examined and in 17 of erysipelas. It never occurred in the healthy subjects nor in rabbits.

Gastric Digestion in the Insane and the Cure of Sitophobia. G. R. RUATA.—Lavage of the stomach is one of the most useful means at our command in the treatment of the insane, from several points of view. Ruata learned from it that morbid psychic states, accompanied by depression, are characterized by a diminution or disappearance of the secretion of hydrochloric acid, while on the other hand it becomes exaggerated during a condition of agitation and excitement. The hyperemia or anemia of the cerebral cortex makes its influence felt throughout the organism on all the vital functions, exaggerating or depressing them. The secretions altered in consequence reflect in their turn on the functions of the cortex, producing sitophobia in some cases and aggravating the psychosis in all. Hypochlorhydria was almost the rule in the phase of depression in mania, alcoholic pseudo-paralysis and amentia confusionalis, and great benefit was derived in these cases from the systematic administration of hydrochloric acid. In all the insane subjects the proportion of total acidity and of uncombined hydrochloric acid was less than normal, although the peptones were constant. The administration of hydrochloric acid conquered even the most rebellious cases of sitophobia in his experience.

Tamponing the Uterus in Cesarean Section. G. VICARELLI.—The danger of hemorrhage and of infection is avoided by tamponing the uterus after Cesarean section through the abdominal wound, with a strip of gauze five yards long by ten centimeters wide. The uterus contracts over the tampon and holds it firm. It does not interfere in any way with the regular discharge of the lochia nor the involution of the uterus nor the normal cicatrization of the wound. It can be extracted through the vagina in one to three days without the slightest trouble. The tampon renders it possible for the operation to be performed at any moment without waiting for labor as there is no fear of hemorrhage from inertia of the uterus. Vicarelli describes seven patients thus treated, all severe cases of deformed pelvis, the results exceptionally fine for both mother and child.

Spinal Cocainization in Obstetrics. G. VICARELLI.—The conclusions from Vicarelli's experience with eleven maternity cases are unfavorable to this method of analgesia in obstetrics.

St. Petersburger Med. Wochenschrift, October 12.

The Mental and Moral Disposition of Tuberculous Subjects. H. NEUMANN.—Various writers have described the sluggish memory, the inability to think or read on subjects requiring thought, etc., which they have noticed in consumptives, and have tried to evolve a type of psyche characteristic of tuberculosis. Neumann does not agree with them and attributes the laziness of thought and action and the heightened sexual appetite, etc., to the idleness of the inmates of a sanitarium who devote all their attention to eating, sleeping and reclining at stated hours, at most reading novels to while away the time. He thinks it is the duty of those in charge of sanitariums for tuberculosis to include some stated work in the course of treatment and compel the patients to do a certain task each day, individualized to the patient. This is less necessary in case of working people, as they do not lose the habit of working in their two or three months' stay, but a young merchant, for example, might be encouraged to study a foreign language, a student to review certain studies, etc. The success of the treatment will be enhanced if the physician systematically applies measures of this kind to prevent the development of neurasthenia, hysteria and hypochondria.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A TEXT-BOOK OF MEDICINE for Students and Practitioners. By Dr. Adolf Strümpell, Professor and Director of the Medical Clinique at the University of Erlangen. Third American Edition. Translated by Permission from the Thirteenth German Edition, by Herman F. Vickery, A.B., M.D., Instructor in Clinical Medicine, Harvard University, and Philip Coombs Knapp, A.M., M.D., Ex-President of the American Neurological Association. With Editorial Notes by Frederick C. Shattuck, A.M., M.D., Jackson Professor of Clinical Medicine, Harvard University. With 185 Illustrations in the Text, and One Plate. Cloth. Pp. 1242. Price, $6.00. New York: D. Appleton & Co. 1901.

ANATOMY, Descriptive and Surgical. By Henry Gray, F.R.S., Fellow of the Royal College of Surgeons. Edited by T. Pickering Pick, F.R.C.S., Consulting Surgeon to St. George's Hospital; and Robert Howden, M.A., M.B., C.M., Professor of Anatomy in the University of Durham. A Revised American, from the Fifteenth English Edition. With 780 Illustrations, Many of Which Are New. Cloth. Pp. 1257. Price, $5.50 net. Philadelphia and New York: Lea Brothers & Co. 1901.

THE PRACTICE OF OBSTETRICS, by Many Authors. Edited by Charles Jewett, M.D., Professor of Obstetrics and Gynecology in the Long Island College Hospital, New York. Second Edition, Revised and Enlarged. Illustrated with 445 Engravings, 48 of Which Are in Colors, and 36 Colored Plates. Cloth. Pp. 781. Price, $5.00 net. New York and Philadelphia: Lea Brothers & Co. 1901.

PUBLIC HEALTH REPORTS. Issued by the Supervising Surgeon-General Marine-Hospital Service, Under the Act of Congress Granting Additional Quarantine Powers and Imposing Additional Duties upon the Marine-Hospital Service. Approved Feb. 15, 1893. Vol. XV. Parts 1 and 2. Nos. 1 to 52. Cloth. Pp. 3182. Washington: Government Printing Office. 1901.

DISCIPLES OF ÆSCULAPIUS. By Sir Benjamin Ward Richardson, M.D., F.R.S. With a Life of the Author by His Daughter, Mrs. George Martin. In Two Volumes. Vols. I and II. With Portraits and Illustrations. Cloth. Pp. 424. Price, $8.00 net. New York: E. P. Dutton & Co. 1901.

A TEXT-BOOK ON DISEASES OF THE EAR, NOSE AND THROAT. By Charles H. Burnett, M.D., E. Fletcher Ingals, M.D., James E. Newcomb, M.D. With Numerous Illustrations. Cloth. Pp. 716. Price, $5.00. Philadelphia and London: J. B. Lippincott Co. 1901.

PROCEEDINGS OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY. September. Paper. Pp. 12. Philadelphia: Published by the Society. 1901.

CHIMICA CLINICA. Dott. Raffaele Supino, Assistence alla Clinica Medica Generale di Pisa. Cloth. Pp. 198. Milano: Ulrico Hoepli. 1902.

L'EPILESSIA. Dottor Paola Pini. Eziologia-Patogenesi Cura. Cloth. Pp. 277. Milano: Ulrico Hoepli. 1902.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Oct. 31 to Nov. 6, 1901, inclusive:

Dallas Bache, colonel, assistant surgeon-general, U. S. A., to his home at Los Angeles, Cal., to await retirement from active service.

Peter W. Beckman, contract surgeon, now in San Francisco, Cal., to proceed to Fort Du Quesne, Utah, for duty at that port.

Horace D. Bloomberg, lieutenant, asst.-surgeon, U. S. A., relieved from further duty at the Army Medical School, to report for duty at the U. S. General Hospital, Fort Bayard, N. M.

George C. Craig, contract surgeon, now at Rock Island, Ill., to report to the commanding officer, Rock Island Arsenal, for duty.

William R. Eastman, lieutenant, asst.-surgeon, U. S. A., recently appointed to report in person to Colonel W. H. Forwood, assistant surgeon-general, U. S. A., president of the faculty of the Army Medical School, Washington, D. C., for the prescribed course of instruction.

Guy L. Edie, major and surgeon, U. S. A., member of an examining board at Columbus Barracks, Ohio.

Robert C. Eve, contract surgeon, previous orders annulling contract, revoked; he is relieved from duty in the Department of the East, and assigned to Fort Sam Houston, Tex., to relieve Contract Surgeon G. Graham Watts, U. S. A.

George H. R. Gosman, lieutenant, asst.-surgeon, U. S. A., member of an examining board at the U. S. Military Academy, West Point, N. Y., vice Captain Franklin M. Kemp, asst.-surgeon, U. S. A., relieved.

Henry S. Greenleaf, lieutenant, asst.-surgeon, U. S. A., member of an examining board at the Presidio of San Francisco, Cal., vice Lieutenant John A. Murtagh, asst.-surgeon, U. S. A., relieved.

Ernest K. Johnstone, major and surgeon, Vols., having tendered his resignation, is honorably discharged from the service of the United States, to take effect Nov. 2, 1901.

Palmer H. Lyon, captain, asst.-surgeon, Vols., now at Lyons, N. J., will, on the expiration of his present sick leave, proceed to Fort Hamilton, N. Y., for temporary duty, to relieve Lieutenant Edwin P. Wolfe, asst.-surgeon, U. S. A.

Walter D. McCaw, major and surgeon, U. S. A., from the Division of the Philippines, to report to the Surgeon-General, at Washington, D. C., for instructions.

Clarence B. Millhoff, lieutenant and asst.-surgeon, U. S. A., resignation accepted, to take effect Nov. 5, 1901.

Edward L. Munson, captain and asst.-surgeon, U. S. A., detailed for duty as assistant professor of hygiene at the Army Medical School, Washington, D. C.

Robert M. O'Reilly, lieutenant-colonel and deputy surgeon-general, U. S. A., from Fort Monroe, Va., to Washington, D. C., on official business pertaining to the Medical Department, and on the completion of this duty to rejoin his proper station.

Charles A. Ragan, lieutenant and asst.-surgeon, U. S. A., recently appointed, to report in person to Colonel W. H. Forwood, assistant surgeon-general, U. S. A., president of the faculty of the Army Medical School, for the prescribed course of instruction.

Charles Richard, major and surgeon, U. S. A., member of an examining board at Fort Leavenworth, Kan.

Edward G. Seibert, contract surgeon, to report in person to Major Edward C. Carter, surgeon, U. S. A., attending surgeon, Washington, D. C., for duty.

Paul Shillock, major and surgeon, U. S. A., member of an examining board at Fort Riley, Kan., vice Major Charles E. Woodruff, surgeon, U. S. A., relieved from this duty.

Herbert M. Smith, lieutenant and asst.-surgeon, U. S. A., relieved from duty at the Army Medical School, Washington, D. C., to report for post duty at Fort Leavenworth, Kan., Nov. 2; member of an examining board at Fort Leavenworth, Kan.

Alexander N. Stark, captain and asst.-surgeon, U. S. A., from temporary duty at Fort Monroe, Va., to rejoin his proper station at Fort McHenry, Md.

Sandford H. Wadhams, lieutenant and asst.-surgeon, U. S. A., member of an examining board at Columbus Barracks, Ohio.

Philip G. Wales, captain and asst.-surgeon, U. S. A., from Fort Du Quesne, Utah, to Denver, Colo., for duty as attending surgeon and examiner of recruits at that place.

G. Graham Watts, contract surgeon, on being relieved by Contract Surgeon R. C. Eve (see above), will report in person to the chief surgeon, Department of Texas, for annulment of contract.

Edwin P. Wolfe, lieutenant and asst.-surgeon, U. S. A., from Fort Hamilton, N. Y., to duty at Fort Bliss, Texas.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Nov. 9, 1901:

Surgeon F. Anderson, detached from the Naval Dispensary, Washington, D. C., November 7, and ordered to the *Alabama*, November 9, as relief of Surgeon E. H. Green.

Surgeon E. H. Green, detached from the *Alabama*, November 9, and ordered to duty as a member of the medical examining board, Washington Navy Yard, Nov. 15, as relief of Surgeon A. C. H. Russell.

Medical Director J. C. Ayers, retired from active service, November 3, 1901, by operation of law, under the provisions of Section 1444, Revised Statutes, upon which date he will have reached the age of 62 years; with rank and three-fourths the sea-pay of the next higher grade, under the provisions of Section 11, Navy Personnel Law.

Asst.-Surgeon R. M. Young, detached from the *Columbia* and ordered to the *Constellation* for temporary duty.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the fourteen days ended Oct. 31, 1901:

Surgeon R. D. Murray, appointed as appraiser to place valuation on property of State Board of Health of Florida used for quarantine purposes at Key West, Fla.

Surgeon F. W. Mead, granted leave of absence for one day.

Surgeon J. H. White, appointed as appraiser to place valuation on property of State Board of Health of Florida used for quarantine purposes at Boca Grande, Fla. To proceed to Brunswick quarantine as appraiser, and to the South Atlantic quarantine station on special temporary duty.

Asst.-Surgeon John McMullen, granted leave of absence for seven days.

Asst.-Surgeon H. B. Parker, relieved from duty at New Orleans, La., and directed to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for duty. Bureau order of Oct. 18, 1901, directing Asst.-Surgeon Parker to proceed to Washington and report to the Director of the Hygienic Laboratory for duty, suspended.

Asst.-Surgeon C. C. Pierce, to proceed to Mullet Key, Fla., for special temporary duty.

A. A. Surgeon Frank Boyd, granted leave of absence for twenty-five days from November 1.

A. A. Surgeon V. B. Gregory, relieved from duty at Tampico, Mex., and directed to proceed to Rio de Janeiro, Brazil, for duty in the office of the U. S. Consul General.

A. A. Surgeon J. W. Hargis, granted leave of absence for ten days from October 19.

Hospital Steward C. W. Stephenson, granted leave of absence for twenty-three days from November 4.

Surgeon H. W. Austin, bureau letter of Sept. 28, 1901, granting leave of absence for one month, amended so that said leave shall be for twenty-one days only.

P. A. Surgeon H. D. Geddings, to assume temporary command of Hygienic Laboratory during absence of P. A. Surgeon M. J. Rosenau.

P. A. Surgeon A. R. Thomas, to proceed to Liverpool, England, for duty.

Asst.-Surgeon John McMullen, granted four days' extension of leave of absence.

A. A. Surgeon B. F. Duke, granted fifteen days' leave of absence from October 25.

A. A. Surgeon R. E. Ebersole, granted three days' leave of absence under paragraph 181 of the regulations.

Hospital Steward, J. E. Beck, granted seven days' leave of absence, from Oct. 20, 1901, under paragraph 181 of the regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Nov. 9, 1901:

SMALLPOX—UNITED STATES.

Illinois: Peoria, Oct. 1-31, 6 cases; Springfield, Oct. 2-Nov. 2, 26 cases.
Iowa: Ottumwa, Sept. 28-Nov. 2, 31 cases.
Kansas: Wichita, Oct. 19-26, 3 cases.
Kentucky: Lexington, Oct. 25-Nov. 2, 3 deaths.
Louisiana: New Orleans, Oct. 25-Nov. 2, 7 cases.
Massachusetts: Boston, Oct. 19-Nov. 2, 22 cases, 2 deaths; Newton, Oct. 19-26, 2 cases.
Michigan: Detroit, Oct. 19-Nov. 2, 2 cases.
Nebraska: Omaha, Oct. 19-Nov. 2, 14 cases; South Omaha, Oct. 17-24, 6 cases.
New Jersey: Camden, Oct. 19-26, 5 cases, 1 death.
New York: Oct. 26-Nov. 2, Elmira, 1 case; New York, 5 cases, 4 deaths.
Ohio: Youngstown, Oct. 12-19, 2 cases.
Pennsylvania: Allegheny City, Oct. 18-25, 1 case; Lebanon, Nov. 2, 2 cases; Norristown, Oct. 26-Nov. 2, 7 cases, 1 death; Philadelphia, Oct. 19-Nov. 2, 111 cases, 22 deaths; Pittsburg, Oct. 26-Nov. 2, 6 cases.
Vermont: Burlington, Oct. 26-Nov. 2, 3 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Oct. 6-19, 6 cases.
Belgium: Antwerp, Oct. 6-12, 2 cases, 1 death.
Canada: Halifax, Oct. 19-Nov. 2, 13 cases; Quebec, Oct. 26-Nov. 2, 41 cases; Winnipeg, Oct. 26-Nov. 2, 1 case.
Colombia: Panama, Oct. 20-28, 300 cases.
Great Britain: Oct. 12-19, Liverpool, 1 case; London, 172 cases, 12 deaths.
Russia: Moscow, Oct. 5-12, 5 cases, 1 death; Odessa, Oct. 12-19, 3 cases; Warsaw, Oct. 7-14, 3 cases.
Uruguay: Montevideo, Aug. 24-Sept. 14, 75 cases, 11 deaths.

YELLOW FEVER.

Colombia: Bocas del Toro, Oct. 15-23, 2 cases.
Mexico: Vera Cruz, Oct. 19-26, 17 cases, 2 deaths.

CHOLERA.

India: Bombay, Oct. 1-8, 3 deaths; Calcutta, Sept. 28-Oct. 5, 3 deaths.

PLAGUE—UNITED STATES AND INSULAR.

California: San Francisco: Oct. 20-30, 1 case, 1 death.
Philippines: Manila, Sept. 7-21, 5 cases, 3 deaths; Taguig, Sept. 7-14, 1 death.

PLAGUE—FOREIGN.

Great Britain: Glasgow, Nov. 1, 4 cases; Liverpool, Oct. 30, several cases, 2 deaths.
India: Bombay, Oct. 1-8, 174 deaths; Calcutta, Sept. 22-Oct. 5, 19 cases.
Turkey: Samsoun, Oct. 1, 9 cases, 1 death.

The Journal of the American Medical Association

VOL. XXXVII. CHICAGO, ILLINOIS, NOVEMBER 30, 1901. No. 22.

Address.

CHAIRMAN'S ADDRESS.

DELIVERED BEFORE THE SECTION ON PATHOLOGY AND BACTERIOLOGY, AT THE FIFTY-SECOND ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

LUDVIG HEKTOEN, M.D.
CHICAGO.

A provision in the constitution makes it incumbent upon the chairman of each Section to deliver an address at the beginning of the annual meeting. In this address he shall set forth the progress of the year in the field covered by the particular Section. The day for formal addresses of this sort is rapidly passing away, and I shall not attempt a detailed review of the progress in pathology and bacteriology during the past twelve months. That the American Medical Association has assumed the sponsorship of a separate section in these branches is, I think, evidence of the general progress that pathology and bacteriology are now making in this country. Societies and separate sections, like hypotheses, are not to be multiplied beyond necessity, but criticism of the tendency to multiply medical societies is hardly applicable to this case because it is an effort to extend the usefulness and influence of a large, national organization of great strength.

It is true, as has been said by others, that much of the work in pathology and bacteriology should be brought out in the clinical sections, that our members should cooperate with the clinicians. Properly managed, our section will help, not hinder this co-operation, because at the same time as we may participate in other sections there is now an opportunity to discuss questions of special interest to pathologists and bacteriologists, an opportunity that it is hoped will bring together each year a group of men of common interests. The constitution and by-laws of the Association give to each section virtual autonomy. This section has the power to regulate its own workings to its best advantage. Experience will soon demonstrate the directions that efforts should take in order to utilize fully the opportunities offered for mutual exchange of opinion, for diffusion of the results of investigation, and of new methods. Special effort should be made at this early stage in the history of the section to secure accurate minutes of the proceedings and to exercise careful scrutiny of the material published in THE JOURNAL as read at our meetings.

The pathologic exhibit which is now in the hands of the section, offers an unexcelled opportunity for the demonstration, to large numbers, of specimens, apparatus, methods of working and of teaching. Naturally, the territory tributary to the place of meeting may be expected to be most largely represented in the annual exhibit. We owe a large debt of thanks to Dr. Frank B. Wynn, the Secretary of the Section, who as Chairman of the Committee on Pathologic Exhibit has shown an unusual ability for the work, the results of which speak for him more strongly than my words.

It has been said recently by competent authority that the opportunities for scientific work in pathology and bacteriology are now highly developed in this country. No one familiar with the situation will take exception to this pleasing statement. Much remains to be done, however, in properly organizing the work in pathology and bacteriology in the various centers. The relations of the teachers of these branches in many of the colleges are, I believe, far from satisfactory. This is also true in regard to the pathologic work in the majority of our public hospitals of various kinds. Unfortunately, the present mode of management is not always conducive to the development in them of a scientific spirit, and the public governing bodies have yet to learn that the pathologist is as worthy of a hire as any other laborer. It is clear, too, that the best interests of pathology and bacteriology demand that bodies now scattered should be organized; much teaching that can be better done and better paid in a single institution has been divided among several, none of which, perhaps, can offer inducements to keep good men permanently. Yet the possibilities for careers in pathology and bacteriology in this country are rapidly equaling in opportunity and reward those of older countries and of other sciences in this country.

An encouraging feature is the steadily increasing interest manifested in medicine by our universities. The modern American university is fast becoming, as it ought to be, a factory of new knowledge in which research and criticism flourish and in which culminate the tops of the waves of progress. The establishment in these very days of the Rockefeller Institute of Medical Research is of special significance as an indication that private wealth is about to become the patron of scientific medicine to a degree heretofore unrealized. Let us hope that the future productive scholarship in pathologic and cognate fields in our country may find suitable opportunity for expression in the proceedings of this section in which we trust the pervading atmosphere may be scholarly throughout.

Original Articles.

EFFECT OF DIRECT, ALTERNATING, TESLA CURRENTS AND X-RAYS ON BACTERIA.*

F. ROBERT ZEIT, M.D.

Professor of Clinical Pathology and Bacteriology at the Northwestern University Medical School, and Post-Graduate Medical School.

CHICAGO.

The subject of this study is one that does not seem to have received the attention it merits. The most extravagant claims for and against the effect of various electrical currents have been made in the past. If we are to judge from the vague statements in the current text-books on bacteriology and electro-therapeutics, it becomes evident that further investigation and experimental work are necessary for a more exact knowledge of this interesting and practical subject. I have carefully examined most of the text-books on bacteriology and electro-therapeutics and find but few which mention the subject at all.

On the other hand, we find in the literature numerous cases where the germicidal action of various electric currents seems to have been clinically proven, and where "electricity" is claimed to have cured certain cases. Are these cures only due to the production of antiseptics and germicides by electrolysis? Can any of the various electric currents have any bactericidal or antitoxic properties without electrolysis or heat? Can any tissue changes be caused without electrolysis or heat by electric currents which may cause the death of the bacteria?

How does a magnetic field affect bacteria? What effect have Röntgen rays upon bacteria?

These questions are of the greatest importance in the practical applications of electro-therapeutics in certain infectious conditions. If the effect is a purely chemical one and the current only produces antiseptics by electrolysis, we might as well use these in many cases directly without the current. The same might be said of the physical effects of various currents—heat.

This electrolyitic process of sterilization was employed by Hermite and Webster for sterilization of sewage in 1894, making use of Watt's observation,[1] of 1859, that solutions of magnesium chlorid are converted into hypochlorite, which remains in solution as hypochlorous acid and produces a deposit of magnesium hydrate. Hermite mixed the sewage with sodium chlorid—sea water—and produced hypochlorite by electrolysis. Webster[4] adds chlorids to sewage and uses iron plates as electrodes. The ferrohydroxid produced by electrolysis might as well be added directly to the sewage. Similar processes have since been devised by Oppermann,[2] Marmier and Abraham,[3] Bergé, Hagen and Woolf.

EFFECT OF CONTINUOUS OR DIRECT CURRENT.

Cohn and Mendelssohn[5] in 1879 report that in their experiments the alternating current had no effect, whereas the continuous current caused rapid multiplication of bacteria.

Apostoli[6] studied the antiseptic action of electric currents in 1885, and in 1890 he, together with Laguerriere,[7] reported the results of their experiments to the Paris Academy. Numerous animal experiments were made with bouillon cultures, which were kept at a low temperature by ice. When the current employed was less than 50 milliamperes the virulence of the bacteria was increased at the positive pole only; 300 milliamperes killed anthrax bacilli in five minutes at the positive pole,[6] and 100 to 150 milliamperes were already bactericidal for bacteria without spores.

Prochownik[8] in 1890 treated acute gonorrhea in the female by placing a copper electrode—positive pole—into the cervix and allowing a current of 80 to 100 milliamperes to flow for ten minutes. After three treatments all gonococci had disappeared from the discharge.

Prochownik and Spaeth[9] in 1890 were unable to destroy bacteria by simply dipping the electrodes into the culture medium. They were successful by employing copper electrodes covered with agar and dipped into sodium chlorid solution. Staphylococci and streptococci were killed in fifteen minutes at the positive pole by a current of 60 to 80 milliamperes. Anthrax bacilli with spores required 200 to 230 milliamperes for from one-half to one hour. They attribute the result to the liberation of chlorin.

Verhoogen[10] in 1891 found that the continuous current can only destroy bacteria by chemical or physical effects. If the medium can undergo electrolysis the bacteria die by germicidal acids produced at the positive pole and alkalies at the negative pole. Hydrogen *in statu nascendi* also injures aërobe bacteria at the negative pole. If the medium can not undergo electrolysis the death of bacteria is due purely to physical effects (heat).

Charrin[11] in 1892 dipped copper electrodes into potassium iodid solution and into serum which contained bacilli pyocyanei. A current of 37 to 40 milliamperes destroyed the pigment formation in seven minutes. Longer application of the current destroyed the bacteria by producing iodic acid in the potassium iodid solution and chlorate of copper in the serum.

Kruger[12] in 1893 tried to exclude the chemical and physical effects of continuous currents. By the advice of DuBois-Reymond he employed a method of non-polarizing electrodes, which consists of amalgamated zinc plates in a solution of sulphate of zinc. If a current is allowed to pass through this cell for some time and the current is then suddenly broken, applying the wires leading from the amalgamated zinc plates to a sensitive galvanometer, no deflection of the needle in an opposite direction takes place, which is always the case when other metals or solutions are employed.

Kruger used two glass tumblers filled with zinc sulphate solution, each tumbler containing an amalgamated zinc plate electrode. The bacterial culture was contained in an U-tube of 2 cm. diameter, closed at both ends by a membrane, through which the current had to pass when the two tumblers were connected by the inverted U-tube. The current of 30 Siemens cells was passed through this apparatus, producing an initial current of 80 milliamperes, which rapidly fell to and remained at about 20 milliamperes. If the U-tube contained three days' old bouillon cultures of bacillus pyocyaneus, bacillus prodigiosus or vibrio choleræ Asiaticæ a heavy precipitate of albumin (?) resulted, but the bacteria were not killed after passing the same current for 72 hours through the apparatus. He concludes that the current itself may prevent growth, although it may not kill bacteria. When electrolysis is allowed to take place by passing the current directly through the culture medium he found that any strength of current will destroy bacteria if it is of the proper density and employed long enough. By a current of 20 milliamperes for 24

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. W. T. Howard, D. E. Salmon and W. G. Spiller.

hours he was able to kill the pneumococcus, bacillus murisepticus, bacillus tuberculosis and spore-bearing anthrax and tetanus bacilli. He attributes this result to a combined effect of the current as such and the effect of the ions, the formation of chlorin at the positive pole and its combinations with oxygen, like hypochlorous acid. He found that pure cultures of the pneumococcus and vibrio choleræ Asiaticæ could be employed for immunization after sufficient electrolytic effects of continuous currents.

Smirnow[13] in 1895 claimed that electrolysis of a diphtheria culture changes the toxin into antitoxin when the acidity at the positive pole has reached 0.9 to 1.9, which possesses the same properties as the serum of the im-

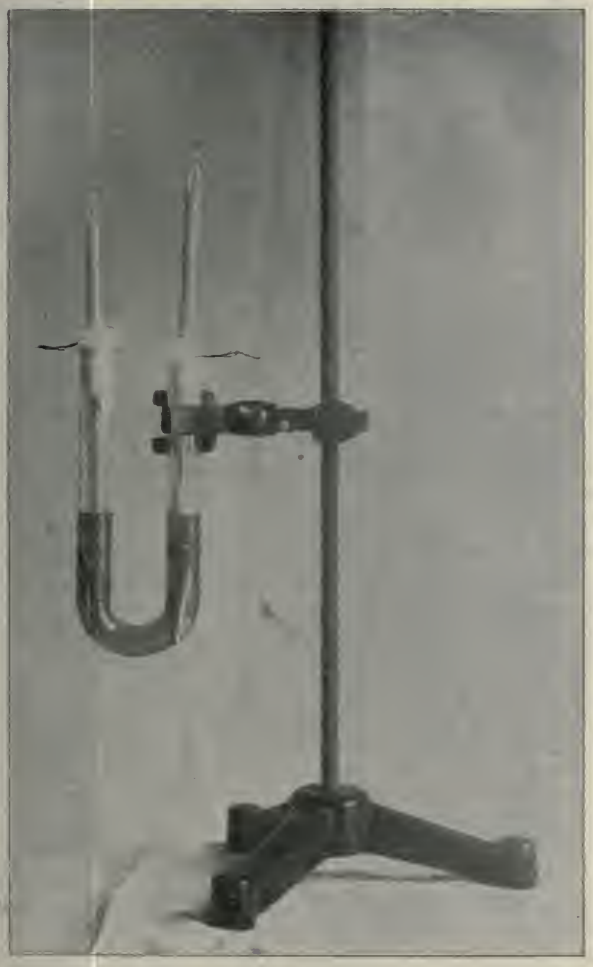

Fig. 1.—Effect of continuous currents on bacteria. Electrolysis and heat. U-tube culture with platinum electrodes.

mune horse. These experiments were repeated and the results verified by Kruger.[14]

Friedenthal[15] in a critical review of the literature of the subject up to 1896 concludes that electrolysis and heat alone destroy bacteria. Electricity acts likes light, which also destroys bacteria only by the formation of antiseptic substances.

Experiments.—Of the numerous experiments I made to determine the part which the continuous electric current plays in the destruction of bacteria, I will give here only a few of the most representative ones, to illustrate the physical effects of the current—heat—and the chemical effect—electrolysis—and the results when both of these factors are reduced to a minimum. In most of the experiments for studying the physical and chemical effects of the current, fresh bouillon cultures were used in glass tubes of a diameter of 16 mm., bent in the form of an U, of a height of 150 mm., and 42 mm. from center to center, supplied with platinum leaf electrodes 10 mm. by 50 mm., attached to platinum wires, as shown in photograph (Fig. 1). Each arm of the U-tube was supplied with a thermometer, to the mercury bulbs of which the platinum leaf electrodes were fastened by thin rubber bands.

Effect of High Temperatures Produced by the Current.—A twenty-four-hour bouillon culture (Fig. 1) of the bacillus pyocyaneus lost its green color entirely within 4 minutes, when a current of 260 to 320 milliamperes was allowed to pass through it. After 10 minutes it looked like clear bouillon and cultures taken from the fluid remained sterile.

Time.	Current.	Temp.	
	260 milliamperes.	23 C.	
2 min.....	280 "	35.5 C.	(Green color fades gradually.)
4 min.....	320 "	62 C.	(Green color disappeared.)
6 min.....	326 "	81 C.	

I had to interrupt the experiment here for 22 minutes because the foam in the arm with the positive electrode filled up to the cotton stopper, and pressed the bouillon up in the other arm to twice the level of the bouillon in the positive arm. When the current was started again it was:

	Current.	Temp.
	280 milliamperes.	65 C.
8 min.....	310 "	80.5 C.
10 min.....	320 "	98.5 C.

The positive arm was filled entirely with foam, the negative arm about three-fourths. The bouillon was clear and stood at a much higher level in the negative arm than in the positive one. Bouillon tubes were inoculated and agar plates poured from the contents of the U-tube, but remained sterile after 24 hours in the incubator.

A control U-tube, containing a bouillon culture of bacillus pyocyaneus was then treated to the same current for 10 minutes. The temperature was kept between 9 and 18 C. by immersing the U-tube in a dish with ice water. Cultures taken from both arms of this tube showed good growth. The same current was then passed for 10 minutes through another control tube which contained only bouillon. After this had cooled down to the temperature of the room it was inoculated with bacillus pyocyaneus and incubated for 24 hours, showing a fair growth at the end of this time.

The death of the bacillus pyocyaneus in the first experiment is plainly due to the physical effects of the current, that is, the production of heat. Bacillus anthracis and bacillus subtilis were not killed when exposed to the same current for the same length of time, because their thermal death point is higher than that produced by this current, whereas the thermal death point of bacillus pyocyaneus, as determined by Sternberg, is 56 C.

Effect of Electrolysis at Low Temperatures.—To determine the chemical effects of the current by electrolysis and the resulting bactericidal products, it was necessary to exclude the effect of heat.

The following experiments illustrate how the variations in time and current result in variations of antiseptic or bactericidal properties of electrolytic products in the culture. All heat effects are excluded. A current of 48 milliamperes for 3 hours has no bactericidal effect.

The electrolytic products are antiseptic but not germicidal. With a current of 100 milliamperes they become bactericidal to non-resistant forms of bacteria in 75 minutes and to anthrax spores in 2 hours. The same current for 3 hours had only an antiseptic effect upon subtilis spores.

1. Anthrax (Spore-bearing); 48 Milliamperes for Two Hours.

Time.	Current.	Temp.	Cultures.
	48.5 milliamperes.	28 C.	
15 min.....	50.5 "	33.7 C.	Good growth.
30 min.....	51.5 "	36 C.	Good growth.
45 min.....	49.5 "	36.7 C.	Fair growth.
	Experiment interrupted.		
Time.	Current.	Temp.	Cultures.
60 min.....	48 milliamperes.	23.4 C.	Poor growth.
75 min.....	46.5 "	26.5 C.	Poor growth.
90 min.....	47.5 "	30 C.	Very few colonies.
105 min.....	48 "	31.7 C.	Very few colonies.
120 min.....	48 "	32.8 C.	Very few colonies.

The current was interrupted for 5 minutes to take cultures between each reading. At the end of the experiment the bouillon looked perfectly clear. Ten loopsful plated out in agar gave four colonies. A control tube

Fig. 2.—Effect of continuous current on bacteria. Electrolysis and low temperature. Four U-tube cultures with platinum electrodes, in series.

of bouillon treated in the same manner and inoculated with bacillus anthracis showed no growth after one night in the incubator, but when plated out many colonies grew upon the agar, showing that the electrolytic products were antiseptic but not bactericidal.

2. Staphylococcus Pyogenes Aureus and Albus, 48 Milliamperes, for Three Hours.

Time.	Current.	Temp.	Cultures.
	48 milliamperes.	27 C.	
15 min.....	48.5 "	33 C.	Good growth.
30 min.....	48 "	34 C.	Good growth.
45 min.....	48 "	32 C.	Fair growth.
60 min.....	48 "	30.2 C.	Fair growth.
75 min.....	48 "	31.8 C.	Very good growth.
90 min.....	48 "	32.3 C.	Very good growth.
105 min.....	48 "	31.3 C.	Very good growth.
120 min.....	48 "	32 C.	Fair growth.
140 min.....	48 "	32 C.	Good growth.
180 min.....	47 "	31 C.	Good growth.

A control tube of bouillon through which a current of 48 milliamperes was passed for 3 hours was inoculated with staphylococcus albus and showed no growth after one night in the incubator, but when plated out many colonies grew.

3. Bacilli Pyocyaneus, Typhosus, Anthracis and Subtilis.—With 100 milliamperes for 75 minutes, the temperature rose to 38 degrees C. in 20 minutes, so I resorted to cooling by ice water. The current was passed in series through the four U-tubes, which had been placed in glass tumblers containing ice water, as in photograph (Fig. 2).

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
	100 milliamperes.	10 C.	6 C.
15 min.....	115 "	7.5 C.	4 C.
30 min.....	100 "	9 C.	6 C.
45 min.....	100 "	10 C.	5 C.
60 min.....	100 "	10 C.	10 C.
75 min.....	100 "	7 C.	5 C.

Agar plates were made of all tubes after 75 minutes, and incubated over night. The pyocyaneus and typhoid plate showed no growth, anthrax six small colonies and subtilis showed many well-growing colonies. Control tubes inoculated showed no growth with any of the four bacteria, but when plated out anthrax and subtilis plates showed many colonies.

4. Bacilli Pyocyaneus, Typhosus, Anthracis and Subtilis.—With 100 milliamperes for 120 minutes. The arrangement was the same as in the last experiment.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
	100 milliamperes.	9 C.	6 C.
30 min.....	100 "	10 C.	5 C.
60 min.....	100 "	10 C.	10 C.
90 min.....	100 "	3 C.	3 C.
105 min.....	110 "	8 C.	7 C.
120 min.....	100 "	7 C.	5 C.

Agar plates made of pyocyaneus, typhoid and anthrax tubes remained sterile, that of subtilis tube showed a fair number of well-growing colonies.

Control tubes through which a current of 100 milliamperes had been passed for 2 hours, showed no growth when inoculated with any of the four bacteria and incubated. Plates made from these control tubes remained sterile except the bacillus subtilis plate, which showed many colonies.

5. Bacilli Pyocyaneus, Typhosus, Anthracis and Subtilis.—With 100 milliamperes for 180 minutes.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
	100 milliamperes.	9 C.	6.5 C.
60 min.....	100 "	3 C.	3 C.
120 min.....	110 "	7 C.	7 C.
140 min.....	100 "	4 C.	4 C.
160 min.....	110 "	9 C.	6 C.
180 min.....	100 "	6 C.	6 C.

Pyocyaneus, typhoid and anthrax plates remained sterile, subtilis plates showed many well-growing colonies.

6. Staphylococcus Aureus, Bacilli Pyocyaneus, Prodigiosus and Anthracis.—With 130 to 150 milliamperes for 80 minutes.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
	125 milliamperes.	21 C.	20 C.
5 min.....	130 "	32 C.	27 C.
10 min.....	140 "	31.5 C.	30.5 C.

The prodigiosus culture became decolorized at the negative pole, and the pyocyaneus culture turned brown at the positive pole.

The current was interrupted after 10 minutes until the temperature of the cultures had fallen again.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
		23 C.	21 C.
20 min.....	130 milliamperes.	38 C.	30 C.

The temperatures again rose rapidly, so I had to interrupt current again for cooling. The foam collecting

upon the bouillon at the negative pole was red in the prodigiosus tube and green in the pyocyaneus tube, the bouillon in both tubes being decolorized.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
		23 C.	23 C.
30 min..	130-140 milliamperes.	37 C.	30 C.

All the U-tubes were now placed into tumblers with ice water to prevent the rapidly rising temperatures.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
		8 C.	8 C.
40 min.....	120 milliamperes.	12 C.	8 C.
60 min.....	130 "	11 C.	11 C.
70 min.....	130 "	12 C.	12 C.
80 min.....	130 "	15 C.	12 C.

All the tubes were now plated out with agar and remained sterile, except a few colonies on the anthrax plate, after 24 hours' incubation.

7. Staphylococcus Aureus, Bacilli Pyocyaneus, Prodigiosus and Anthracis.—With 130 to 150 milliamperes for 180 minutes.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
		6 C.	4 C.
30 min.....	130 milliamperes.	12 C.	8 C.
60 min.....	135 "	11 C.	11 C.
90 min.....	140 "	11 C.	10 C.
120 min.....	150 "	12 C.	11 C.
150 min.....	140 "	16 C.	19 C.
180 min.....	130 "	10 C.	8 C.

All the tubes were plated out on agar and remained sterile in incubator.

Control tubes through which the same current was passed for 3 hours had a strong odor of hypochlorous acid, and showed no growth when inoculated with the above bacteria. When these were plated out no growth took place.

Germicidal Substances at Positive and Negative Pole.—A series of experiments was now made to determine as far as possible the effect of the different bactericidal substances produced by electrolysis at the positive and negative pole in the culture. Museum jars having an inside diameter of 42 mm. and 130 mm. high were filled one-half with bouillon. An inverted U-tube was then made to connect the two jars, and the bouillon was drawn into the U-tube by a small rubber tube which was withdrawn when the bouillon arch was formed, without any air bubbles. Into each jar was placed a thermometer with platinum leaf electrode, 10 by 50 mm., which was fastened to the mercury bulb of the thermometer by a thin rubber band. The jars were then stoppered with cotton and the whole apparatus, which is shown in photograph, sterilized (Fig. 3).

The two jars were inoculated with spore-bearing anthrax bacilli and incubated at 37 C. for 24 hours.

Time.	Current.	Temperature. Pos. Pole.	Neg. Pole.
	95 milliamperes.	19 C.	19 C.
15 min.....105	"	27 C.	25 C.

To prevent the rapidly-rising temperature at the two poles, the whole apparatus was placed into a potato dish containing water and ice, as illustrated by photograph, and the experiment continued (Fig. 4).

Time. Minutes.	Current. Milliamperes.	Temperature. Pos. Pole.	Neg. Pole.	Cultures. Pos. Pole.	Neg. Pole.
30	100	15 C.	15 C.	Good growth.	Good growth.
40	95	7.5 C.	7.5 C.	. . . . .	. . . . .
50	100	9 C.	9 C.	. . . . .	. . . . .
60	100	13 C.	14 C.	Few colonies.	Many colonies,
90	105	19 C.	17 C.	2 "	26 "
120	100	18 C.	18 C.	No growth.	No growth.

The culture fluid had a strong acid reaction at the positive pole and an odor of hypochlorous acid.

At the negative pole the reaction was strongly alkaline, requiring 8.82 milligrams of H_2SO_4 to neutralize 1 c.c. of the culture fluid.

The two cultures were shaken and plated out in agar, but no growth resulted from either jar. After 24 hours I again made plates which also remained sterile.

A control experiment was made by passing 100 milliamperes through three similar contrivances for 2 hours, at 31 to 36 C., after which the bouillon was inoculated with bacilli prodigiosus, pyocyaneus and anthracis and placed in the incubator.

All remained sterile, and, when I plated them out, no growth took place, showing that the germicidal substances produced in the bouillon by electrolysis were sufficient at both poles to kill these bacteria.

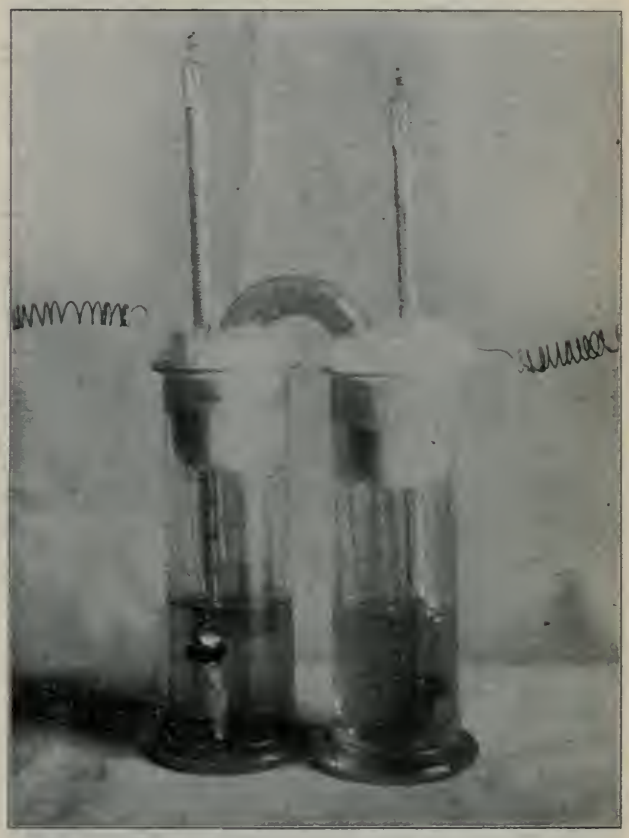

Fig. 3.—Effect of continuous current on bacteria. Germicidal substances produced at positive and negative poles. Culture jars connected by U-tube arch of bouillon. Platinum electrodes.

The bacillus subtilis in a former experiment had shown such marked resistance to the electrolytic bactericidal products of the current that I employed it here also to determine the effects of electrolytic products at the two poles. In a former experiment I was unable to kill the bacillus subtilis by a current of 100 milliamperes for 3 hours. Now I found that the bacillus subtilis was dead at the positive pole in 2 hours, whereas at the negative pole living bacilli or rather spores were still present after the current had passed 4 hours. The earlier death at the positive pole of anthrax and subtilis spores is due to the liberation of chlorin, which combines with oxygen to form hypochlorous acid.

At the negative pole, sodium in the presence of water, forms sodium hydroxid and liberates nascent hydrogen, which rises in numerous bubbles. These bactericidal

products of electrolysis are only present in the two jars. The bouillon arch is practically free from them.

Effect of Continuous Current Without Heat and Electrolysis.—Friedenthal[15] in his critical review of Kruger's[12] work in this direction, has already pointed out that it is illogical to attempt to prevent the influence of heat by cooling and the effect of electrolysis by the use of non-polarizing electrodes, because, if we eliminate both these factors, every influence of electricity is removed.

Kruger[12] maintains that the continuous current alone by means of non-polarizing electrodes and exclusion of chemical effects by ions, is capable of preventing completely the growth of bacteria without necessarily killing them.

I have carefully repeated his experiments with bacillus pyocyaneus, using two glass tumblers 54 mm. wide by 100 mm. high inside diameter, containing a strong solution of zinc sulphate. Each tumbler was supplied with a zinc plate electrode, 40 mm. wide as in the photograph. These electrodes were amalgamated in the usual way by sulphuric acid and mercury. An U-tube of 16 mm. inside diameter, 150 mm. high and 42 mm. from center to center, was filled with bouillon, both openings being closed by tying animal membrane over them. The tubes were sterilized and inoculated with enough of a fresh bouillon culture of bacillus pyocyaneus to give it a faint greenish color. The membranes were again tied and the tube placed in the two tumblers containing zinc sulphate solution with thermometers (Fig. 5).

Fig. 4.—Effect of continuous current on bacteria. Germicidal substances at positive and negative poles, with cooling apparatus.

Time.	Current. Milliamperes.	Temperature. Pos. Pole.	Temperature. Neg. Pole.	Remarks.

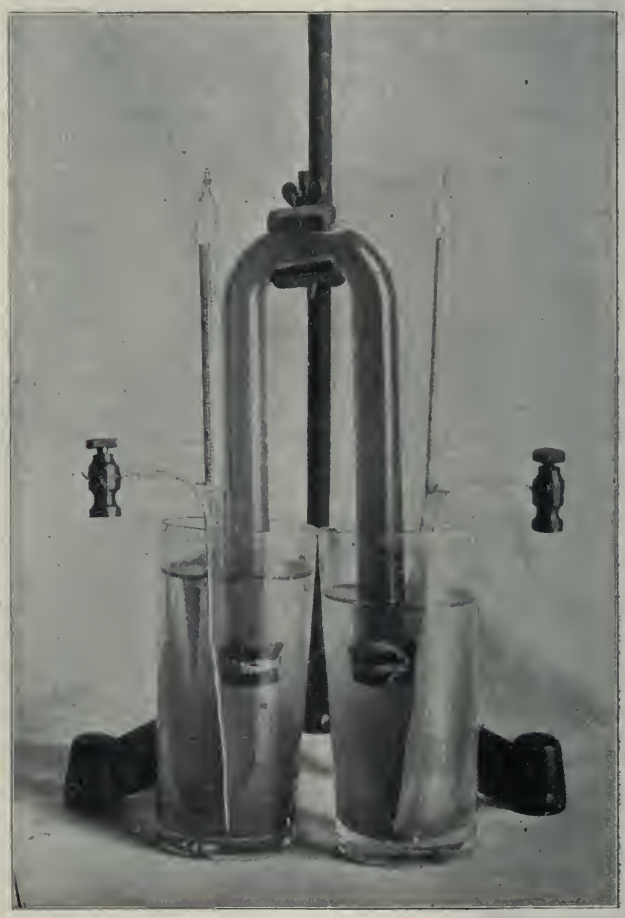

Fig. 5.—Effect of continuous currents. Du Bois-Reymond non-polarizing electrodes in zinc sulphate solution. Culture in U-tube closed by animal membranes. Exclusion of heat and electrolysis.

The reaction of the zinc sulphate solution remained acid in both tumblers during the whole experiment. The current as given represents the results of passing the regular 110-volt Edison current directly through the apparatus without any other resistance in series. The resistance of the apparatus, therefore, must have been between 1100 ohms (100 milliamperes) and 3440 ohms (32 milliamperes).

The turbidity gradually passing from the positive pole to the negative is due to electric osmose. When a current is sent through two different fluids which are separated by an animal membrane the liquid at the positive pole passes through this membrane towards the negative pole.

After the experiment was completed the U-tube was incubated for 12 hours and showed no growth, but neither did a control tube to which I had added enough zinc

sulphate solution to cause a similar turbidity. Both tubes when plated out on agar showed fair growth. It would appear from this that electric osmose of zinc sulphate solutions through the porous membrane was alone sufficient to prevent growth.

Such an arrangement of apparatus like the one used will not exclude the production of small quantities of antiseptic substances at the electrodes. Electric osmose causes such a turbidity of the bouillon, gradually passing from the positive to the negative pole, that we must also consider the deterioration of the culture medium in this experiment. I have passed the same current through another U-tube with bouillon for the same length of

Fig. 6.—Effect of a magnetic field on bacteria. Culture within helix of 900 turns of wire. For currents of ½ to 3 amperes—1350 to 2700 ampere turns.

time (24 hours) and then inoculated the turbid bouillon with a similar quantity of a fresh pyocyaneus culture and found no growth after incubation.

All this goes to prove that the continuous current itself is not bactericidal, nor even antiseptic, but that it can destroy bacteria only by heat or the production of bactericidal substances by electrolysis.

EFFECT OF A MAGNETIC FIELD ON BACTERIA.

A most remarkable contribution was made in 1891 by Spilker and Gottstein.[16] They claimed to have discovered that a strong continuous current, made to pass through a spiral coil of wire wound around a test tube containing a watery suspension of bacteria, will kill these. They distributed a few loopfuls of a fresh agar culture of the bacillus prodigiosus in sterile water, contained in a test tube of 250 c.c. and passed a current of 2½ amperes through this helix of wire around the tube, for 24 hours. The bacillus prodigiosus was said to have been killed. They then added a little nutritive gelatin to the water and found the same result. Stronger currents were effective in a shorter time, as follows: 5 amperes in 21 to 22 hours; 10 amperes in 4 hours, and 12.5 amperes in 80 minutes. They concluded that micro-organisms can be killed by the induction-electricity (?). When they added ferrum albuminatum to the suspension of bacteria—1 to 1000—they were able to kill the bacillus prodigiosus in from 5 to 30 minutes by a current of 12½ amperes passing through the helix.

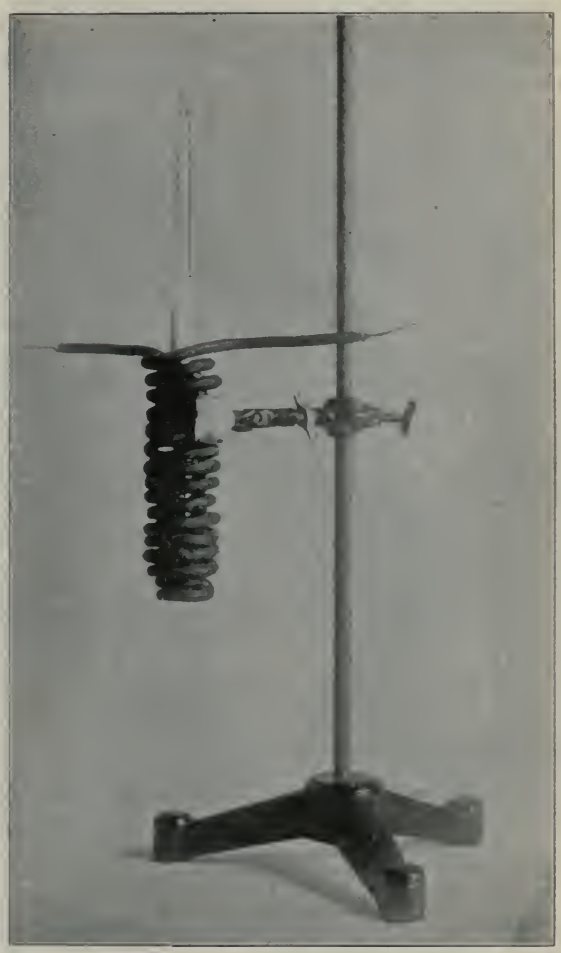

Fig. 7.—Effect of a magnetic field on bacteria. Culture within helix of 15 turns of wire. For currents of 12 amperes—360 ampere turns.

Kruger[12] and Friedenthal[18] repeated these experiments. Kruger thought the effect was negative or at least very slight. Friedenthal had only negative results.

Thiele and Wolf[17] used a solenoid 10 cm. long, consisting of seven layers of forty-four turns each, of a wire 2 mm. thick. A current of 7½ amperes (2310 ampere turns) for 8 hours had no effect whatever.

EXPERIMENTS.—I used a helix of wire 125 mm. long, outside diameter 70 mm., inside diameter 18 mm., with twelve layers of seventy-five turns each of No. 16 (B. and S. gauge) double cotton covered wire, that is, 900 turns of wire. The inside diameter is just large enough to

admit a common size test tube. The tubes were filled about three-quarters full with hydrant water, a thermometer was inserted and they were then sterilized as usual. Suspensions of the bacilli prodigiosus and pyocyaneus were made by stirring enough of a fresh agar culture into the sterile water to color it slightly.

a.—A tube with a suspension of bacillus prodigiosus was placed in the helix (Fig. 6) and a current of 3 amperes (2700 ampere turns) passed through it.

Time.	Temp.	Culture.
	19 C.	Good growth.
½ hour.....	41 C.	" "
1 hour.....	49 C.	" "
1½ hours.....	64 C.	" "
2 hours.....	65 C.	Fair growth.
3 hours.....	67.5 C.	Poor growth.
4 hours.....	68.5 C.	No growth.

The fluid was plated out on agar. No growth. Control tube showed good growth. The result here is evidently due to heat. Practically the same results were found with suspensions of bacillus pyocyaneus.

b.—The same experiment was repeated except that a current of only 1½ amperes was allowed to flow through

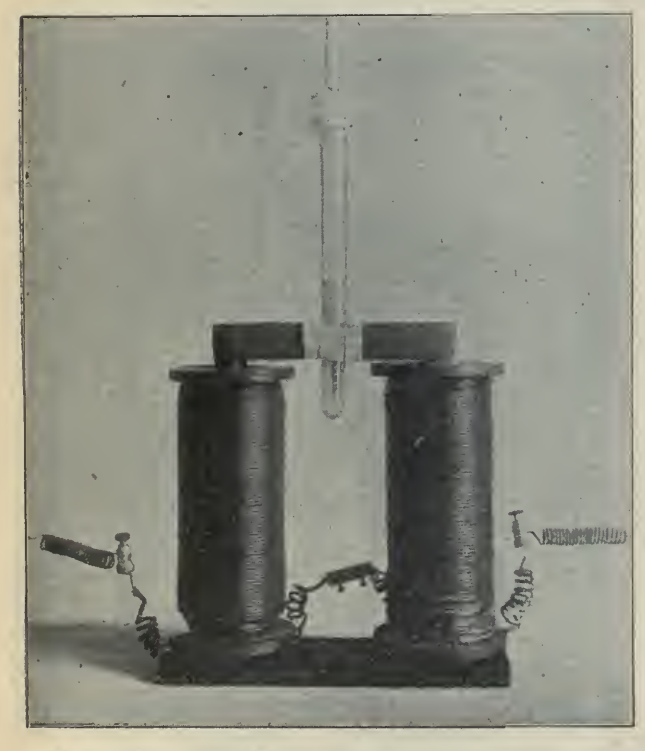

Fig. 8.—Effect of a magnetic field on bacteria. Culture between the poles of a powerful electro-magnet.

the 900 turns of wire of the helix (1350 ampere turns) to maintain a low temperature.

c.—A few experiments were made also with a solenoid consisting of two layers of fifteen turns each of a very heavy, double rubber coated electric light wire (No. 12 B. and S. gauge) wound tightly around a test tube containing bacillus pyocyaneus (Fig. 7). The current used was 12 amperes (360 ampere turns) for 40 hours in both cases. The temperature ranged between 20 and 26 and a comparison with control tubes and plates after this time displayed no difference whatever. The same was true of the bacillus prodigiosus.

It is evident from this that Spilker and Gottstein's results must have been due to heat, because exhaustion of fluid and starvation of bacteria was prevented in their experiments by the addition of a small quantity of gelatin. Whenever I did this or added ferrum albuminatum. the prodigiosus grew markedly in the suspension during the long time of exposure to the current.

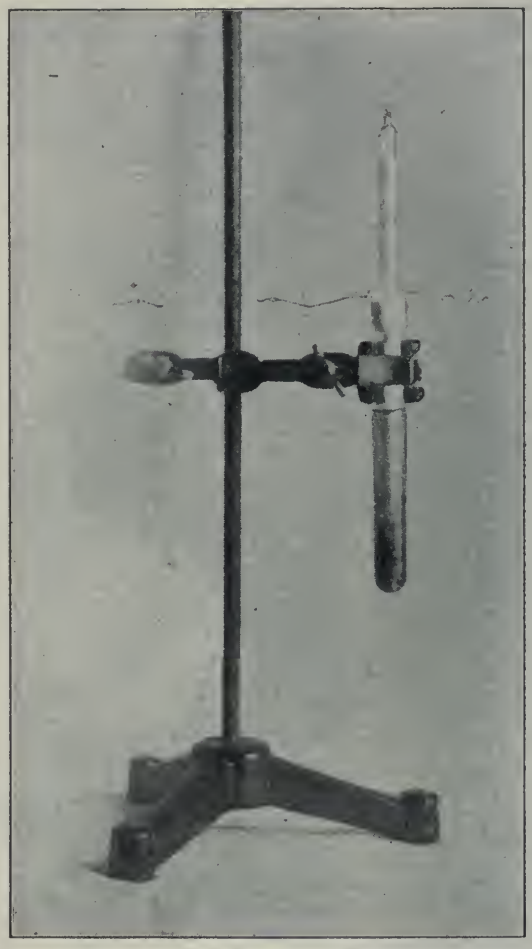

Fig. 9.—Effect of alternating currents on bacteria. Culture tube with platinum electrodes.

How they can speak of induction electricity here I can not understand. The bacterial culture is simply in the magnetic field of the helix of wire.

d.—Therefore, I have made a few more experiments to determine if a strong magnetic field may have any influence on the bacillus prodigiosus and pyocyaneus. A powerful electro-magnet with a coil of 900 turns of wire on each core (20 by 180 mm.), with two pole pieces approaching each other so as to hold the watery suspension of bacteria in a test tube, was energized by a current of 1 ampere (1800 ampere turns) for 200 hours, the temperature ranging between 20 and 28 C. When these were plated out they showed better growth than the control tube. The test-tubes were held between the poles of the magnet by cork (Fig. 8).

Finally I placed similar suspensions between the poles

of a powerful 110-volt Crocker-Wheeler dynamo for 4 days, and, if the temperature was kept below 30 C., the growth in the tubes agreed closely with control tubes.

EFFECT OF ALTERNATING CURRENTS ON BACTERIA.

Cohn and Mendelssohn[5] in 1879 report negative results with alternating currents.

In 1896 Marmier[19] reports that alternating currents of low frequency destroy bacterial toxins by the production of hypochlorites and chlorin.

The same year, Lortet[20] discovered that motile bacteria place themselves in parallel rows to the current. The current does not kill them except when antiseptic substances have been produced.

Heller[21] in 1897 reported that he was able to destroy bacteria by means of the alternating current obtained from the secondary of an induction coil, the primary of which received a current of 5 Bunsen cells. Bacteria were dead in 30 minutes, whereas mucor spores remained alive.

EXPERIMENTS.—An ordinary test-tube containing a fresh bouillon culture of the bacillus prodigiosus was supplied with a thick thermometer, to the mercury bulb of which were fastened two platinum electrodes, 10 by 50 mm., by a thin rubber band (Fig. 9). I passed the secondary current of a three-inch spark, Ruhmkorff coil, through this apparatus for 10 hours, taking cultures

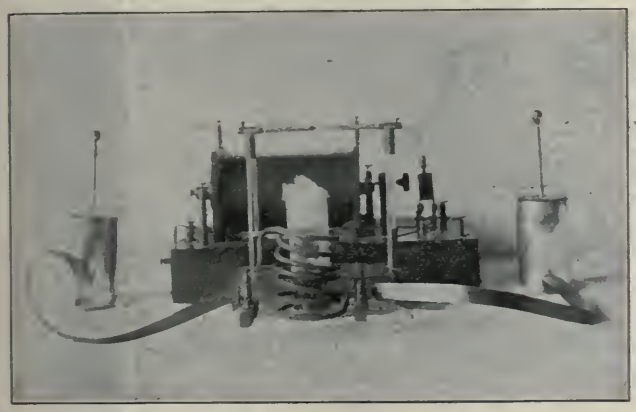

Fig. 10.—High frequency alternating currents.

every hour, with the result that the tubes inoculated grew better and better the longer the current passed, and developed a most beautiful pigment production.

A similar experiment was made with the apparatus shown in Fig. 3, with a three-day-old bouillon culture of bacillus pyocyaneus. The secondary of an eight-inch spark coil was employed, but the growth of bacteria and the pigment production was rather favored than hindered by the current.

The Lortet experiment was also repeated several times by means of a glass slide upon which a square coil was built by means of paraffin. The two platinum electrodes were fastened by paraffin to the slide, their ends protruding into the paraffin cell. The cell was filled with a suspension of typhoid bacilli in sterile water. The results were identical with those of Lortet, but early formation of gas bubbles does not allow of any extended examination. When the current was interrupted the bacilli showed the normal motility.

EFFECTS OF TESLA CURRENTS OR CURRENTS OF HIGH POTENTIAL AND HIGH FREQUENCY.

D'Arsonval and Charrin[22] in 1893 were the first to study the effects of high frequency currents on bacteria. A culture of the bacillus pyocyaneus was placed into a solenoid through which an alternating current of 800,000 oscillations per second was passed for 60 minutes. The green color of the culture disappeared.

The same authors in 1896[23] made numerous animal experiments with cobras, which were injected by virulent cultures of bacilli diphtheriæ and pyocyanei after the cultures had been treated with high frequency currents. They concluded that high frequency currents attenuated the toxins which could then be used for immunization by injection.

Marmier[24] repeated the experiments and was unable to detect any attenuation of toxins.

Bonome and Viola[25 26] found that high potential alternating currents decrease the virulence of streptococcus cultures, one to four days old, and make cultures 20 to 30 days old non-virulent, although the streptococci are not killed. The current only acts on the toxins, which are changed into antitoxins by high potential currents. The cultures were placed into U-tubes with platinum electrodes. The current was taken from a Tesla coil, through which the secondary current of a Ruhmkorff coil was passed.

Dubois[27] concludes that experiments with rabbits demonstrate the destructive action of high potential currents upon the vitality and virulence of streptococci.

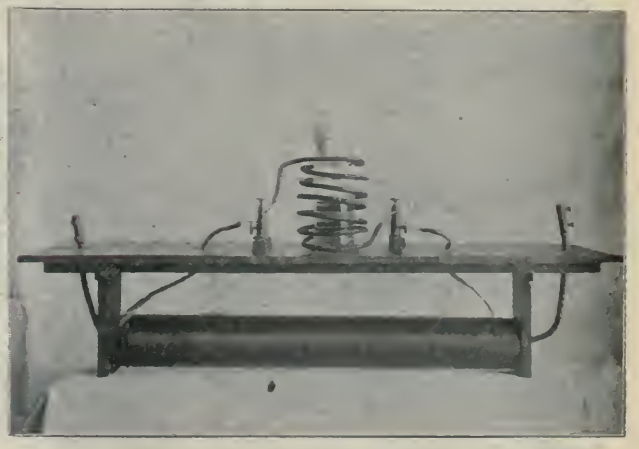

Fig. 11.—Tesla coil. Culture jar within secondary solenoid The Tesla coil is immersed in boiled linseed oil for the experiment

Oudin[28] contends that Tesla currents are germicidal and antitoxic, as demonstrated by cures of lupus molluscum contagiosum and healing of large ulcers by simple local action without burns or injury to the epidermis. These currents represent a new form of transformation of electricity into light.

Krause[29] believes that the decolorization of the pyocyaneus and prodigiosus cultures within a solenoid is probably due to the formation of ozone and slight electrolytic changes in the culture medium, because these bacteria produce their usual pigments again when transplanted.

EXPERIMENTS.—*a*.—High frequency alternating currents. The secondary of a three-inch Ruhmkorff coil was connected to the inner coating of two Leyden jars, 70x160 mm., with a Hertz spark gap between zinc points of 10 mm. The outer coatings of the Leyden jars were connected to a solenoid consisting of seven turns of thick wire. Into this solenoid I placed a small museum jar, 42x130 mm., with a suspension of bacillus pyocyaneus in bouillon sufficient to give the bouillon a slight greenish tinge (Fig. 10). The rapid oscillatory discharges of the Leyden jars through this solenoid produce high fre-

quency alternating currents in the solenoid, probably many hundred thousand oscillations per second. The effect upon the bacterial suspension was entirely negative. The current was passed with interruptions for 6 hours. All the cultures taken grew well and the greenish color of the bouillon was not changed in the least.

b.—High frequency, high potential currents—Tesla currents. One of the secondary terminals of an eight-inch Ruhmkorff coil was connected to the inner coating of a Leyden jar and to the primary of a Tesla coil. The other secondary terminal was connected to the outer coating of the Leyden jar, and, through a spark gap of zinc points, to the other primary of the Tesla coil. The spark gap was placed between the poles of a powerful electro-magnet, protected by mica plates, to blow out the arc as soon as formed, so that the fundamental discharges occur in quicker succession as suggested by Tesla.[41]

The Tesla coils used consisted of a primary spiral of thick (No. 6 B. and S. gauge, 4 mm.) wire, the individual turns 10 mm. apart from each other and of a diameter of 40 mm. A thick rubber tube (6 mm.) surrounded the primary coil. Upon this rubber tube were wound 200 turns of a wire 1 mm. thick (No. 18 B. and S. gauge), about 1 mm. between each turn. The coil was fastened by rubber support to a board carrying the two primary and secondary terminals as shown in Fig. 11. The whole coil was immersed in boiled linseed oil. The arrangement of the apparatus is shown in Fig. 12.

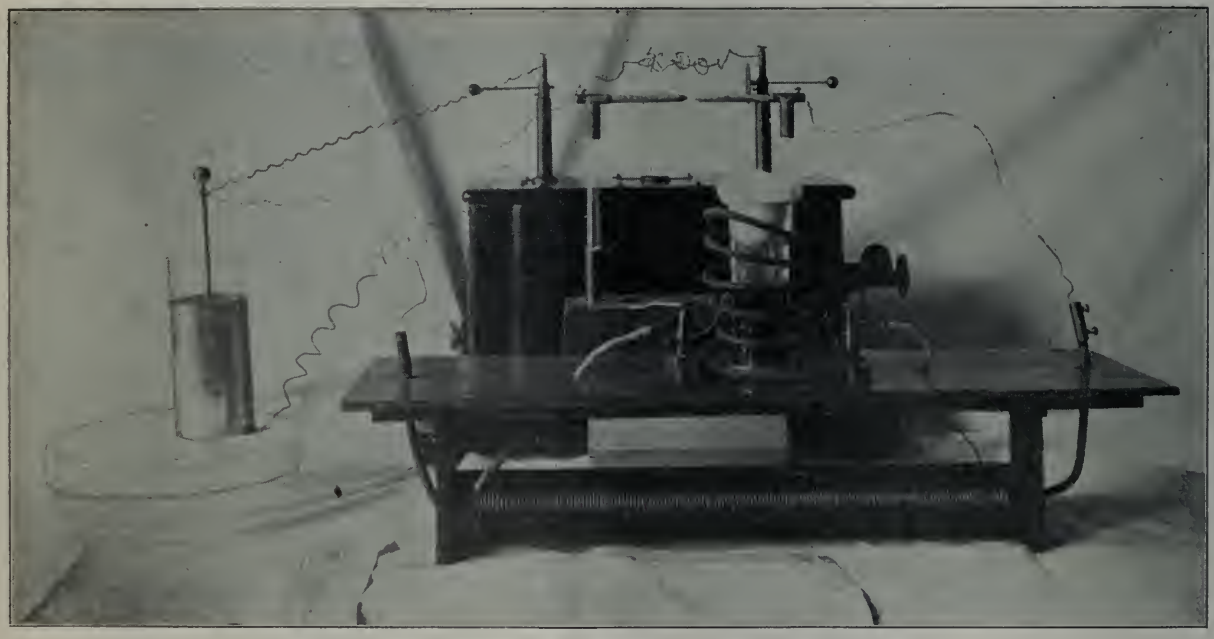

Fig. 12.—High frequency, high potential currents. Tesla currents.

In the former experiment a high frequency current was made to pass through a helix surrounding the bacterial suspension. The primary of the Tesla coil now receives the same current, and induces, in the secondary winding of the Tesla coil, currents of many millions of volts, that is, high potential and high frequency currents. We can draw a shower of sparks from one of the electrodes without any sensations of pain. A suspension of bacillus pyocyaneus was exposed within the same solenoid used in the foregoing experiment, only that it now was connected to the terminals of the secondary winding of the Tesla coil. The current was passed for one hour, and plates made from the bouillon culture in solenoid showed good growth. The same experiment was repeated with bacillus typhosus, coli communis, diphtheriæ, proteus vulgaris, staphylococcus aureus and micrococcus tetragenus, and, in all cases, the agar plates showed good growth.

When the terminals of the Tesla secondary are separated beautiful brush discharges appear. Agar suspensions of bacteria in plates exposed to these show no growth, but the strong odor of ozone betrays the cause of this result.

EFFECT OF ROENTGEN RAYS ON BACTERIA.

Berton[30] exposed bouillon cultures of bacillus diphtheriæ for 16, 32 and 64 hours without any effect upon growth or virulence.

Minck[31] exposed an agar plate which had been inoculated with one loopful of bacillus typhosus and exposed it for 3 hours at a distance of 10 centimeters from the tube. When incubated it showed no difference in growth from a control plate.

Wittlin[32] repeated Minck's experiments with bacillus typhosus, bacillus diphtheriæ, staphylococcus aureus and vibrio choleræ Asiaticæ and concludes that Röntgen rays have no influence upon the growth or life of bacteria.

Blaise and Lambuc[33] experimented with bacillus anthracis and found that 3 hours' exposure had no effect. They explain the favorable clinical results by phagocytosis which may be caused by the rays.

Bergonie and Mongour[34] use Röntgen rays in the treatment of tuberculosis of the lung because they believe phagocytosis is caused. They were unable to reduce the virulence of tubercle bacilli by exposing the sputum to the rays.

Muhsam[35] found that tubercular guinea-pigs were not improved by exposure to Röntgen rays.

Schiff[36] does not believe in any deleterious influence of *x*-rays upon tubercle bacilli in cases of lupus. He believes that the violent inflammation caused in the deeper layers of the skin by the rays are sufficient to produce unfavorable conditions for the growth of bacteria.

Rieder[37] was the first to report germicidal effects of Röntgen rays. He was unable to kill well-grown colonies of bacteria on culture plates. He inoculated agar tubes and plated them out. The open plates were covered

with a lead plate from which a square or circle had been cut out. After a one-hour exposure the plates were covered and placed in the incubator, with the result that the portion of the plate which had been covered by lead showed numerous well-growing colonies, whereas the portion exposed to the rays showed no growth. By various arrangements for control of experiments he excluded heat rays, light rays and electrical effects. He thinks that he can exclude chemical effects, because bacteria inoculated afterwards upon the portion exposed to the rays grow well. These experiments were repeated by others, partially with negative and partially with positive results. Rieder[38] explains the negative results by insufficient intensity of the rays.

Himmel[39] thinks that deeper and more extensive necrosis is produced in lupus than in normal skin.

Levy-Dorn[40] expresses the view that the generally accepted opinion that *x*-rays are bactericidal is wrong. Rieder's experiments were made with rays of great intensity, whereas, in the therapeutic application of the rays, any bactericidal properties of the rays are out of the question. He compares the bactericidal effect of the rays

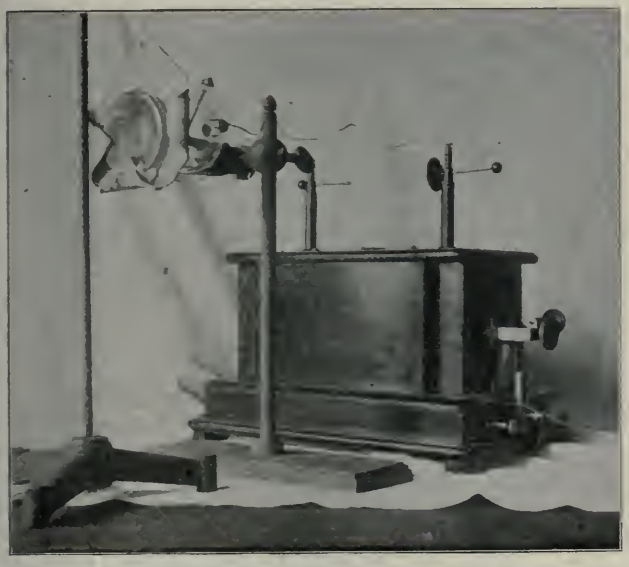

Fig. 13.—Effect of Röntgen rays on bacteria. Open Petri dish with agar culture. Perforated lead plate as cover. Exposed agar film directly to *x*-ray tube.

with that of an attempt to disinfect the intestinal canal with a few drops of creosote, and believes the positive cures of lupus, favus, and psoriasis and chronic eczema by the rays is not due to any direct bactericidal effect.

EXPERIMENTS.—*a*. Bouillon and hydrocele-fluid cultures in test-tubes of bacillus pyocyaneus, prodigiosus, typhosus, anthracis and diphtheriæ were exposed to Röntgen rays at a distance of 2 cm. from the tube for 2, 5, 10, 20 and 48 hours without any effect whatever upon pigment production, growth, motility or virulence.

A repetition of Rieder's experiments proved negative.

b. Suspensions of the same bacteria in agar were plated out. For the glass cover of the plate I substituted a lead plate 5 mm. thick, which had an oval window cut out in the center. The plate was then exposed to the rays, with its agar film towards the tube, at a distance of 20 mm., for ½, 1, 2 and 4 hours (Fig. 13). When incubated the exposed portion of the agar showed just as many colonies as the non-exposed portions.

c. A serum plate was smeared thickly with sputum containing from 50 to 100 tubercle bacilli to the field. The plate was exposed without cover for 6 hours to the rays at a distance of 20 mm. from the tube. Three guinea-pigs were inoculated, of which one died in five weeks and one in seven weeks of acute miliary tuberculosis. One is alive yet, but is tubercular. It has enlarged inguinal glands, constantly elevated temperature and has continually lost in weight.

I conclude from this that Röntgen rays have no direct bactericidal properties. The clinical results must be explained by other factors, possibly the production of ozone, hypochlorous and nitrous acid, extensive necrosis of the deeper layers of the skin, and phagocytosis.

CONCLUSIONS.

1. A continuous current of 260 to 320 milliamperes passed through bouillon cultures kills bacteria of low thermal death points, in 10 minutes by the production of heat—98.5 C. The antiseptics produced by electrolysis during this time are not sufficient to prevent growth of even non-spore bearing bacteria. The effect is a purely physical one.

2. A continuous current of 48 milliamperes passed through bouillon cultures for from 2 to 3 hours does not kill even non-resistant forms of bacteria. The temperature produced by such a current does not rise above 37 C. and the electrolytic products are antiseptic but not germicidal.

3. A continuous current of 100 milliamperes passed through bouillon cultures for 75 minutes kills all non-resistant forms of bacteria even if the temperature is artificially kept below 37 C. The effect is due to the formation of germicidal electrolytic products in the culture. Anthrax spores are killed in 2 hours. Subtilis spores were still alive after the current was passed for 3 hours.

4. A continuous current passed through bouillon cultures of bacteria produces a strongly acid reaction at the positive pole, due to the liberation of chlorin which combines with oxygen to form hypochlorous acid. The strongly alkaline reaction of the bouillon culture at the negative pole is due to the formation of sodium hydroxid and the liberation of hydrogen in gas bubbles. With a current of 100 milliamperes for 2 hours it required 8.82 milligrams of H_2SO_4 to neutralize 1 c.c. of the culture fluid at the negative pole, and all the most resistant forms of bacteria were destroyed at the positive pole, including anthrax and subtilis spores. At the negative pole anthrax spores were killed also, but subtilis spores remained alive for 4 hours.

5. The continuous current alone, by means of DuBois-Reymond's method of non-polarizing electrodes and exclusion of chemical effects by ions in Kruger's sense, is neither bactericidal nor antiseptic. The apparent antiseptic effect on suspension of bacteria is due to electric osmose. The continuous electric current has no bactericidal nor antiseptic properties, but can destroy bacteria only by its physical effects—heat—or chemical effects, the production of bactericidal substances by electrolysis.

6. A magnetic field, either within a helix of wire or between the poles of a powerful electro-magnet, has no antiseptic or bactericidal effects whatever.

7. Alternating currents of a three-inch Ruhmkorff coil passed through bouillon cultures for 10 hours favor growth and pigment production.

8. High frequency, high potential currents—Tesla currents—have neither antiseptic nor bactericidal properties when passed around a bacterial suspension within a solenoid. When exposed to the brush discharges, ozone is produced and kills the bacteria.

9. Bouillon and hydrocele-fluid cultures in test-tubes of non-resistant forms of bacteria could not be killed by

Röntgen rays after 48 hours' exposure at a distance of 20 mm. from the tube.

10. Suspensions of bacteria in agar plates and exposed for 4 hours to the rays, according to Rieder's plan, were not killed.

11. Tubercular sputum exposed to the Röntgen rays for 6 hours at a distance of 20 mm. from the tube, caused acute miliary tuberculosis of all the guinea-pigs inoculated with it.

12. Röntgen rays have no direct bactericidal properties. The clinical results must be explained by other factors, possibly the production of ozone, hypochlorous acid, extensive necrosis of the deeper layers of the skin, and phagocytosis.

LABORATORY OBSERVATIONS ON HYDROPHOBIA IN OHIO.*

A. P. OHLMACHER, M.D.

Professor of Pathology, Northwestern University Medical School.
CHICAGO.

In the past five years several cases of suspected hydrophobia have been brought to my notice from various quarters of the State of Ohio, and I desire to lay before you a condensed account of them.

Case 1.—This case came to my laboratory at the Medical Department of the University of Wooster, Cleveland (now the Cleveland College of Physicians and Surgeons), in the winter of 1896, Dr. J. F. Hobson, Lakewood, Ohio, submitting it. Two weeks previously a dog, acting suspiciously, had bitten a boy in Lakewood; the dog was killed and buried, and the lad came to Dr. Hobson for treatment of the wound. His parents became anxious and alarmed, and had the dog's carcass exhumed, and it was brought to the laboratory frozen and in good state of preservation. Three rabbits and one dog were inoculated with an emulsion of the suspected animal's medulla, by the subdural method of Pasteur-Roux; none of these animals developed experimental rabies. But in the interval the boy's parents became more apprehensive and insisted on subjecting him to the preventive treatment. Accordingly, on my recommendation, Dr. Hobson sent the boy to the Chicago Pasteur Institute, where he was treated, and finally returned home with no further mishap.

Case 2.—This concerns the late Dr. F. A. Todd, who was first assistant physician at the Toledo State Hospital. While making his rounds Aug. 29, 1898, Dr. Todd was attacked by a large, strange dog, which bit and severely lacerated one of his thumbs. The wounded member was encouraged to bleed freely, afterwards treated with solutions of carbolic acid and formalin, and then dressed. The dog was soon after captured and killed, and Dr. H. A. Tobey, superintendent of the Toledo State Hospital, telephoned to the Pathologic Laboratory of the Ohio Hospital for Epileptics, Gallipolis, notifying me of the accident and seeking advice. At my suggestion the dog's carcass was at once shipped, reaching the laboratory, packed in ice, the afternoon of August 30. With an emulsion of the dog's medulla two rabbits were at once inoculated by the subdural method. Dr. Todd was advised by me, both in the first conversation by telephone and in several subsequent letters, to resort to the preventive treatment, and I again recommended the Chicago Pasteur Institute. Dr. Todd, however, seemed reluctant and even indifferent until September 12, when he telephoned me that the suspected dog had, previously to attacking him, bitten two other dogs, one of which was at large, and the other confined by a veterinarian, who had just informed him that it had developed paralytic rabies and had been killed. That evening Dr. Todd went to Chicago and began the Pasteur treatment on the following day. On September 17 both the inoculated rabbits showed symptoms of experimental rabies of the paralytic type, and the smaller one died September 18, the larger one September 19, of this disease. From the first of these two animals a second series of rabbits was inoculated, and these died of paralytic rabies after the usual incubation period. Dr. Todd had followed all the events up to the moment of subjecting himself to treatment with calm, intelligent interest, and, in response to his special request, and after consultation with Dr. Tobey, I informed him of the results of my experiments with the first series of rabbits—September 18. Even before this time he had suffered with pain and beginning inflammation in the bitten thumb, with pains in the back and abdomen, and had been melancholy and depressed. On September 27 the doctor developed pronounced symptoms of hydrophobia, and three days later he died of this disease after a most agonizing ordeal. Although every effort was made by Dr. Tobey and myself, no portion of the spinal cord removed in the autopsy on Dr. Todd, could be obtained, thus leaving the question of laboratory hydrophobia or street rabies open. There can be no doubt, however, as to the genuineness of this sad case, for the experimental inoculations in the rabbits were perfectly typical in their results; lately I have obtained additional confirmation by submitting a spinal ganglion of one of the rabbits, which had fortunately been preserved along with the spinal cord, to the Van Gehuchten-Nelis histologic test, here finding the characteristic ganglionic changes.

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Stengel, W. S. Hall and L. Hektoen.

Case 3.—This case came to my laboratory at Gallipolis from Defiance, Ohio, Nov. 14, 1898. The dog, whose carcass was sent for examination, had bitten several school children, and the city authorities took the matter in hand, sending the children to the Chicago Pasteur Institute, and the dog to me for examination. I made subdural inoculations in three rabbits with absolutely negative results. In due time the children were returned home and no trouble was experienced.

Case 4.—A suspected dog, which had bitten several other dogs in Gallipolis last January, was brought to the laboratory within a few hours after being killed. Experimental inoculation of two rabbits proved negative, and none of the dogs developed rabies.

Case 5.—This was submitted by Dr. J. W. Long, Bryan, Ohio, March 5, 1901. Here a dog had bitten two men and one boy, after which it was killed and the head and neck expressed to the Pathologic Laboratory of the Ohio Hospital for Epileptics, reaching here March 6, in good condition. Three rabbits were at once inoculated with an emulsion of the dog's medulla by the intracerebral method of Leclainche-Morel, and another by the intranasal method of Galli-Valerio and Solomon. The cervical spinal ganglia of the dog were at once subjected to histologic examination, and the lesions of the Van Gehuchten-Nelis reaction were recognized, so that, thirty hours after the dog's head arrived I telegraphed Dr. Long of the positive indications of the histologic test and urged him to submit his patients to the Pasteur treatment, this time in the Pasteur Department of the Baltimore City Hospital; he did this at once. Between March 20 and 21 the three rabbits of the Leclainche-Morel inoculation died of typical paralytic rabies, and on March 22 the one subjected to nasal inoculation died in the same manner. A second series of inoculations in rabbits has since been positive. The ganglia of the first series of rabbits, including the cranial, spinal and sympathetic, have been carefully studied by the Van Gehuchten-Nelis method, all with typical results. This I shall endeavor to show you by the microscopic demonstration which you will find in the pathologic exhibit. The patients returned home after the full course of preventive treatment at Baltimore and up to the present moment are entirely well.

SUMMARY.

1. Four instances in which human beings were bitten by dogs suspected of rabies were tested by laboratory methods with positive results in two. All the patients were given the preventive treatment.

2. In three cases the patients were treated at the Chicago Pasteur Institute, and here the only one positive by laboratory test died of rabies in the midst of treatment, presumably because the inauguration of treatment was somewhat delayed and because the stage of incubation was remarkably short.

3. In the fourth case, conclusively demonstrated as rabies in the laboratory, the patients were promptly treated in the Pasteur Department of the Baltimore City Hospital, and they have given no evidence of the disease six months after having been bitten.

DISCUSSION.

Dr. Frank J. Hall, Kansas City, Mo.—I had a case of hydrophobia when I was not familiar with this method of differentiation and made a search at that time for the so-called "tubercles of Babes," but failed to find them. I did, however, find a great quantity of strongly pigmented leucocytes surrounding the vessels in the chord, in the brain and in the parotid gland. I wish to ask if these leucocytes have been observed by the reader, and if he considers them of any diagnostic importance, or are they observed frequently in this disorder? I had a large white bull-dog that had "gone mad" and, keeping it under observation until its death, prepared an emulsion from the medulla, and inoculated this material into the anterior chamber of the eyes of rabbits. The animals never showed the symptoms of hydrophobia and, therefore, we failed with that method. The eyes of the inoculated animals became very much swollen and became translucent as if injected with water, but aside from that, there were no changes at all. The certainty that my dog was a victim of hydrophobia was proven by the fact that a horse bitten at the same time that the three human beings were bitten, died of hydrophobia 42 days later.

Dr. A. P. Ohlmacher, in reply—Concerning the presence of pigmented cells, I will say that while I have had some experience in studying the histology of the hydrophobic condition, and have made an examination of the spinal cord from a number of experimental cases, I believe I have not seen these pigmented cells, or, if they have been seen, I have not thought that they had any special relation to the morbid process attending hydrophobia.

THE NEWER PATHOLOGY OF THE RETINA.

WITH SPECIAL REFERENCE TO THE CHANGES PRODUCED IN THE GANGLION CELLS BY CERTAIN TOXIC AGENTS.*

HARRY FRIEDENWALD, A.B., M.D.

Associate Professor of Ophthalmology and Otology, College of Physicians and Surgeons.

BALTIMORE, MD.

In looking through the text-books of ophthalmology of fifty years ago we are struck by the extensive group of amblyopias and amauroses. Ruete describes thirty-seven varieties. The terms were convenient, for as we read in Faust

> Denn eben wo Begriffe fehlen
> Da stellt ein Wort zur rechten Zeit sich ein.

By the aid of ophthalmoscopy and of pathology this great category has been reduced more and more, until now there are but a few important classes of cases for which these terms are still considered useful. Prominent among them are the toxic amblyopias. These have gradually assumed greater and greater importance. The clinical symptoms produced by the various poisons and the character and degree of the visual impairment are now quite well known. Our knowledge, however, of the pathological changes upon which these depend, of the location of the lesion in the visual apparatus, is far from being established. It is our purpose to review briefly the recent studies of this subject and note the conclusions we may draw from them.

I must begin by directing your attention to the great advance made in the histology of the nerve cell through the recently discovered methods of selective staining of different portions of the cell substance, methods which are particularly associated with the name of Nissl. For, while the older methods of staining enabled us to recognize the general structure of the nerve cell with its nucleus and nucleolus and the Golgi-Cajal and Ehrlich methods exposed their numerous ramifications and connections, the intimate structure and composition of the cell is only now revealed to us by the Nissl method. This observer has shown that the cell body contains substances which react very differently to his stains. While portions of the substance remain colorless, other parts take on an intense stain. These are known as the chromatic substance and often called the Nissl bodies.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs J. A. Lippincott, Casey A. Wood and H. V. Wiirdemann.

While varying greatly in different forms of cells they are sufficiently constant under the same normal conditions to lead Nissl to regard them as indices of the normal or abnormal structure of the nerve cell.

The researches made by means of this method in the ganglion cells of the retina are not as yet extensive. Those that have appeared are important not only for their reference to the organs of vision but also in their bearing on general nerve histology.

Mann,[1] Bach,[2] Abelsdorff[3] and others have studied the retina under normal conditions, and Dr. Ward A. Holden[4] used the method to determine the effects of quinin and methyl alcohol. The most extensive and important work upon the subject appeared recently from the pen of Birch-Hirschfeld.[5] This observer first endeavored to determine the normal condition of the retina, the variations of the nerve cells in different species of animals, the effects of various hardening fluids and of different staining methods, and of postmortem changes. Next, he investigated the effect on the retina of protection from light or of exposure to various intensities of daylight and of the electric arc light.

It is not possible for me to enter into the details of these results, but it is necessary to state that they were definite and constant under the same conditions. His illustrations showing the normal appearance of the retina (the stain was thionin and erythrosin), as well as those of Abelsdorff are here shown.† You will see that the retinal ganglion cells contain the intensely blue Nissl bodies, between which there is the unstained substance. In the eyes which have been subjected to light the Nissl bodies are somewhat more diffuse than in those in which the eye has been kept in the dark. One drawing shows the effect of exposure for five minutes to a brilliant electric light; the Nissl bodies of many of the cells are almost entirely lost. In another eye treated in the same manner but allowed to recover for one hour in the dark the Nissl bodies are regenerated and show normal conditions.

QUININ.

Various theories had been expressed concerning the action of this drug on the retina. Obliteration of the caliber of the vessels through endovasculitis on the one hand, through irritative contraction on the other were assigned as causes. De Bono[6] in 1894 thought that its action was that of a plasma poison on the terminal retinal cells. It was Dr. Holden, as I stated before, who was the first to investigate its effect on the retinal ganglion cells by means of Nissl's method. His results showed that there were no histological changes in the vessels of the retina or nerves. He found a "constriction of the retinal vessels and particularly of the arteries followed by a highly albuminous serous exudation into the nerve fiber layer and a degeneration of the ganglion cells together with their axis cylinder processes which become the centripetal fibers of the optic nerve." The degenerative changes in the ganglion cells manifested themselves by the formation of vacuoles, wandering of the nucleus toward the periphery of the cells and disintegration and disappearance of the chromatic substance.

He states that "there is no way of determining exactly how far the degeneration of the ganglion cells and their axis-cylinders may be due to the direct toxic action upon them of the cinchonized blood, and how far the degeneration may be due to the indirect toxic action of quinin in constricting the retinal vessels, and thus reducing their nutritive supply." He inclines to the view that "the changes in the retina in quinin amblyopia are due chiefly to deficiency of nutritive supply, and, to a lesser degree, to alteration in the quality of the nutritive supply."

Birch-Hirschfeld* has repeated Holden's experiments on rabbits and on dogs. The results were uniform. The ganglionic cells showed slight decrease in size, blurring or obliteration of the outline of the cell and the formation of smaller or larger vacuoles. The most important change was in the chromatic substance. In most cases this was still to be seen as fine particles lying peripherally. The nucleus was sometimes swollen, sometimes shrunken, the nucleolus showed irregularity in form and was situated peripherally in the nucleus. The cells of the inner nuclear layer likewise showed signs of degeneration. Vascular lesions were absent.

In order to determine whether these changes were due to the direct toxic influence on the nerve cell or were the indirect results of contraction of the vessels, he determined the effect of experimental anemia on the retina by tying the common carotid. The results were marked, but sufficiently different to lead him to conclude that the ischemia produced by contraction of the retinal vessels does not suffice to explain all the changes found in quinin intoxication. He assumes that the additional factor is the direct action of the poison on the nerve cell. There was nothing to indicate that the retinal changes are secondary to nerve changes; on the contrary, the former were found before any changes could be seen in the nerve.

Drualt[7] also reported experiments on dogs. He obtained typical changes. "At the end of ten hours one can already recognize very advanced chromatolysis of the ganglion cells and in some even complete destruction of the chromatic substance."

He also describes the changes produced in the ganglion cells by cutting the optic nerve behind the entrance of the central retinal vessels. In this experiment he claims that the retinal ganglion cells disappear at the end of ten to twenty days.‡ He maintains that if the optic nerve is cut and quinin is injected subsequently at a varying interval that the degenerative changes will be similar in both eyes when the interval is short (two days), but that when the interval is long (six days) the degeneration will be very slight after the injection of quinin.[13] He concludes that as the cells lose their normal condition as a result of neurectomy they also lose their susceptibility to the poisonous effect of quinin. Inasmuch as vasomotor influences are unaffected he believes the poison must act directly upon the cell. It is probable that the early changes in the nerve cell, so long as they affect only the chromatic substance, are possible of repair; when the degeneration has attacked the body and the nucleus of the cell its function is probably permanently destroyed. Birch-Hirschfeld cites the view of Goldsheider and Flatau[14] that the Nissl bodies have no vital importance but are significant in that they reveal the earliest pathological changes in the cell.

† The illustrations were passed around.

* He criticises Holden's results on the ground that postmortem changes were not sufficiently excluded and that the method of killing the animal (by chloroform narcosis and bleeding to death) may in itself have been productive of certain changes. He killed his animals by a blow on the neck and the eyes were immediately removed.

‡ This is not in accord with Birch-Hirschfeld, who describes marked signs of chromatolysis 55 hours after the section; in five, ten and fifteen days these changes are more distinct, but he does not suggest the entire disappearance of cells.

Thus we see that Holden's experiments are on the whole confirmed. And we may now take it as an established fact that quinin causes blindness by its action on the retina and not on the nerve.

Parinaud[15] believes that the toxic action is on the entire neuron from center to periphery. This view is purely suppositional and without any experimental basis.

FELIX MAS.

DeSchweinitz[8] was unable to produce any change either in the nerve or in the retina in his experiments on dogs. Masius and Mahain in 1899† found marked atrophy of the nerve fiber layer, dilatation of the capillary vessels, thickening of the septa, atrophy of the optic nerve, with the formation of vacuoles in the nerve. The retinal changes were slight excepting some chromatolysis of the ganglion cells in the central fossa. They concluded that the lesions were primarily in the nerves, depended on vascular changes and that the retina suffered secondarily. Birch-Hirschfeld succeeded in experiments with this poison on rabbits. He was unable to find any ophthalmoscopic changes, but his cases showed varying degrees of change in the inner nuclear layer and in the ganglion cells, i. e., aggregation of the chromatic substance in lumps, or its disappearance, shrinkage of the nucleus and disintegration of the cell; the inner nuclear layer presented a hyperchromatic and shrunken condition of the nuclei. He maintains the degeneration and atrophy of the nerve fibers is secondary to the retinal changes.

Okamoto[9] recently reported slight swelling of the medullary sheaths, atrophy of the axis-cylinders and hyperplasia of the interstitial tissue.

Nuel[10] has likewise recently published the results of his experiments with felix mas. They are summarized in the following sentence: "Filicic optic neuritis is a parenchymatous neuritis characterized by a primary lesion and destruction of nerve fibers; only later are secondary changes produced in the interstitial tissue, first in the neuroglia and afterwards in the vessels and connective tissue. In certain parts of the nerves the subsequent changes assume exactly the characters that are considered pathognomonic of the neuritis called interstitial."

These views are in direct contradiction to those generally accepted by ophthalmopathologists and must await satisfactory confirmation. At present it appears probable that the changes produced by felix mas are to be found in the inner nuclear layer and the layer of ganglion cells as shown by Birch-Hirschfeld, and that the changes in the optic nerve are secondary.

BISULPHID OF CARBON.

This produces amblyopia of the alcohol-tobacco type; it was used by Birch-Hirschfeld in experiments on rabbits. The same poison has been found by Köster[16] to produce characteristic changes in the spinal ganglion cells. Birch-Hirschfeld's results were practically negative so far as the retina was concerned. This justifies the opinion that the primary changes are not produced in the retina but elsewhere, in all probability in the optic nerve.

ALCOHOL.

Holden in one case produced degenerative changes in the ganglion cells of the retina and some medullary sheaths of the optic nerve by means of methyl alcohol and he concluded that this form of amblyopia is due to "nutritive disturbances in the ganglion cells of the retina."

This view has recently been opposed by Gifford, chiefly on the ground of McCoy and Michael's case of optic neuritis from methyl alcohol. Birch-Hirschfeld criticises these objections because the case referred to stands alone among all in which no neuritis could be detected.

Birch-Hirschfeld's experiments were made on rabbits and chickens, and his results were definite. The early changes consist in the chromatic bodies of the ganglion cells losing their sharp definition and the substance of the cell taking up the stain, while the body of the cell becomes shrunken. Then the nucleus shrinks, becomes irregular and shows signs of degeneration. Finally the outline of the cell becomes indistinct and a shrunken nucleus alone marks the former location of the cell. The inner and outer nuclear layers likewise show degeneration, especially the inner. The retinal vessels were normal. The optic nerves showed no lesion excepting in one case—the one in which the retinal changes were most marked. In this there was a section of degeneration in the nerve but even here there were normal fibers among the degenerated ones. There were no interstitial changes in the degenerated portion of the nerve. Hirschfeld, therefore, concludes that experimental methyl alcohol amaurosis depends primarily upon lesion of the retina—first of the ganglion layer, later of the inner and outer changes in the optic nerve. He emphasizes the remarkable analogy between the optic nerve changes just described and the picture which the degenerated optic nerve of ethyl alcohol amblyopia presents. Neuritic changes were absent in the rabbit's nerve; he suggests that perhaps the period of intoxication in the rabbit (14 days) had been too short, and also cites Heilbronner's[17] observations as showing that the connective tissue changes in peripheral alcohol neuritis are secondary.

It is not possible to draw reliable conclusion as to the effects of ethyl alcohol on man from these results of methyl alcohol. Uhthoff[18] properly warns against accepting the results on animals as necessarily identical with those on human beings and especially the effects of the long-continued chronic poisoning as usually observed in man.

AUTHOR'S EXPERIMENTS.

In order to determine the effects of chronic alcohol poisoning the writer fed rabbits with absolute ethyl alcohol, pure methyl alcohol, commercial methyl alcohol and Jamaica ginger (made of 95 per cent. methyl alcohol).

I desire here to give in brief the results on four rabbits to which they were given in small amounts (5 to 10 c.c.) for a period of almost four months. The rabbits lost weight, but otherwise remained apparently healthy, and were killed by a blow on the back of the neck. The eyes were immediately removed and one of each animal hardened in 96 per cent. alcohol, the other in saturated bichlorid of mercury solution. The sections were cut and stained under the direction of the well-known neuro-pathologist, Dr. Stewart Paton, the director of the laboratory of the Sheppard-Pratt Hospital for the Insane. The effects of all four substances were similar. As yet it is impossible to state any specific differences.

The ganglion cells show marked signs of degeneration, but the inner nuclear and outer nuclear layers are likewise affected, especially the inner. Many ganglion cells show great shrinkage and atrophy; the chromatic sub-

† Cited by Birch-Hirschfeld.

stance is broken down and granular. Other cells show no nuclei or nuclei very irregular in shape. In other cells again the chromatic substance appears fused so that it forms an almost complete ring around the nucleus, in which case the cells are more or less irregularly contracted and the parts where the processes leave the cells are also shrunken. This change is suggestive of chronic cell degeneration. Some ganglion cells in which the cell body has disappeared, leaving a faint nucleus, suggest the acute degeneration described by Nissl.

It is very significant that the ethyl and methyl alcohols produce similar changes in chronic poisoning. I shall not venture to say whether these changes in the retina are primary or secondary to optic nerve lesions, though I incline to the former view. The question can not be answered until more extensive experiments which the writer has in contemplation are concluded. But it must be admitted that in producing these retinal changes by *chronic alcohol poisoning* we have made an important advance in the solution of the same chronic poisoning in man. I shall give a detailed report of these experiments elsewhere.

In concluding this paper I desire to point out the review given by Uhthoff[11] at the last International Ophthalmological Congress in Paris in August, 1900, on "Toxic Neuritis." He divided this into two groups: first those toxic amblyopias that present a central scotoma and normal periphery of the field; these are the partial retrobulbar forms due to alcohol, tobacco, bisulphid of carbon, arsenic, iodoform, stramonium and hashish. The second group shows changes in the blood vessels with secondary ischemic necrosis, and in addition there is direct poisonous action on the nerve cell. He notes that the constriction of the vessel alone can not explain the affection, for ergot with its powerful constrictive action is not known to produce such destructive changes.

Uhthoff is one of the most formidable champions of the neuritic theory, so far as the alcohol tobacco group is concerned. His arguments are based on the pathologic findings in his eleven cases of alcohol and tobacco blindness, in which the optic nerve was subjected to microscopic examination and in all of which, evidences of neuritis beside the atrophy of the nerve fibers were found. He therefore refuses to regard the condition as a simple degeneration.

Siegrist[12] has likewise recently written a strongly argumentative article opposing the view that the optic nerve lesions in alcohol and tobacco amblyopia are due to primary retinal lesion with ascending degeneration. It is difficult to harmonize the results of experimentation on animals and the pathologic findings of partial neuritic atrophy of the optic nerve in man.

At present the only possible way is to assume that, as Heilbronner, and recently, Nuel, have endeavored to prove, the neuritic changes are secondary to a primary degeneration of the nerve fiber. But it is wiser still to await the results of more extensive experimental and pathological research.

ATROPHY OF THE RETINA.*

DUDLEY S. REYNOLDS, A.M., M.D.
LOUISVILLE, KY.

It may be sometimes quite impossible to discover the cause of disease, and it is not always easy to determine whether a lesion is dependent upon some other morbid process, or of primary origin. I have hesitated to believe it possible for atrophy of the retina to come on as a primary condition, without any discoverable preceding inflammation, or even hyperplasia; but, it is certain that. whatever disturbances may have preceded the beginning of atrophic changes in the two cases herein reported, there was no manifest hyperemia before failure of sight. I am not sure that some occult inhibition of the functions of the vasomotor nerve force may not cause primary atrophy.

Miss M. B. J., aged 19, came to me July 12, 1882. with a note explaining that she had been unable to pursue her studies without headache. After suspending her accommodation, I found that, with +1/30 C. ax. 90° for each eye she saw 20/XX, Snellen. She returned home and got along satisfactorily with her studies until April, 1888, when I received a letter telling me she had suddenly experienced difficulty in reading at night, and could not distinguish the color of roses.

She returned to Louisville, when I found this difficulty had increased progressively until she was no longer able to read on cloudy days. Her fields were irregularly contracted, and she had no perception of either red or green. Her general health seemed to be perfectly good. The menstrual function was normal. Her sight was now reduced to 20/LXX, Snellen, in the right eye, and 20/C in the left. She remained with relatives in the city until June, when she was unable to see the test type, even at 10 feet with any glass. She could not differentiate colored lights. Ophthalmoscopic examination showed nothing definite. Her fields were extremely contracted. she had central scotomata in both eyes. She went with her grandmother to New England to spend the summer; and in August consulted Dr. Hasket Derby, of Boston, who found "the central vessels of the retina extremely small, with no abnormal appearances of the discs. She is unable to distinguish any test object."

The first week in September she returned to Louisville and I again mapped her field of perception. Both fields showed increased peripheral contraction, with central scotomata of irregular outline. She described everything as "smoky and blurred." In brilliant illumination, a book held before the face seemed "covered with a fine gray network." November, she was unable to distinguish any objects. On bright days everything

*Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

seemed so dark and indistinct, she felt as if she were in a dense fog. Looking at any bright light, she was annoyed with a gray network before her. Artificial lights seemed smoky, and she said "it seemed covered with a dark mosquito net."

The ophthalmoscope showed at this time, faint grayish striations in the region of the macula, and near the larger vessels around the disc. The larger retinal vessels were scarcely visible beyond the discs, while the latter seemed perfectly normal.

She has remained in this condition until the present time. No other member of this young lady's family has suffered with blindness in any form, although a large number of her close family relations have various kinds of optical defects, for which I have prescribed; yet, none of them have retinal, or choroidal disease. There was no evidence of hereditary blood taint, and no sign of toxemia. I felt obliged to consider this a case of primary atrophy of the retina, advancing in both eyes to the extinction of useful vision, probably due to excessive exposure of the eyes to the bright sunlight, as she was accustomed to read in the sun.

Miss H., aged 17, of Frankfort, Ky., consulted me on Nov. 12, 1892. She had been having headaches, so severe as to interrupt her studies at school. With accommodation suspended, she saw with +1/60 C. 90° = 20/XX in the right eye, and with +1/48 C. 90° = 20/XX in the left. There were no ophthalmoscopic signs of disease. She returned home and resumed her studies. March 6, 1895, amblyopia had appeared to a degree sufficient to make reading impossible. Sight in the right eye = 6/XVIII, and in the left = 6/IX. I was astonished to find that now no glass improved the sight. Her fields of vision were irregularly contracted, with comet-shaped scotoma in the field of the right eye. The left was obscured by a veil-like mist with incomplete central scotoma. She had no color perception in either eye. Ophthalmoscopic appearances at this time were great narrowing of the retinal vessels, the larger ones only being easily traced. Light grayish striations in different portions of the field seemed to occupy the vicinity of the contracted vessels. May 17, 1895, the retinal vessels were empty, and not visible except in the discs, and faded away within two millimeters of the papillæ. She had always enjoyed good health, and there had been at no time any sign of inherited blood taint or toxemia. The discs were at each examination perfectly distinct in outline, and apparently normal. March 5, 1900, she came with her sister, and on careful examination I found it very difficult to trace even the outlines of the larger vessels of the retina, even to the margins of the discs, while numerous pale grayish striations occupied the region of the macula, and, radiary streaks of gray following the direction of the closed vessels around the discs. The discs appeared entirely sound and normal. Both eyes appeared alike. The pupils were moderately dilated, and responded but slightly to concentrated light. She could see shadows of objects passed between the eyes and a strong light. Artificial lights appeared pale gray, and seemed covered with a heavy mist or fog. I could find nothing as to any probable cause of the atrophy in this case.

Drasche and Weinlechner Reach the Age Limit.—Professors R. von Drasche and Weinlechner took leave of their charge in the Vienna public hospital recently, as they had reached the age limit. The occasion was rendered memorable by tributes from their colleagues and pupils.

A CASE OF BLINDNESS FROM DRINKING BAY RUM, COMPARED WITH THE REPORTED CASES DUE TO METHYL ALCOHOL AND TO ESSENCE OF JAMAICA GINGER, ETC.*

H. MOULTON, B.S., M.D.
OCULIST AND AURIST TO BELLE POINT HOSPITAL.
FORT SMITH, ARK.

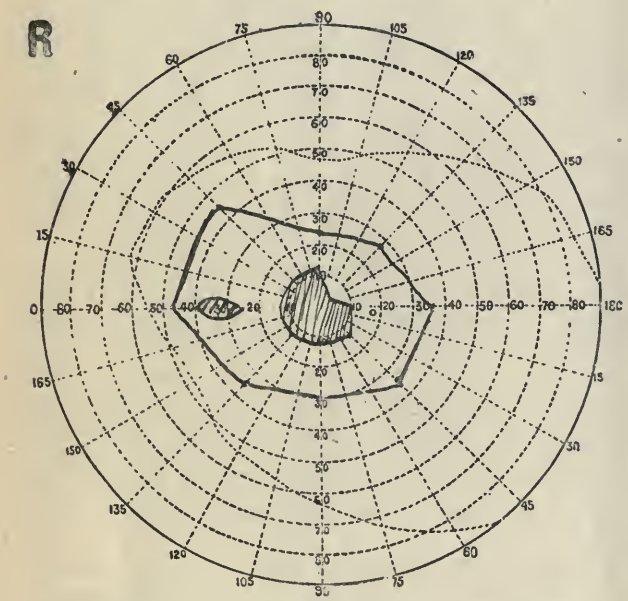
For some time the idea has been entertained that wood alcohol is the toxic agent in cases of amblyopia following the drinking of essence of Jamaica ginger and similar preparations. Dr. Hiram Woods thought of, but seems to have rejected the idea which Dr. Jackson more lately advocates.†

We will remember that reports of these cases began to appear nearly at the same time with reports of the cases due to wood alcohol. While bay rum and various essences have been long used as substitutes for whisky in prohibitory districts without accident, there have recently occurred several fatalities. I personally know this fact to apply in the Indian Territory, where the United States prohibition is very rigid. Within a year or two there have been several deaths in that country from drinking these things as well as wood alcohol. Ordinary wood alcohol has a characteristic odor and taste so disagreeable as to have formerly prohibited its use in pharmacy, but the more recent method of preparing it, under the name of "Columbian spirits," removes to a large degree its objectionable features, so that such use is possible. Its cheapness, too, recommends it as a substitute in part at least for ordinary alcohol, in such preparations as are sold at cheap price in country stores.

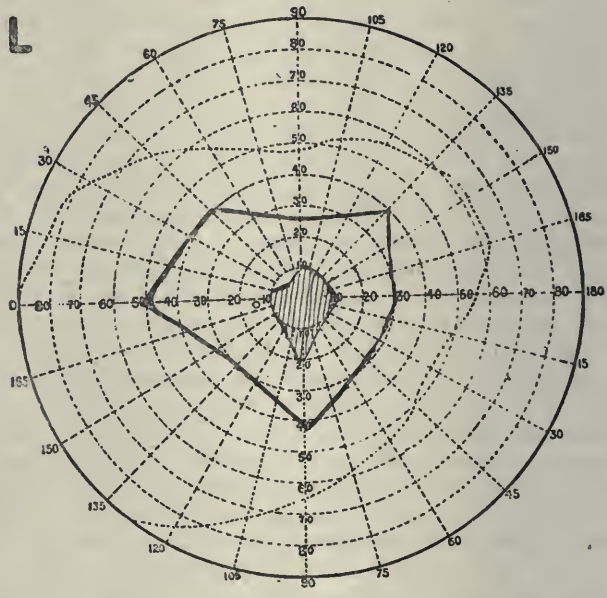
Moreover, it seems in some quarters to be considered non-toxic in this purified form. (Prof. J. H. Long, personal communication.) This is, however, refuted and shown to be dangerous by the reports of Gifford and of Patillo. Professor Long (same communication) states that it is rapidly coming into use in pharmacy, especially in making bay rum and kindred preparations. Dr. Harlan had a chemist demonstrate by analysis the presence of wood alcohol in the essences of ginger and peppermint drank by the patients whose cases he reports.

It is worthy of note that we know of no other substance which when swallowed selects for attack with such uniformity the optic nerve and retina. Those who record cases of blindnes due to this cause mention in all thirty persons who drank from one to two drams to an ounce or more of the substance, and were made sick by it. Fifteen, or 50 per cent., lost their sight. One of the first cases on record was published by the present writer in 1899. Four preceded and others have followed, till now fifteen or more are described in literature. A dozen or more cases from essences also are reported, a sufficient number to afford reliable data for comparison. An analysis of fifteen cases of wood alcohol blindness, and of twelve cases of blindness due to the essence of Jamaica ginger, etc., proper references to which are given in the appended bibliography, shows the striking identity of important symptoms.

In each group, unless the dose was large enough to produce coma, no unusual symptoms presented on the first day. Usually on the second or third day, sometimes later,



* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.



† Dr. Woods afterwards accepted this idea.

the almost constant history is of nausea, vomiting, headache and dizziness. Visual disturbances are delayed for a day or two longer. In about twelve to forty-eight hours blindness becomes total. In a few days some even useful vision is restored, only to be lost again in a short time. In every case where the field of vision was studied, a central scotoma was demonstrated, except once, namely, in Stieren's case of ginger poisoning. Narrowing of the field was equally characteristic. Atrophy of the papilla was universal, most pronounced in the temporal half and preceded in a few cases by a low grade of visible neuritis. In about half of each group the retinal vessels were narrowed, in the other half normal. Other symptoms are "excitement," "coma," "semi-coma," "depression," "coming and going of sight," "sensitiveness to pressure and to movement of eyeballs," etc. Only two cases recovered normal vision, one in each group.

The two cases following illustrate beautifully the clinical identity of the two classes of cases. The first is from my own practice.

William Leslie of Talequah, I. T., aged 25 years, colored, was seen Oct. 23, 1900. His health and eyesight had been good until Sunday, Sept. 18, 1899, when he and

two companions drank a pint bottle of bay rum. Two of the men kept quiet and were in no way affected, but our patient, who drank more than the others, kept up vigorous exercises by riding a bucking pony all day. He went to bed that night and slept soundly. Next morning at sunrise he noticed an uneasy sore feeling about the eyes, and shortly afterwards a failure of sight. At 8 o'clock he vomited, and again frequently during the day. By night he was totally blind. During the two following days he felt "deathly sick," but by Thursday felt as well as usual, excepting that he was blind. He said that during the time that his eyesight was going from him, his central vision failed first while he was able still to perceive objects at a little distance from the blind area on either side. Three weeks later some vision surrounding a central dark spot returned, but was soon lost. He has remained without light perception ever since. There is slight lateral nystagmus. The pupils are dilated and rigid; tension is normal and media are clear. The retinal vessels remain of normal size. The optic discs are opaque, white and level with the surrounding retina. The edges are not furred, but the lamina cribrosa is invisible. There is, however, a slight but well-marked physiological cup. The nasal halves only of the discs retain a slight pinkish hue.

The other case occurred in the practice of Dr. E. C. Ellett of Memphis, to whom I am indebted for the notes and accompanying charts. O. L., male, white, aged 28, was seen Nov. 28, 1899. On April 6, 1899, while on a spree, he drank one-half pint of wood alcohol by mistake. Within three hours was comatose, and remained so on and off for four days (still intoxicated). When he recovered vision was reduced to perception of light. This improved, and about April 29 he could see to read a paper. It again became worse, and has remained so. Vision now counts fingers excentrically at five feet. The grounds show optic atrophy with cup 2 D. deep. The vessels are slightly narrowed. Central scotoma is as shown on charts.

The important point is that various substances liable to be drank may contain wood alcohol, and that we should be able to make a diagnosis from the symptoms, the most important of which are, at first, gastro-enteric disturbances when the dose is small, and coma when it is large, folowed by rapid failure of sight, which later improves, but soon relapses; contraction of the fields and absolute, usually, central scotomata, and sometimes total blindness. These are symptoms of retrobulbar neuritis, but the cases of retrobulbar neuritis of the text-books mostly recover; these do not. More than 90 per cent. permanently lose useful vision.

SYNOPSIS OF WOOD ALCOHOL CASES.

Mengin (Viger): 1879. Headache, vomiting, delirium, etc. Blind on second day. Improved, but finally totally blind. White atrophy. Vessels normal.

Kuhnt: 1899. Took one swallow. Headache, nausea, semi-coma. Blind on 5th day. Eyeball painful to movement and pressure. Pilocarpin. Recovery in one month. At first, discs pale; arteries narrow, normal later. A second case died of gastro-enteritis after having become blind.

McCoy and Michael: 1898. 120 c.c. Early total blindness. Improvement, then relapse. Two fingers, one eye; projected light, in other. Neuritis passing into atrophy.

Moulton: 1899. Half pint. Weakness, semi-coma. Blind in 24 hours. Improvement, relapse. V-fingers at 1 foot in L. E.; R. E. equaling L. P. Contracted field. Central scotoma. White atrophy. Narrow vessels. (Five men drank

about same amount; two died; one went blind; two recovered without eye symptoms.)

Callan: 1899. Notes not available.

Gifford: 1899. Two to three oz. Headache, vomiting. Totally blind 4th day. Improvement; central scotoma. Later totally blind. Atrophy. Narrow vessels.

Gifford: Another case was blind in 24 hours, and died in 48 hours.

Gifford: A case observed by Foster is described who drank a small amount. Blind in 24 hours. Wildly excited and soon died.

Patillo (also Casey A. Wood): 1899. Inhaled fumes four days. Nausea, etc. Blind on 6th day. Improvement and relapse. R. E. equaled fingers at 3 feet; L. E. equaled L. P. Central scotoma. Atrophy. Vessels: right, normal; left, contracted.

Patillo: Inhalation for two weeks. Headache, nausea, etc., for two days. Blind on third day. V. equaling fingers 1 and 3 feet for L. and R. E. respectively. Central scotoma. Atrophy. Vessels normal.

Raub: 1899. Two to five drams. Blind in 6 days. Improved, relapsed to total blindness. Atrophy.

Raub: 1899. Semi-conscious 4 days; then blind. Improvement. Final blindness. Atrophy.

Jackson: 1901. Coma 48 hours. Blindness on waking. Improvement. Relapse. Atrophy.

SYNOPSIS OF GINGER, ETC., CASES.

Thompson: 1897. One and a half quarts. Headache, nausea, etc. Blind on 5th day. Improvement; relapse. Fingers for R. E. at 3 feet; L. E. equaling 1/100. Central scotoma. Atrophy, especially papillo-macular.

Woods: 1899. Drank for 5 or 6 days; then blind. Improvement; relapse. Can see only large moving objects. Central scotoma, atrophy; vessels normal.

Woods: 1899. One or two pints. Nausea, etc. Blind in twenty-four hours. V. improved, then stationary. Fingers at 6 inches. Atrophy; furred papilla. Narrow arteries.

Woods: 1899. One pint. Coma, nausea. Blind in 48 hours. Improved to get about. Fingers R. E. at 10 feet; L. E. at 20 inches. Scotomata in contracted fields. Papillo-macular atrophy.

Woods: 1899. Six ounces. Headache. Gastro-enteric symptoms. Blind on 3d day. Papilla. At first normal; later atrophic.

Woods: 1899. Seven bottles. Vomiting, headache, etc. Blind on 3d day. Neuritic atrophy.

Woods: 1899. Twenty ounces. Ginger and peppermint. Nausea, etc. Blind in 48 hours. Eyeballs sensitive to touch or movement. Improvement. Finally blind. Neuritis followed by atrophy.

Stieren: 1901. Twelve ounces. Blind in 12 hours. Recovery after prompt and vigorous treatment, principally with pilocarpin.

Harlan: 1901. Fourteen bottles. Coma. Blindness 4th day, nearly total. V. varied some weeks, then total blindness.

Harlan: 1901. Three and a half bottles peppermint and lemon. L. P. 4th day. Under pilocarpin and strychnin improved to 6/200. Atrophy. Fields small and irregular.

Dunn: 1901. Dunn's two cases, though seen late, had rather more than the average vision; but the nerves were atrophic with vessel changes.

NOTE: Since writing this paper, De Schweinitz has recorded (*Oph. Rec.*, June, 1901) a case due to inhaling wood spirits from varnish. This case also improved, but finally became totally blind with nerve atrophy and contracted vessels.

Gifford has also added another case. (*Oph. Rec.*, July, 1901.) Two or three drinks caused blindness on the fourth day. Treatment was begun immediately with iodid and pilocarpin, with recovery of final vision equaling nearly 20/20, with atrophic nerves and contracted fields. There were ophthalmoscopic signs of neuritis. It is worth noting that in this, the treatment was begun as in Kuhnt's and Stieren's cases within a few hours of the onset of blindness, and to this fact it is reasonable to attribute success. In most of the other cases rational treatment was begun late.

Dr. A. B. Hale, of Chicago, has kindly sent me notes of two cases due to inhalation from varnish. One of them was one of the cases reported by Patillo and Wood. The other undoubtedly is as yet an unrecorded case: "W. H., aged 40, worked seven weeks in open vats, then six days (July 8-14, 1899) in closed vats, and April 26, 1900, was in same condition as Grinette." (Patillo's 1st case.)

DISCUSSION ON PAPERS OF DRS. FRIEDENWALD, REYNOLDS AND MOULTON.

DR. J. M. RAY, Louisville—I can not discuss Dr. Friedenwald's paper from a pathological standpoint, but from a clinical point of view I would like to make a few suggestions. The experimental investigations of Holden seem to point to the retina as the seat of the change resulting from the toxic influence of wood alcohol, but the changes observed with the ophthalmoscope, and the future history of the case, seem to point to the optic nerve as the injured part. The first case of methyl alcohol poisoning that I saw, was in 1896, and Dr. de Schweinitz informs me that it is the oldest case that he has heard of in this country. The case was reported before a local medical society, and the notes were laid aside for future reference and neglected. In that case, a woman, after being out with convivial friends returned home and shortly after retiring became thirsty. In looking around for something to satisfy her thirst she encountered a bottle marked "alcohol." Diluting this with water she drank it. The following day she suffered much from nausea and vomiting. This persisted, and the next day she noticed a blurring and dancing of objects. On the third day she was blind and I was called to see her. At the first visit, I found the patient blind, with semi-dilated pupils, and a fixed stare. With the ophthalmoscope, a hyperemic disc and a fuzzy retina surrounding, was all that could be discovered. The disc eventually became edematous, with the blood vessels full and the retina hazy, this haze gradually fading toward the periphery. The blindness remained absolute for three weeks; then peripheral vision began to appear, the edema disappeared, and vision became about 20/20. Then atrophy of the nerve head began to develop, and when I last saw the patient this was complete and only a little eccentric vision remained.

Two years ago I saw a second case: A colored woman drank of a decoction made by an "herb doctor;" this was followed by intense gastric disturbance and blindness. The ophthalmoscopic picture was identical with that noticed in case one, the change seeming to be the greatest in the nerve head, the retina being apparently secondarily implicated and the circulation not much changed. This case followed exactly the same clinical course, vision returning, improving for several weeks, and then gradual failure again, coincidental with the atrophic changes in the nerve head.

DR. HIRAM WOODS, Baltimore—There can be no question in regard to the identity of symptoms in the Jamaica ginger, bay rum and methyl alcohol cases, and that the toxic agent is the same in all. I am not familiar with any form of blindness which gives the clinical features that all these cases show; the intense gastro-intestinal symptoms, absolute blindness after

a few hours or days, gradual return of sight to some useful vision, quick and great variations in visual acuity, and then settling down either into a progressive and permanent atrophy of the nerve, or preservation of some peripheral vision with typical central scotoma. In one of my cases, the man who came under observation early, was in my office one morning unable to see light, but walked three squares to Dr. Harlan's office and saw well enough to select a chair and sit down in it. Before he left this office his vision had fallen again to light perception.

When I reported my Jamaica ginger cases there was but one on record, namely, Thompson's, published in the *Ophthalmic Record* in 1897. De Schweinitz, in his article in Norris & Oliver's "System," the cases of Thompson and myself, with one he observed, as the only ones then reported. My suspicions were excited as to methyl alcohol through a report given me concerning three cases of wood alcohol intoxication on the relief ship *Solace* during the war with Spain. Of those cases two died and one remained completely blind. I went to the Baltimore firm that made the extract of ginger used by my patients, and secured their formula. It called for 95 per cent. ethyl alcohol. I hope Dr. Harlan will have something to say about the analysis of the ginger obtained from this same firm. I think Dr. Moulton has explained the reason for using it in these preparations, namely, that the refinement of it has made it more economical for such use. Three of my cases came under observation within a few days after the blindness begun. In two there were marked, but not high grades of papillitis; just enough haziness around the edge of the papilla to show but not attract attention unless sought for. All these cases went on to total atrophy.

With regard to the position of the scotoma, of two cases, which I did not see, but notes of which were furnished me, one had a central scotoma finally, while the other had lost all vision except for 20 degrees up, down and out from central fixation. The entire visual field in each eye was lost. The lesion, I think, is usually regarded as an acute retrobulbar neuritis of toxic origin. Yet the occurrence of such a lesion from such a cause is not generally admitted. On the report of my cases (*Ophth. Record,* February, 1899) this was demonstrated by quotations from several authors.

DR. A. B. HALE, Chicago—In Chicago there are a number of men using a new shellac for coating the insides of large hogsheads. I have seen two cases in men who had been lowered into these barrels to apply the shellac; they inhaled the vapor from the alcohol and without any use of the poison in other ways have been seriously affected by it. I have learned recently that this shellac is made with methyl alcohol. These cases present a complete picture of optic nerve atrophy with no essential changes in the retina that could be made out, and it seems to me that we must assume that the nerve itself is as much affected as the retina until the pathologists can disprove it, and can show us why the retina does not show gross changes at first.

DR. CASEY A. WOOD, Chicago—I merely wish to draw the attention of the section to the fact that in these methyl alcohol cases we have another instance of the truth observed a long time ago that most cases of toxic amblyopia are instances of idiosyncrasy. We know that not everybody who indulges in tobacco has tobacco amblyopia, and it is the same with methyl alcohol. Several cases that were reported by Dr. Gifford some time ago should be included in Dr. Moulton's list, although at the time it was not clear that they were due to methyl alcohol poisoning. Six men who had been drinking the same beverages developed toxic symptoms of various grades of severity, but only one of them showed any trouble with his vision. One died before the eye symptoms could have developed, while the other four showed no ocular disturbances.

DR. H. HARLAN, Baltimore—I have had no personal experience with the inhalation of methyl alcohol, but I expect the cases published are all right, because the men, in Baltimore at least, who work in the breweries drink as much beer as they crave and never have temptation to drink wood alcohol. In all these cases we must make allowance for the history, however, as it is difficult to get an accurate history from a man who has been on a debauch. However, the symptoms are so perfectly clear that they can hardly be mistaken. I can not help calling attention to a difference in Dr. Moulton's case where the man drinking it in the morning rode a pony all afternoon and had no trouble until the next day. That is an unusual condition.

In regard to my connection with the demonstration of the fact that it was wood alcohol in all the six or eight cases that Dr. Woods reported, I should say that the analysis, which was made by a careful chemist, has never been questioned, although it has been published in the drug journals and spread all over the country. I have no doubt that for the one case of blindness that has occurred there have been ten cases of death from the drinking of these preparations. When one case that I know of occurred in Chrisfield, Maryland, a prominent citizen remarked that it was very remarkable that blindness should occur, but that they thought nothing of death following its use, because it was nothing unusual for an oysterman to be found dead on the street after drinking these preparations. The pharmacists sell those preparations by the gross in some country districts. One storekeeper in Virginia, made blind by drinking essence of ginger, has instructed his lawyer to settle his case as promptly as possible and for what he can get, giving his reason that he knows of so many cases resulting in death from drinking this firm's preparations that if the knowledge of the suits becomes public there will be so many of them that the firm will be bankrupt and that nobody will get anything. So far as I know, one firm only, in Baltimore, has been guilty of using methyl alcohol in its preparations. Four suits for large amounts have been entered against this firm.

DR. EDWARD JACKSON, Denver—I have seen only two of these cases, and both at a very late stage: Dr. Thompson's case, and one that I recently reported. The clinical history though, and the symptom picture are now so perfectly distinct and characteristic that I think there could be very little question in an individual case as to the diagnosis. I know of no other condition quite similar to it. I think that disturbance of the circulation that has been referred to in connection with the other symptoms, might be of significance when we compare this affection with that produced by quinin. Quinin blindness usually does not come on immediately, but rapidly after the other symptoms have subsided, and there is great disturbance of the circulation.

Experiments point also to the essential likeness of the lesions in the two conditions. Dr. Friedenwald stated his side of the case as to the lesion probably being primarily in the retina very modestly. Uthoff reported that all the cases of toxic amblyopia examined showed changes in the optic nerve. But that they were all very old cases, and there are few conditions of such long standing where the microscope will throw any light upon the original lesion. On the other hand, all of the experimental work indicates that the retina is affected long before any signs appear in the optic nerve. As regards the cases Dr. Ray reported, it seems to me they also confirm the view that it was originally a retinal lesion. In the case he saw early there was some change in the retina, some noticeable edema he said. I remember also a case afterward reported by Dr. G. M. Gould at the First Pan-American Congress, as one of hereditary optic atrophy, in which I saw early not only a haziness of the retina, but some retinal hemorrhages. We must remember that the nutrition of the retina is closely allied to the nutrition of the nerve fibers; and it seems not improbable that there may occur both a retinal lesion, and in certain cases a retrobulbar neuritis. But the latter is probably secondary to the changes produced in the ganglion cells.

DR. R. W. MILLER, Los Angeles—I have had no opportunity of observing any pronounced case of blindness due to methyl alcohol, but recall a case that is interesting in this connection occurring during an accouchement period. The nurse, by mistake, used wood alcohol for bathing, instead of the product made from grain. The entire quantity used was six or eight ounces during a period of three or four days, grain alcohol having been used for previous baths. The fact was not noted until the nurse had finished her duties and gone home. The

first thing that attracted attention was an intense dermatitis. The patient experienced some nausea and anorexia, and slight impairment of vision. About ten days after the baths, she mentioned the dimness of vision, at which time the aid of the ophthalmoscope was invoked. No pronounced fundus changes were noted, although the discs appeared slightly paler than normal. Whether this apparent pallor was due to the action of the alcohol would seem somewhat doubtful. The fact that wood alcohol is not absorbed freely by the skin doubtless saved the patient's eyes from the usual pronounced toxic effect. It seems to me that in all cases in which wood alcohol or "Columbian spirits" is sold or dispensed, there should be a statute requiring that a poison label be placed upon the bottle or other container used.

THE INDICATIONS FOR OPERATION IN CALCULOUS NEPHRITIS AND URETERITIS.*

CHARLES LESTER LEONARD, A.M., M.D.
PHILADELPHIA.

Recent advances in the diagnosis of calculus conditions of the kidneys and ureters show that more than half the calculi that originate in the kidneys pass into the ureters before they occasion sufficient symptoms to make their presence known. This increased frequency of ureteral calculi, which a more accurate method of diagnosis has shown, and the numerous small calculi that are passed with but slight symptoms, make it probable that many such calculi remain throughout life in the urinary tract, neither producing notable symptoms, nor interfering with the function of the kidneys.

Although these calculi may remain quiescent in the ureter and give rise to no functional derangement, they may, on the contrary, entirely destroy the function of one kidney without the recognition of the fact by the patient. The onset of calculous anuria, especially unilateral anuria, so closely mimics in symptomatology the process of recovery, that the integrity of the kidney and ureter, after an attack of renal disturbance, could not be assured without operation, or, at least, the determination of the persistence of a bilateral urinary flow. Operation under such circumstances was imperative to exclude calculi and to guarantee the functional efficiency of the kidney and ureter. Delay without the determination of the absence or exact position and size of the calculi placed the patient in very serious danger of the loss of one kidney and left the diagnosis incomplete with no guarantee for the future.

It is the Röntgen method of diagnosis that has shown the greater frequency of ureteral calculi. Their detection does not, however, constitute an indication for operation. The increased ratio of ureteral to renal calculi is due to their detection and recognition. They must have existed in the same relative proportion previously. The absence of symptoms, that would lead to their recognition, shows how tolerant the ureters must be. It shows that these calculi may be allowed to remain in the ureter, under certain conditions, without grave danger. It therefore sanctions a conservative method of treatment, when that method is rendered safe by accurate knowledge of the condition that is present. The accuracy and detail afforded by the Röntgen method of diagnosis form this safeguard and the rational basis for a differentiation between the cases demanding immediate operation, and those in which an expectant conservatism under strict supervision will often result in the passage of a calculus and complete recovery. It makes it rational to leave to natural methods, what has been recognized as possible for nature to accomplish without injuring the kidney.

The differentiation between the cases that demand immediate operation and those in which a conservative, expectant line of treatment should be pursued, is based upon the results of the Röntgen method of diagnosis. The position and size of the calculi are determined by it, and when taken in conjunction with the symptomatology, furnish accurate data upon which the indications for operation can be based.

The accuracy of the Röntgen method of diagnosis has been demonstrated by the confirmed diagnoses in 165 cases which the author has examined by this method. The negative diagnoses have been found to be as accurate as the positive. The method, when properly employed, is so nearly absolute in its accuracy that its findings are safe data upon which to base operative procedures. Calculi, both multiple and single, bilateral and unilateral, have been found in 48 cases, while, contrary to all previous statistics, over 50 per cent. of the calculi have been found in the ureter. This of itself attests the accuracy of this method.

The wisdom of adopting an expectant, conservative line of treatment in appropriate cases where small calculi are found in the ureter has been shown by the passage of minute calculi, *per vias naturales,* in 3 (now 9) cases where this course has been advised and followed, and in 4 other cases, in which calculi that had been detected were passed before the meditated operation was performed.

The symptoms that should suggest this line of treatment in cases where small calculi have been located in the ureters are: a fairly constant dull ache in the lumbar region or along the line of the ureters, with recent and repeated attacks of more acute pain, with or without microscopic evidences in the urine of the presence and recent progression of a calculus. If the Röntgen picture also shows the shadow of an enlarged hydro- or pyonephrotic kidney, and tenderness can be elicited over the kidney and along the line of the ureter, they make more probable the subsequent passage of the calculus.

The dull, constant ache in the lumbar region, and, if detected, the shadow of the hydronephrotic kidney, can be considered as indicating the presence of functional activity in the kidney and of a *vis a tergo* that will eventually push the calculus through the ureter. The shadow of an enlarged kidney is also confirmatory evidence of the blocking of the ureter. The recent and repeated acute exacerbations of pain in the line of the ureter mark the steps in the progression of the calculus, and promise future attacks that will end in its expulsion. They are the results of the overdistention of the kidney and ureter, while the hydronephrosis is of the "flush tank" variety, the amount of urine fluctuating from time to time as the calculus is pushed along, or the dilation of the ureter permits the urine to pass it. The fluctuating size of the kidney often leads to the diagnosis of a floating kidney, as the change in size is mistaken for a change in position.

These symptoms, in conjunction with the localization of a small calculus or calculi in the male ureters by the Röntgen method, are sufficient indications for adopting a conservative, expectant course of treatment. They sanction a delay, since they furnish absolute knowledge regarding the position of the calculus, so that any urgent symptom can be met by immediate operation upon a

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

lesion that has already been determined. During such expectant treatment the condition of the kidney must be carefully watched, by frequent urinalyses and quantitative estimations of the amount of urea.

The employment of all exploratory instruments in the male where there is no infection, is to be avoided. The segregator, the cystoscope, the vesical sound and the ureteral catheter are all valuable instruments in diagnosis, but their employment in aseptic cases is a question that is still *sub judice*.

Urinalysis can be considered only as giving confirmatory evidence. A normal urine is not incompatible with the presence of a calculus. A number of cases examined by the author and found to be subjects of calculi have had urines that were normal, while in others the slight amount of albumin present could have been considered hardly more than a physiologic variation. In others the negative diagnosis by the Röntgen method was proved by operation to be correct, and yet the urine showed marked morphologic changes.

Although this method of treatment is applicable to the female, the indications in these cases are not quite as definite. The ureters are more accessible in the female, and comparatively simple operations often hasten the passage of the calculi. Recent cases have shown that the Röntgen examination is capable of detecting, not only minute calculi in the pelvic portions of the ureters, but also phleboliths in the venus plexus of the broad ligament, in the veins of the vaginal wall, and in other pelvic veins. In one case, a phlebolith was found in the vaginal wall, in the second, 8 were found, as the operation showed, in the veins of the broad ligament. Although these phleboliths can be differentiated in most cases from ureteral calculi by their position and more general distribution, cases will occur in which the differentiation will be difficult. In such cases the expectant treatment may lead to the destruction of a kidney as the result of a complete unilateral anuria from the impaction of a calculus and the supposition that it is a phlebolith. In such cases the passage of urine from the ureter of the suspected side should be demonstrated by a cystoscopic examination, while the differential diagnosis can be made by using the wax-tipped ureteral catheter. The differentiation is, however, already made, and the presence of a calculus in the ureter assured, if, in addition to its shadow, the skiagraph shows an enlarged or hydro- or pyo-nephrotic kidney on that side.

The expectant treatment can be carried out as rationally and safely in the female as in the male. The indications for immediate operation are, however, greater, as there are simple and safe operations that will in the majority of cases hasten the passage of the calculus. This is more especially true of cases where suppuration exists, and as a consequence the danger of infecting the ureters can be neglected.

In the female, therefore, the presence of infection should be considered as an indication for operative procedures, or the presence of a calculus or multiple calculi, so situated that it is improbable that they will be passed *per viam naturalem*. Complete or unilateral anuria is, of course, a self-evident indication for immediate operation.

In the male the indications for operation are any form of anuria or threatened anuria, or the detection of calculi that are too large to pass, accompanied by symptoms that indicate serious injury to the kidney. The presence of suppuration and small calculi in the ureter are not necessarily indications for operation in the male. The gravity of the operative intervention should be carefully considered, especially where infection is already present. In many such cases it is possible to control the suppurative process by the administration of urotropin or some other urinary antiseptic, until the small calculi have passed. The graver risk of operation may be avoided, and, if operation becomes necessary, the patient will be in a better condition. The presence of multiple calculi does not always indicate operation. A patient recently examined by the author was found to have 6 calculi in the right ureter, just above the bladder. The symptomatology pointed altogether to a vesical calculus. The bladder had previously been explored, but no calculi found. Subsequent to the Röntgen examination the patient passed 2 of the calculi.

Besides the influence which this new method of examination has exerted upon the indications for operation, its accuracy has led to modifications in operative procedures. The field of operation has been limited, and the necessity for exploratory incisions into apparently healthy kidneys in the search for calculi has been obviated. Undoubtedly exploratory operations are valuable, and as necessary in many cases now as formerly, but the actual incision into the kidney is now only justified by the previous detection of a calculus by the Röntgen method, or some macroscopic pathologic lesion.

During the operation for the removal of a renal calculus, the necessary amount of trauma has been minimized. The calculus can usually be located in one or other of the calyces, or in the pelvis of the kidney. The necessary incision can thus be made directly upon the calculus and of just sufficient size for its removal. There is no longer need of splitting the kidney from pole to pole, or for diligent or prolonged search. The diagnosis is complete. The removal of the 1 or more calculi shown in the skiagraph assures the completeness of the operation and renders further search and the resulting trauma unnecessary. The danger that menaced the patient when a nephrectomy was necessary on account of calculus, or of any other form of nephritis, because the other kidney might be involved, is avoided, because all calculi in both kidneys and ureters can be detected or excluded. The hydronephrotic kidney, resulting from the blocking of the ureter by a calculus impacted at the pelvic brim, is relieved by an operation directly upon the ureter without opening and exploring the kidney and running the risk of a urinary fistula.

The operations for these ureteral calculi are direct, without the lumbar incision carried downward when the sound introduced through the kidney chanced to detect a calculus, or the obvious blocking of the ureter made it necessary to determine the cause.

Ureterolithotomy has been successfully performed in a number of cases in which the author has detected calculi in the ureters. It can be either transperitoneal, retroperitoneal, transcystic, after a suprapubic cystotomy, or the ureter may be opened through vaginal vault.

The precise localization of calculi in the ureters has rendered available, especially in the female, methods of operating directly through the ureters that were previously restricted to those cases in which it was possible to determine the presence of calculi in the ureter by digital examination, or by the employment of Kelly's wax-tipped catheters.

These methods consist in washing the calculi out by passing a ureteral catheter above them, by dilating the ureter with suitable conical bougies, and by crushing. All of these methods have served to dislodge small calculi. In addition may be mentioned massage or the

crushing of calculi situated over the pelvic bones, in suitable cases, where they can be reached.

All of these intraureteral methods may be employed as well in the male by a modification recently suggested.[1] The introduction of any of these instruments into the male ureters, after their passage through the urethra, is secured by guiding them into the ureteral orifices by an instrument or finger introduced through a suprapubic cystotomy wound. If these measures are not successful, the wound may be utilized for a transcystic ureterolithotomy.

One of the gravest problems of renal surgery is the determination of which kidney or ureter to operate upon and at what point, in cases of complete and sudden anuria. The necessity for immediate operation is urgent, delay is fatal, so too is operation upon the wrong kidney in many cases. The symptoms are often too misleading or absent to be of value. The previous history is unreliable. The value in such case, if due to calculus impaction, of the Röntgen examination, is readily appreciated. The calculus is detected and the operative procedure directed to the exact lesion. If the outlines of the kidneys can be shown, as is possible in most cases the enlargement of one or other kidney aids in determining which to operate upon first.

Before any operative procedure for the removal of a small calculus, detected by the Röntgen method, is undertaken, a thorough examination of the bladder with a Bigelow's evacuator should be made, with the patient under the influence of an anesthetic. This is essential, because such small calculi are liable to pass into the bladder between the time of their detection and the time of operation. The relaxation resulting from the anesthesia may also hasten their passage. The examination should be repeated at the close of the operation, as such small calculi can be crushed or pushed into the bladder during the manipulations of the operation.

The effect of the Röntgen method of examination upon the indications for, and methods of operating in cases of suspected renal or ureteral calculus have been very marked. The precision attained by this method has rendered a conservative method of treatment safe and rational where it would have been previously bad surgery. It differentiates between those cases that will recover under medical treatment, where calculi have been suspected, and those where the patient's safety depends upon immediate operative intervention. Small calculi which it shows are favorably situated, may be allowed to remain, to pass by nature's methods in cases where the other conditions justify such a course of treatment. The risk involved in the delay has been rendered less grave than the operative risks in many of these cases. The field of operation has been localized to the exact region of the lesion, and the operative trauma reduced to a minimum, as the calculi can be removed through smaller incisions without the necessity of further explorations and yet the completeness of the operation is assured. The possible presence of calculi in other portions of the urinary tract is eliminated as a complication of all renal operations. In exploratory operations, unless a calculus has been detected, incision into the substance of the kidney is contraindicated, unless for other obvious pathologic lesions.

ACUTE CHOLECYSTITIS AND CHOLANGITIS AS A COMPLICATION OF GALLSTONES.*

DANIEL N. EISENDRATH, M.D.

Professor of Clinical Anatomy, College of Physicians and Surgeons: Attending Surgeon Cook County Hospital.

CHICAGO.

In his treatise on gallstones Hans Kehr, whose experience in this special field has been such a rich and varied one, says: "Almost every case of cholelithiasis brings surprises of a remarkable sort. The pathological anatomy of this disease forms the foundation for its special diagnosis and treatment. Without an exact comprehension of the pathology, we can neither make a good diagnosis nor initiate a rational treatment." Stimulated by these words, it will be my purpose to add a contribution rather to the surgical pathology of this subject than to its treatment. The case which I desire to report, and which I will discuss in detail later, was one of the surprises of which Kehr speaks. It is, in brief, that of a girl 17 years of age, who was operated upon for gallstones, and purulent cholecystitis, in which the colon bacilli were found in pure culture, and who died three days after the operation, with symptoms of cholemia, whose liver showed evidences of a diffuse hepatitis and non-suppurative cholangitis, which undoubtedly disturbed the hepatic function to such an extent as to cause death. The history, in detail, is as follows:

J. R., aged 17, single, tin-polisher by occupation, was admitted to the service of Dr. Louis A. Greensfelder, in the Michael Reese Hospital, on Aug. 12, 1899. No history of previous illnesses. Family history negative. For the four weeks prior to admission she had been complaining of a pain in the lower posterior part of the chest. She had not felt as strong as usual, but not ill enough to remain in bed. Three days before admission, this pain became suddenly more severe, and moved around the right side of the chest to the right hypochondrium, in addition to its being felt in the back. Since this attack she had had fever, vomiting and constant pain, the latter increased by each respiratory movement. Bowels constipated. No appetite. The examination revealed a slight jaundice of the scleræ. The entire right hypochondriac and lumbar regions showed rigidity of the abdominal walls, and great sensitiveness to pressure, being most intense over the region of the gall-bladder. At this point one could feel a firm mass, about the size of an outstretched adult hand, not movable, and very sensitive. A diagnosis of gallstones was made.

On Aug. 14, 1899, Dr. Greensfelder made an incision along the right border of the rectus. Upon opening the peritoneal cavity, the tense and distended gall-bladder was exposed directly beneath the line of incision. Its surface was smooth and there were no adhesions. The serosa of the gall-bladder was stitched to the parietal peritoneum, and the wound cavity packed with gauze.

Aug. 16, 1899. The patient was again anesthetized (chloroform used in both operations). After the adhesions between the gall-bladder and abdominal wall were found to be firm, the exposed portion of the former was incised, and a quantity of glairy, clear fluid and pus escaped. With a forceps six faceted (mixed cholesterin and pigment) calculi were removed, and drainage tube inserted after palpating and sounding for other calculi in vain. At the time of admission (August 14) the patient's temperature was 100.4, pulse 120. Shortly after she had a soft, light yellowish, bowel movement. The following day her fever rose to 102. The examination of the urine showed the absence of sugar and albumin, and of any renal elements. Just before the first operation a twenty-four hour specimen of urine showed 2.1 per cent. of urea;

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

otherwise negative. After the operation her temperature remained 101; she passed eighteen ounces of urine with a small amount of albumin, and 2.6 per cent. of urea, and vomited only once. After the second operation (when gall-bladder was opened) the temperature still remained 101 to 102 during the first twenty-four hours. She was very restless, and passed a smaller quantity of urine. On August 18 she had a good bowel movement, and expelled flatus freely. Up to 3 p. m. her temperature varied from 101.4 to 102.4. Suddenly it rose at 3 p. m. to 103.2, pulse 128. Some twitching of the muscles of the face was observed. She then became wildly delirious, and later unconscious. A slight general icteric hue, which had been noted on the previous day (17th), now became very marked. At 5 a. m. on the 19th her temperature had risen to 105.4 (rectal), pulse 160; at 6:30 to 107.4, pulse 180, and just before death (at 7:35 a. m.) it rose to 108.2, pulse too rapid to be counted. In the twelve hours prior to death the prominent symptoms were twitchings, first of face, then of entire body, restlessness, delirium, rapidly increasing jaundice, decreased quantity of urine, high temperature (to 108.2), and pulse (180), and marked dyspnea. The abdomen was never at any time tense or tympanitic. Bacteriological exam-

(Low power.)

ination of the pus taken directly from the gall-bladder at the time it was opened, on August 16, showed the presence of the colon bacillus alone in pure culture.

The autopsy was conducted by the writer about three hours after death. Unfortunately, permission to perform a complete autopsy could not be obtained, so that we were obliged to confine the examination to the immediate vicinity of the wound. There were no signs of reaction about the latter. The gall-bladder was found adherent to the edges of the wound in the abdominal wall. After separation of the adhesions, inspection of the peritoneum covering the intestines, liver and parietes showed no evidences of any infection. It was smooth and shining. [The incision in the gall-bladder was one and one-half inches long, and the entire length of the viscus five and one-half inches. Its diameter at the widest portion one and three-fourths inches. The wall was greatly thickened, three-fourths of an inch.] The mucosa showed evidences of an intense inflammation, being covered by a greenish layer of mucus and pus. There was marked hyperemia and some scattered hemorrhages. At the neck of the gall-bladder, blocking the orifice of the cystic duct, and lying in a pouch-like diverticulum, was a gallstone the size of a small marble, separated from the remainder of the gall-bladder by a fold of mucous membrane. The cystic duct was filled with clear mucus, the hepatic and common ducts showed no changes. Their lumina were not increased. There were no evidences of any pressure having been exerted by the stone which had remained upon any of the bile ducts. The liver was somewhat enlarged, fairly firm. The cut surface was uniformly yellow; the lobules distinctly marked, each surrounded by a hyperemic zone. Cultures made from inoculations taken from the surface of the liver showed the colon bacillus in pure culture. Microscopically, sections of the liver stained with various solutions showed best of all in those stained with dilute fuchsin, a remarkable picture (see Figs. 1 and 2). Under low power one could see that only the peripheral zone of each liver acinus took the stains, the contrast

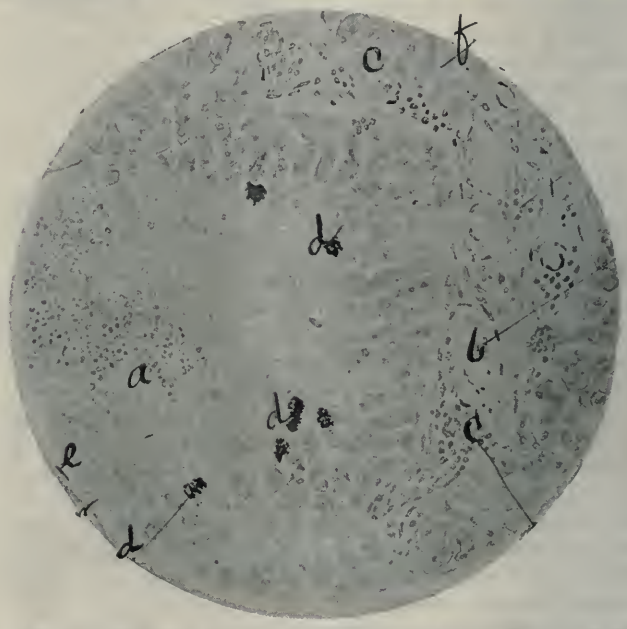

Fig. 2.—Section of liver, stained with methylene blue, showing necrosis of parenchyma, due to colon bacillus; cholangitis complicating gallstone and purulent cholecystitis. *b*, Interlobular bile vessel; *c*, newly formed connective tissue and round-celled infiltration around interlobular bile vessel; *d*, bile pigment; *e*, necrotic liver cells showing nuclear fragmentation; *f*, still preserved cells in periphery of acinus. (High power.)

between it and the lack of color of the remainder being very striking. Under a higher power one could see that there had been an extensive necrosis of the liver cells in two-thirds of each acinus, with marked nuclear fragmentation, etc. Around the interlobular bile vessels there were evidences of proliferative inflammation, and some round-celled infiltration between the columns of still living liver cells in the periphery of the lobule. The latter were loaded with bile pigment. We have thus extensive parenchymatous changes involving over two-thirds of each acinus, and of a necrotic nature. Few of the cells take the stains. In addition there is a well-marked cholangitis of the finest bile vessels.

In reflecting upon this interesting case, the questions which arise are: Why should a patient die with symptoms of cholemia, or, as it is now more properly called, hepatargy, i. e., liver inactivity, whose only apparent complaint had been gallstones, complicated by a purulent cholecystitis? Before proceeding to answer these questions permit me to briefly review some of our knowledge

of the pathology of gallstone disease, in order that we may profit by our deductions.

1. Do the bile passages normally contain micro-organisms? In healthy animals Netter, Naunyn, Leubuscher, Gilbert and Girode found the bile free from micro-organisms. This is especially true for the bile in the gall-bladder, cystic and hepatic ducts; not so for that in the common ducts. On the other hand, Ehret and Stolz found that in a considerable percentage of the cases when bile was taken under all precautions from the gall-bladder of healthy guinea-pigs, dogs and cows, the bile contains micro-organisms. Yet they found that these were not present in sufficient number to cause a peritonitis.

In human beings, Fraenkel and Krause examined the bile in 130 cases at autopsy, and found it sterile in 105. In 11 cases of cholelithiasis examined during life it was sterile in 5. Mieczkowski made cultures from the bile of 15 persons during life. He obtained the bile during laparotomy by aspiration of the gall-bladder. It was found sterile in all cases. In 23 cases of gallstones operated upon by Mikulicz, the bile contained organisms 18 times; only 5 were sterile. The colon bacillus predominated, occasionally associated with the staphylococci and streptococci. He stated that we must regard every case of gallstones as infected. The micro-organisms may be very virulent and cause peritonitis, or they may be less virulent and be absorbed by the peritoneum. Miyake found micro-organisms in only one dog in 55 dogs and 21 rabbies whose bile he examined. From these various observations, made upon animals and human beings, both during life and at autopsy, we can conclude that in the majority of cases bile is sterile under normal conditions. This holds for the entire bile passages, with the exception of the common duct, close to the duodenum, where many investigators have found micro-organisms even when there is no obstruction to the flow of bile.

2. The next question which interests us is, whether bile acts as a bactericide or whether micro-organisms find it a good culture medium. Dominici and Rodet found that the organisms which cause infections of the bile passages thrive in bile.

Maly and Emich, Leubuscher, Röhman, Bates, Fraenkel and Krause, and Mieczkowski observed that both typhoid and colon bacilli develop well but slowly in human bile. If the bile is thick, it especially favors the growth of colon bacilli.

Ehret and Stolz maintain as the result of their experiments that fresh non-sterilized bile has bactericidal properties, confirming the observations of Mosse, and finding that it acts as a poor culture medium.

Mignot and Miyake found that the colon bacillus lives for many months in the gall-bladder. It decreases in virulence, but regains it again readily. Miyake found that bacteria like typhoid and colon bacilli, streptococci and staphylococci, which are usually normally present in the intestine, develop either very well or moderately well in the bile. He injected bacteria into the gall-bladder; they could be found 10 to 214 days later in pure culture, all other organs being sterile.

Talma, the latest writer on this subject, states that the bile acts mildly toward the colon bacillus as a bactericide, but much more strongly toward the diphtheria and typhoid bacilli. In the majority of cases the bile acts as a poor culture medium for the colon bacillus. The bactericidal action depends more upon the secretion of the gall-bladder than that of the bile ducts. There are many cases reported where living typhoid bacilli (Fütterer, Lauriac, etc.), were found in the gall-bladder months and years after an attack of the disease. Altogether we may conclude that bile contains a substance which inhibits the growth of the majority of colon and typhoid bacilli. The number of organisms has great influence upon their fate. The epithelium of the bile passages and the liver cells resist infection greatly. Bile acts as a poor culture medium.

3. The next question which we must try to answer is: How and when does infection of the bile passages occur?

This may occur either through the blood (descending or hematogenous), or be an ascending one along the common duct from the duodenum. The latter is far more frequent clinically. The hematogenous variety of infection through the systemic circulation undoubtedly is possible, as in typhoid, but it is comparatively rare. A number of experiments have been made by injecting large quantities of bacteria into the general circulation (Miyake, Cushing, Guarneri, Queri and Fütterer), but so long as there is no obstruction to the flow of bile, which might cause stagnation, the liver is able

Fig 3.—A, necrotic liver cells; B, cells in periphery of acinus, still healthy; C, newly-formed inflammatory tissue around interlobular bile duct; D, interlobular bile duct. (Low power.)

to excrete a large number of organisms through the bile.

Ferraresi and Guarneri found this to be true for the glanders bacillus; Corrado, Nicati, Oemler, Strauss and Chamberland, Oreste, Pernice and Alessi, Bernabei proved it for staphylococci and pneumococci; Friedlaender, anthrax, cholera and typhoid bacilli. Blachstein, Letienne, Biedl and Kraus, and Menzel proved it for streptococci and colon bacilli.

The ascending variety, where the bacteria invade the liver and gall-bladder along the bile ducts, is unquestionably the most frequent. When the common duct is ligated above the ampulla, the same organisms are found inside of a few days in the liver and bile which are present in the duodenum and in that portion of the common duct distal to the ligature (Homan). This was found true for typhoid and colon bacilli. When these organisms were injected into the common duct below the point of ligation, they found their way very rapidly past the ligature into the liver. The bile which is stagnant above the obstruction (ligature) offers a favorable medium for the bacteria. Infection, with virulent material, when the flow of bile is not interfered with, is without serious consequences.

Even when the common duct is ligated between two ligatures (Ehret and Stolz), organisms multiply rapidly in the bile ducts above the point for a few days, but gradually disappear as the result of the bactericidal action of the stagnant bile. Aseptic foreign bodies introduced into the gall-bladder, on account of interfering with the normal muscular action of the organ, greatly favor the growth of bacteria. Under such circumstances Ehret and Stolz found a great increase in organisms from time to time. When the normal gall-bladder not containing any stones contracts, it can empty its secretion unhindered into the intestine. When the bladder can not contract in a normal manner, on account of the stones it contains, a certain amount of bile remains stagnant between the foreign bodies, and favors the growth of bacteria. Of course, foreign bodies may lie during an entire lifetime in the gall-bladder and never give rise to symptoms until the bile becomes infected, when the typical gallstone colic occurs. The frequency with which cholecystitis and cholangitis occur during typhoid is well recognized now as the result of a descending infection. We are now able to state from

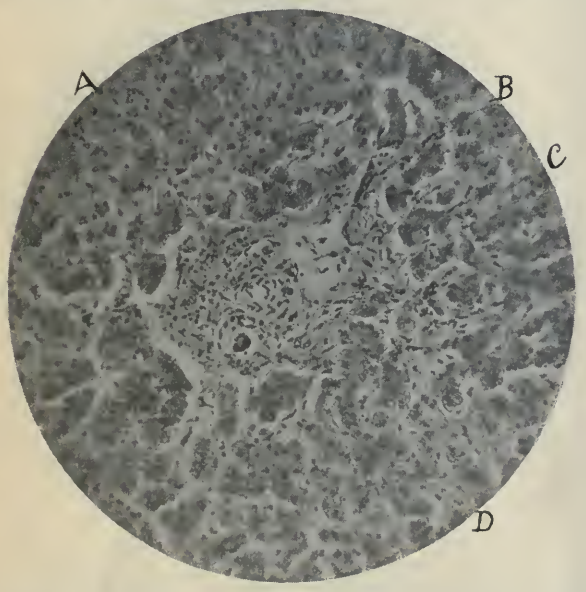

Fig. 4.—A, necrotic liver cells; B, cells in periphery of acinus, still healthy; C, newly-formed inflammatory tissue around interlobular bile duct; D, interlobular bile duct. (High power.)

experiments made by a number of reliable observers that any interference with the contractility of the gall-bladder musculature, or the presence of foreign bodies in the gall-bladder, or ligating the common duct, causes a marked increase in the number of micro-organisms in the bile passages. The ordinary infection in gallstones is almost invariably an ascending one, along the common into the cystic and hepatic ducts.

4. The next question of interest in this connection is: What is the relation between infection and gallstones, and what is the effect of infection of the bile passages (cholecystitis and cholangitis) upon the liver parenchyma?

Thermal, chemical or mechanical irritation of the gall-bladder, simple stagnation of the bile, do not produce gallstones, according to Miyake (whose experimental work on the artificial production of gallstones deserves the highest praise). When sterile foreign bodies are introduced into the gall-bladder there is a considerable increase in bacteria, and some incrustation of the bodies with a substance resembling gallstones. But when the bile is rendered stagnant (partially obstructing the cystic duct), and a virulent culture of colon bacilli injected into the gall-bladder, Miyake found in two animals typical gallstones, one year and ten months later, respectively.

Of prime importance in the formation of stones, then, is infection, usually with the colon or typhoid bacillus. These infective agents set up a catarrh of the gall-bladder and the bile ducts, and when the nuclei of the stones, which most frequently consist of masses of epithelium and fat drops, are allowed to remain in the gall-bladder, through some cause which favors bile stagnation, gallstones are formed. We thus have a complete confirmation of the theories of Naunyn.

When colon or typhoid bacilli are injected into the gall-bladder in small number (Talma), they soon find their way along the bile ducts into the liver, and cause extensive changes in the parenchyma and in the gall-bladder, exactly similar to those which are present in the case I have reported, namely, evidences of severe cholecystitis, necrosis of liver cells in the central portions of each lobule, and interstitial changes along the interlobular vessels.

Our observations of infection of the bile passages in the human beings has been confirmatory in every detail

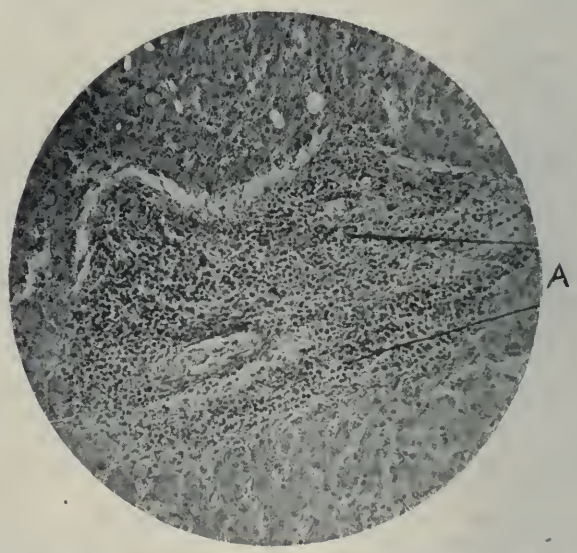

Fig. 5.—A, Extensive round-celled (inflammatory) infiltration around interlobular bile vessel. (High power.)

of the work on animals. The latter has assisted us greatly in comprehending the former. Gallstones may remain in the gall-bladder for years without giving rise to the least suspicion of their presence. When an infection has been added, an inflammation of the gall-bladder is set up (cholecystitis), and the patient has a typical gallstone colic. The stones, unless they are very small, are rarely expelled, but are driven toward the neck of the gall-bladder. The serous effusion frequently changes to a purulent; in other words, there is simply a question of the degree of infection. Upon it depends the fact whether we have a serous, purulent or gangrenous cholecystitis. In 50 cases examined bacteriologically at the time of operation, Petersen found the colon bacillus either alone or associated with ordinary pus cocci in 46 cases. They were present even when the bile was clear and when there were no visible changes in the gall-bladder. The serous variety frequently subsides, but in the purulent the organisms may spread along the bile ducts into the liver, producing either a purulent or non-purulent cholangitis. The latter process is especially likely to occur when any cause for bile stagnation, for exam-

ple, stone in common duct, exists. The clinical picture of the cholecystitis usually predominates, so that the cholangitis, with its grave influences upon the liver parenchyma, is masked. The course of a cholangitis seems to be most acute with virulent colon bacilli, more chronic with staphylococci and streptococci (Quincke).

The symptoms of cholangitis complicating gallstones are that after one or more attacks of colic there is a more or less marked tendency to fever, icteric hue and dull pain in the liver region. The fever may be of the type described first by Charcot, and frequently misleadingly called hepatic intermittent fever. The more or less regular recurrences of chill, fever and sweat resemble malaria greatly. In this variety there may be multiple abscesses in the liver (purulent cholangitis). Later the clinical picture may be that of a septicopyemia, with endocarditis, etc. Pick noted during the attack a marked decrease in excretion of urea and an increased leucocytosis.

Symptoms of Cholecystitis.—This, as stated above, may be either serous, purulent or gangrenous. There is always pain over the gall-bladder, radiating to the shoulder, no icterus, as a rule, no enlargement of the liver. There is usually some fever, especially if there is pus present. It is not of the septic type, as in suppurative cholangitis. Generally a tumor can be felt, but where the process has existed for some time the gall-bladder may shrink so that none can be felt. When present it may be quite movable.

The non-suppurative form of cholangitis complicating gallstones is not characterized by as marked emaciation, rise of temperature or septic symptoms. The course is more prolonged and there is not apt to be much jaundice. Cholangitis is not so important of itself as that its sequelæ, abscess formation and parenchymatous changes in the liver, may be very serious.

The prognosis of cholangitis and cholecystitis depends upon the cause. Both are rarely found without gallstones. Typhoidal cholecystitis and cholangitis usually subside without any complications save adhesions of gall-bladder to adjacent organs. The appearance of these two complications in the course of gallstones should influence our prognosis greatly. The grave anatomic changes in the gall-bladder and larger bile ducts, such as adhesions, ulceration and greatly thickened walls, may cause symptoms sometimes classed as pseudo-relapse symptoms for years after an operation. The prognosis of the suppurative type of cholangitis is, of course, extremely bad. That of the non-suppurative is shown forcibly in the case I have reported above, and we should always be prepared for surprises of this kind. The necrosis of liver parenchyma as a result of the biliary infection results, first, in paralyzing the ability of the liver cells to get rid of bacteria and toxic products of the body, and, secondly, in reducing to a minimum the formation of urea or allied products.

The death of the patient whose history I have given, and the study of whose case has formed the basis of this paper, was undoubtedly due to that condition which was formerly called cholemia. It was given this name because it was thought that the blood contained bile in large amounts. We now know that it is a form of auto-intoxication, due to a lack of functional activity of the liver cells, so that toxic products are retained in the system. Hence, the name hepatargy or liver inactivity has been proposed to designate the group of symptoms chiefly of a nervous character, as in our case. They may develop gradually or suddenly, resembling greatly the symptoms of uremia or diabetic coma. The acute onset probably expressed, according to Quincke, the moment when the already incompetent liver is no longer compensated by the kidney and other organs. These symptoms are delirium, high temperature, muscular twitchings, or even general convulsions. They may be present in a lesser degree in some cases, and entirely disappear. Usually their onset precedes death by a few days. The condition is especially liable to occur when the common duct has been obstructed, so that toxic products can no longer be carried off by the bile. In our case there was no direct closure to be found, but it is well known that a permanent closure of the common duct can be caused by a marked, long-continued dilatation of the gall-bladder, as a result of displacement of the cystic duct by large stones, which are either present in it or in large diverticula. But it is not necessary to ascribe the hepatic intoxication to other causes than a disturbance of the liver cells, as the result of infection.

I believe that there is every reason to ascribe the nervous symptoms shown by our patient to auto-intoxication, or liver inactivity, interfering with the formation of urea and elimination of toxic products and bacteria by the liver cells and bile, and that it is an example of one of the results of infection complicating gallstones. The case teaches, first, that in every case of gallstones we must try to make an exact anatomical and pathological diagnosis, in addition to that of gallstones. Whenever pus is present in the gall-bladder, especially if the symptoms have been acute, our prognosis should be guarded. A purulent cholecystitis is almost invariably accompanied by a cholangitis, which, as in our case, need not be purulent. It may be said that whenever gallstones are accompanied by temperature we should think of a concomitant infection of the intrahepatic bile ducts, with its resultant pernicious influence upon the liver parenchyma. Such a change may cause sudden death through hepatargia.

In order to relieve a cholangitis which might exist in addition to a cholecystitis, it has been proposed, first, by Kehr, to drain the hepatic duct, for in some cases, even though the obstruction in the common duct has been removed, the sepsis continues. I believe that in our case the blocking of the cystic duct through the stone which lay in a diverticulum of the gall-bladder prevented the septic bile from flowing out through the abdominal wound.

In conclusion, I may say that the treatment of an empyema of the gall-bladder complicating gallstones, should never be one of delay. They should not be treated by internal means, but referred to the surgeon as soon as a diagnosis has been made. As soon as a diagnosis of gallstones in general is made, since we know the dangers of infection and carcinoma developing as complications, the surgeon should be consulted and the question of operation considered and in the majority of cases advised.

103 State Street.

Cerebral Syphilis.—Tschisch calls attention to the importance of diagnosing syphilis of the central nervous system when only the vessels are affected. Sclerosis of the vessels is first visible in the anterior branch of the temporal artery as it bifurcates in the temple at the edge of the hair, or 1 or 2 cm. below. Headache and sleeplessness are the earliest and most important of the prodromal symptoms, while vertigo is only rarely observed. All the other familiar symptoms of cerebral syphilis belong to the second period, in which the affection is already past remedy; such as the double vision and modifications in the reflexes.

DISSECTING ABSCESS OF THE ABDOMINAL WALL PRODUCING DEFORMITY SIMULATING POTT'S DISEASE.*

JAMES B. BULLITT, M.D.
LOUISVILLE, KY.

The case which forms the basis of this report presents features which render it of sufficient interest, it is believed, to warrant its presentation to this Section. The patient was a lad of 16, who was taken sick in January, 1900, with a typical attack of typhoid fever. He remained in bed six weeks, when, on getting up after the subsidence of the fever, there was observed a certain amount of inability to raise the left leg in drawing on the trousers. By the middle of May he developed a general antero-posterior curvature of the spine from the sacrum up with a lateral deviation with the convexity to the right side, and at this time was seen by Dr. Ap M. Vance of Louisville. There was some fever at the time, though no record was kept, and there was a certain fulness in the right loin which caused a suspicion of a possible perinephritic abscess. He was put to bed, and when seen six weeks later was found to have improved very much. He had taken on flesh and the fulness in the loin had disappeared, but there was a decided resistance on the right side between the umbilicus and the anterior superior spinous processes of the ilium. This resistance at this time was believed to be due to the matting together of the intestines as a result of localized peritonitis from the typhoid ulceration. It was also considered as possibly due to an appendicitis. At this juncture, in July of 1900, the boy was sent to the country, and after three weeks believed that he was entirely well, as all symptoms had disappeared; but after unusual exertion incident to a long ride and the breaking down of the vehicle, a high fever occurred (105) and great pain was felt under the left costal border. After a few days an abscess pointed at the navel, broke spontaneously and discharged a large quantity of thin pus filled with flaky white particles. When seen by the writer, in January, 1901, about one year after the beginning of the attack of typhoid fever, the patient presented a sinus at the umbilicus which discharged a thin watery pus. He stated that by irrigating the cavity with which this sinus communicated, several pints of water could be retained and then ejected by making pressure over the left side of the abdomen. There was a marked kyphosis, lumbodorsal in character, with a slight lateral deviation, the convexity looking to the right. The kyphosis at this time was not a general antero-posterior curvature, as when first observed eight months before by Dr. Vance, but was a sharper curvature limited to an area of four or five vertebræ. My first impression of the condition was that it was Pott's disease which had developed abscess with final rupture at the umbilicus; but it was found that the vertebral column was entirely flexible for flexion and lateral movements, and that extension of the column was impossible only on account of the thickened, indurated and unyielding condition of the left half of the abdominal wall. Palpation from the umbilicus to the loin on the left side gave the feel to the hand of a board implanted beneath the superficial tissues. It seemed clear that the deviation of the spinal column was due, as when first observed by Dr. Vance, to an effort on the part of the patient to relieve pressure from the abscess in front, and that this position afterwards became accentuated and habitual from the inability of the lad to return his body to an erect posture after the abscess had discharged, because of the thickened and indurated abdominal wall. Unfortunately for the boy, and for this report, the patient has persistently refused any operative relief up to the present time, and continues with the deformity described and with the sinus discharging a thin watery pus at the umbilicus.

Nevertheless, in the light of the experience of others, it is felt entirely justifiable to make a diagnosis in this case of a dissecting abscess of the abdominal wall following and dependent upon typhoid fever. Such abscesses after typhoid fever are uncommon, but have been described by several writers as hereinafter briefly summarized. This case, however, seems to be unusual in the development of a marked deformity leading to the casual diagnosis of Pott's disease of the spine.

It is well known that as a result of typhoid fever certain degenerative changes take place in many structures of the body and amongst others that the voluntary muscular system suffers a degeneration of both a nuclear and a waxy type, as described by Zenker as early as 1864. One result of such degeneration is an occasional rupture of the rectus abdominis muscle.[1]

Further, abscesses may occur within the muscular structures of the abdominal wall without any demonstrable connection with any lesion of the abdominal cavity, as in a most interesting case reported by F. Raymond in *Le Mercredi Medical,* Paris, 1891.[2] In his case, at about the fourth week of typhoid fever, an induration and swelling developed in the abdominal wall below the umbilicus and to both sides of the median line. The patient died about one week thereafter and on autopsy there was found a large pouch containing about two tumblerfuls of pus without any odor. There was no trace of communication with the abdominal cavity, the walls of the abscess cavity being absolutely intact and at the same time infiltrated, edematous and quite hard. Cultures upon various media demonstrated the bacillus of Eberth as being the only micro-organism present.

Other pyogenic organisms have been found in abscesses occurring during the course of typhoid fever and entirely disconnected with the abdominal cavity. It is recognized that such organisms may find a ready portal of entrance into the circulation at the site of the ulcerations resulting from the typhoidal process.[3]

On the other hand, it is readily conceivable that abscesses of the abdominal wall may result from inflammatory processes which have had their inception within the abdominal cavity and have been communicated to the structures of the abdominal wall itself as the result of inflammatory, ulcerative or perforative lesions of the organs contained within the cavity. While a number of such lesions might be mentioned as being possibly responsible for such pathologic conditions of the abdominal wall, there are only two which will be mentioned here, namely, those occurring as the sequelæ of typhoid fever and appendicitis.

Coplin and Beven[4] report a case of an abscess of the abdominal wall which made its appearance ten weeks after recovery from typhoid fever. A hard, painful swelling appeared over the right lower portion of the abdomen, which gradually extended across the linea alba and upward to the umbilicus, at the lower margin of which a small prominence appeared which was resonant on percussion. This was laid freely open and a large amount of offensive gas escaped. The floor of the

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee of the Section: Drs. W. J. Mayo, H. O. Walker and A. J. Ochsner.

cavity was covered with a small amount of pus of a fecal odor. A sinus was discovered leading between the abdominal muscles, but was too tortuous to be followed with the probe. Fecal matter appeared on the dressings afterwards, and continued at intervals for three months. The area of the inflammatory deposit decreased but little during the whole of this time. Other complications developed and the patient finally succumbed to uremia consequent upon a nephritis. The postmortem examination showed that the abscess still existing was mural in location and did not communicate at the time of the postmortem with the intestinal wall or the cavity. There were points of localized peritonitis, evidently old, seated over various points in the intestine and forming adhesions. Upon opening the intestine many of them could be demonstrated as the original seats of typhoid ulcers. There were loops of intestine attached firmly to the abdominal wall immediately at the umbilicus, and, although it could not be demonstrated, it is to be presumed that the primary abscess originated from infection occurring through a perforation.

Dr. Ap M. Vance reports[5] the case of a girl of 9 years who, during the seventh week of typhoid fever, developed an abscess of the abdominal wall which discharged a large amount of pus spontaneously at the umbilicus. Five weeks later an incision was made from the umbilicus to both sides of the median line, discharging a large amount of pus of a very fecal odor. The abdominal wall from the ribs to the ilium had entirely separated from the parietal peritoneum, and this surface constituted the floor of the abscess cavity, which extended from the opening at the umbilicus back to the kidney region on both sides. No point of communication with the bowel could be detected. Recovery followed this free drainage.

Dr. Vance has personally communicated to me a second case of a practically identical kind occurring in a little girl. Recovery likewise occurred in this case after free incision and drainage.

Dr. Michie[6] reports a case of abdominal abscess developing during the fourth week of typhoid fever. Pain, swelling and tenderness appeared below and to the left of the umbilicus. The abscess was opened and drained, the patient making a prompt and complete recovery. The diagnosis was made of abdominal abscess having its origin in a suppurating gland of the mesentery.

George Westby[7] describes a patient of 21 years who was believed to have typhoid fever complicated with peritonitis and passing on to an abscess of the abdominal wall, which pointed to the right of and below the umbilicus. This was incised and three months afterwards apparent healing with closure of the sinus had taken place. A month later, however, the cicatrix gave way and there was an escape of fetid pus which was not fecal, however, at any period of the patient's illness. Efforts to bring about closure of the sinus were unavailing, so it was finally laid open by incision. In the course of laying open the sinus something was cut across which exactly resembled a very small intestine. This was recognized to be the appendix veriformis. As a result of the operation satisfactory healing took place.

It would seem certain in this case that the presence of the appendix in the track of the sinus in every probability bore a causative relationship to the persistence of the sinus; and further, that the original abscess, which is described a perityphlitic, was almost certainly of appendicular origin, whatever may have been the relationship of the alleged typhoid fever to the abscess formation.

Dr. W. W. Keen[8] relates a case which gives the reverse side of the picture. A young man of 17 years, two months after an attack of typhoid fever, developed pain in the right groin, followed by the formation of a soft oval tumor just above Poupart's ligament, and just to the right of the internal ring. It was believed to be a hernia resulting from the rupture of the muscles of the belly wall consequent on the hyaline degeneration following typhoid fever. It was, therefore, decided wise to wait until distinct regeneration of the muscle fibers had occurred before undertaking operation. After a week in bed, however, the tumor was found to be increasing in size and operation was undertaken immediately. Incision quickly opened an abscess with evacuation of 1½ pints of pus which was not fetid nor of any fecal odor. A probe passed upward 15 centimeters almost to the level of the umbilicus. It also passed downward towards the true pelvis, but did not reach it. The fingers introduced into the cavity discovered nothing except the ring through which the abscess had come and a very large cavity beyond. The author's impression was that instead of a hernia he had to deal with a typhoid abscess arising in the connective tissues between the iliac internus muscle and the iliac fascia; or it might have arisen from a perforation of the appendix by typhoid ulcer. Cultures from the scrapings of the abscess cavity demonstrated tubercle bacilli, but no other organisms. This suggested the possibility of a psoas abscess resulting from Pott's disease. Up to this time the man had not been aware of any trouble whatever with his back, and had never suffered any pain in this region; but nevertheless a very careful examination showed unquestionably that he had Pott's disease at the dorso-lumbar junction. All the symptoms were now perfectly explicable. It was evident that a man who had had Pott's disease for a period of time long enough to produce a psoas abscess containing 1½ pints of tubercular pus, had passed through an attack of typhoid fever and a relapse without having any infection in the abscess or the bones from the typhoid bacilli and without aggravating the Pott's disease in the slightest degree, and, indeed, without the patient's ever knowing that he had any disease whatever in the spine. In conclusion I submit the following considerations:

1. Abscesses of the abdominal wall without any connection with the abdominal cavity occur most frequently as a result of typhoid fever and readily heal after incision and drainage.

2. The larger dissecting abscessses of the abdominal wall communicate at their inception with some portion of the intestinal tract, occur most frequently as a sequela of typhoid fever or appendicitis, and result from an adhesion between the parietal peritoneum and a viscus, with perforation of the latter. After rupture such abscesses follow the course of fecal fistula, healing sometimes spontaneously or as a result of incision with drainage only after the communication with the intestine has become obliterated. This obliteration sometimes occurs spontaneously, sometimes must be brought about by operative procedure.

3. A dissecting abscess may produce symptoms and deformity simulating Pott's disease; on the other hand, Pott's disease with abscess appearing after an attack of typhoid fever may be confounded with abscess resulting from the typhoidal process.

DISCUSSION ON PAPERS OF DRS. LEONARD, EISENDRATH AND BULLITT.

Dr. F. D. Smythe, Memphis—I would like to report an interesting case along the line of work that Dr. Leonard has been doing so successfully. The patient, a gentleman 42 years of age, had suffered for two years with intractable cystitis. Examination of urine revealed the presence of pus, streptococci and gonococci, also an abundance of mucus. He was losing flesh rapidly. Suprapubic cystotomy was performed in order to afford him temporary relief. The opening in the bladder was permitted to heal after three weeks' duration. His general condition at this time was very much improved and he left the hospital. Within a few days he again reported with cystitis as bad as before operation. Whereupon an *x*-ray examination was made revealing the right kidney very much enlarged. A diagnosis of pyelitis and probable stone was made. The Roentgen ray did not reveal the presence of stone. Nephrectomy was performed and examination showed numerous abscesses in the kidney, also small cysts with an extensive involvement of the pelvis. Gonococci were found along with other germs by the pathologist. No stone was found in the kidney upon section. This patient suffered but little inconvenience as result of the removal of his kidney. He voided about the same quantity of water after the operation as he had done before and said that he felt as well as before operation with the exception of a slight pain attending the division of the nerves in the lumbar region. After two weeks he left the hospital suffering considerably from dyspnea. Examination revealed a mitral regurgitation of the heart. This was followed rapidly by swelling of the feet, puffiness under the eyes and marked pallor. I gave an unfavorable prognosis and advised him to return to his home in New Orleans, La. He had been the victim of a gonorrheal infection for six years and the trouble with the kidney, in my opinion, was the result of an ascending gonorrheal infection.

We frequently encounter gallstones associated with malaria and not infrequently cholangitis following typhoid fever. We have cholecystitis and afterward the development of gallstones. Gallstones, as a rule, are not attended with jaundice. Jaundice occupies a position rather too prominent as a symptom of cholelithiasis—when, as a matter of fact, it rarely if ever exists unless the common duct is obstructed. In four cases recently operated on where numerous gallstones were found jaundice was never a symptom. In two cases that were operated on that were remarkably jaundiced no gallstones were found. One case of chronic malarial infection with perihepatitis and adhesion of the liver to the peritoneum had almost complete obliteration of the gall-bladder, which was removed. No trouble was experienced afterward so far as the operation was concerned.

In cases of persistent jaundice we should be on the lookout for malignant disease of the pylorus or head of the pancreas. Operation on the gall-bladder is, as a rule, attended with very little risk and jaundice is not a contraindication to surgical operation. The technique of the operation I would suggest as being most satisfactory where the conditions justify the procedure is a complete closure of the bladder after incision of the fundus, removal of the gallstones and thorough cleansing. In all these cases we find a catarrhal condition of the bladder existing, and after removal of the gallstones, I wash out the bladder with nitrate of silver—weak solution—and if the walls are healthy close the incision in the gall-bladder as we would a wound in the intestine. The morbid fear of leakage of bile referred to by most authorities will not occur if the technique is properly carried out. I close the gall-bladder without any fear by running a silk suture through and through near margin of incision, and over this row of sutures put in another of seroserous and have never seen leakage follow the operation. Where the gall-bladder is extensively diseased, pus being present or obstruction of the common duct exists, cholecystostomy is the operation to be preferred, as closure of the bladder under such circumstances should not be expected to be followed by good results.

Dr. G. MacGowan, Los Angeles—I wish to ask Dr. Leonard, and I want him to answer for the benefit of all of us, whether the Roentgen rays do accurately give us, at all times, and under all circumstances, in his experience, a fair shadow picture of a stone existing in the kidney or in the ureter. I wish to ask him further, whether, in the hands of an expert, himself even, the diagnosis has not been made of the presence of stone in the kidney and ureter, operation made and no stone found; or whether the diagnosis of the absence of stone has been made, an operation made by the surgeon, and a stone has been found in the ureter or kidney. I wish to call the attention of the Section, further, to a very serious question in the use of the Roentgen ray. It has been my extreme ill luck to have had under my care two, probably, of the most severe Roentgen ray burns that have ever taken place. One lasted, I think, eight months, another for over a year. In both cases healing finally took place only after thorough excision of all the tissues that presented the appearances of having undergone cell-destruction, and, in addition, the removal of a large area of apparently healthy tissue outside of this. These men became invalids. This led me to commission a lady in Chicago, who does that kind of work, to compile the literature of *x*-ray burns. I was appalled at the number of serious cases reported. I would like the Doctor to tell us whether such dangerous burns do not, sometimes, still occur.

Dr. Baldy says that when the report of the microscopist does not agree with your clinical judgment as to the presence of cancer in the neck of the uterus, remove it anyhow; and I say, when the Roentgen picture does not agree with your clinical judgment as to the presence of a stone in the kidney or ureter, cut anyway. But it is not always safe to cut, because the Roentgen picture shows a shadow, unless it is well defined, and occurs in several pictures, always in the same place. In one of my cases, the picture had been made by a man who was very competent. The screen, before, had shown in the kidney the presence of a dark shadow, and the skiagraph made contained one which my colleague pronounced as unquestionably that of a stone. We held the man under observation for two or three months, and treated him for tuberculosis. The shadow cleared up entirely; none appeared in the second picture, nor could any be seen by the screen.

Dr. J. D. Thomas, Pittsburg, Pa.—A patient, passing pus in his urine, was treated for cystitis, and was examined by me with a cystoscope and searcher. I failed to find a stone. In addition to that he had kidney symptoms. I cut down on the kidney and explored it thoroughly and failed to find a calculus. The wound healed kindly, but after a while he still complained of his bladder trouble and now on examining with the searcher I found a small calculus, which was crushed and passed without the pump, because it was not large enough to require the pump. During the operation on the kidney I think the calculus had been disturbed and passed down the ureter, into the bladder. In another case, with the Harris segregator, I found that in the urine from the right kidney there were pus-cells and blood cells, while the left kidney urine was normal. I had the Roentgen ray used, but as the skiagraph was not returned to me as soon as I expected it, I cut down on the kidney and removed a calculus as large as a peanut. The next day I received the skiagraph, but it did not show it. So I had the stone where the skiagraph did not show a stone. We may be mistaken with our diagnosis in all our methods. I am in favor of the skiagraph. It was possibly the fault of the operator. Another interesting case to me occurred about three or four weeks ago. A patient with symptoms of cystitis had been treated for about three or four years, and, in addition to that, he had pain almost continuously in the lumbar region over the right kidney. I used the Harris segregator and found that the urine apparently all came from the left kidney. There appeared to be no urine from the right kidney. For fear I

might be mistaken in my technic I waited for four or five days and repeated it and found the same conditions. I therefore presumed that the right kidney was so much disorganized that it was doing no work. I cut down on the right kidney and to my surprise found it almost normal. Now, that also demonstrates that one can not always depend on the Harris segregator, although I do think it is a good method for diagnosis in addition to our other methods of diagnosing.

With regard to closure of the gall-bladder after opening it, although I do not do a great deal of work in this line, I have closed the gall-bladder and dropped it into the abdominal cavity, and in one case, where I made a postmortem a month afterward, the patient dying from aneurysm, I found that one could hardly tell that this gall-bladder had been opened. It was closed with catgut, and at this point you could hardly tell whether it was opened or not, and that gall-bladder I presented before this Section two or three years ago. At that time the consensus of opinion was that it was not good treatment to drop it into the abdominal cavity. I believe it to be good practice to close the gall-bladder and drop it into the cavity, unless there is some special reason to attach it to the abdominal walls.

Dr. W. J. Means, Columbus—It seems that some investigators have found the coli bacilli in the bile passages. This could scarcely be said, however, of the typhoid bacillus which is known to be a frequent cause of cholangitis, and consequent biliary calculi. It is a well-established fact that normally the fluids of the body are inhibitory to the growth of bacilli. The bile is no exception to this rule. However, any of the fluids may become culture media under pathological conditions. One of the most interesting points discussed is what leads to the formation of stones in the gall-bladder. Primarily there must be infection. This may be brought about in several ways. Trauma, perhaps, plays an important rôle; changes in the normal conditions of the bile through disease and sedentary habits are another cause. Under these abnormal conditions, bacteria find lodgment and multiply. Clumps may form around which the constituents of the bile form. It has been my contention for some years that gallstones always produce some irritation and are a menace to health and life. The very fact that infection is the starting point presupposes an abnormal condition, and as long as the products of this infection remain there will follow more or less disturbance of the functions of the biliary apparatus. Granting that the symptoms are not pronounced, yet sooner or later an impression is made. It is my further observation that greater familiarity with the pathologic conditions of the biliary apparatus helps us to recognize and locate the origin of heretofore obscure phenomena. I have in mind a case operated a few months ago that illustrates my point. A lady, age 42, multipara, had been an invalid for several years, suffering from abdominal disturbances. A gynecologist looked after the generative organs and removed one ovary and tube. No relief followed. When she came under my care there was tenderness over the abdomen, most marked, however, above the umbilicus and in the region of the ascending colon. Neuralgic pains were frequent and severe in the region of the spleen and left kidney. There were no symptoms nor group of symptoms that pointed to the gall-bladder being the seat of the trouble. An operation for the purpose of making a diagnosis was made. The visceral organs were found healthy, except the gall-bladder; a calculus weighing two drams was found and removed. The patient made a good recovery, and has been free from pain and abdominal tenderness up to this time.

I am fully aware that one case does not establish a rule, but it is an illustration of the extensive trouble that can arise from the presence of a foreign body in the gall-bladder. The classical symptoms of tenderness over the gall-bladder, neuralgic pains extending up to the right shoulder, gastric disturbances and jaundice may be absent or masked by more general symptoms over the abdomen. It is my firm conviction that the teaching that calculi may remain in the gall-bladder for years without producing any disturbances is unscientific and fatal to many patients.

Dr. B. B. Davis, Omaha—Some time ago I examined all the cases of gallstone that came into my hands with an effort to determine what constituted the nucleus. I did not carry it out with sufficient correctness, I suppose, to arrive at any very definite conclusion. In several instances I found the clump of bacteria constituting the nucleus. The colon bacillus, I think, was the chief, and, in one case, the typhoid bacillus. The symptoms of gallstones occur so soon after an attack of typhoid fever that Dr. Cushing has come to the conclusion that in many cases typhoid bacilli clumping constitutes the nucleus around which the stones form. I have come to the conclusion that infection is the primary cause. There is no reason why, after the stones form, that this infection should not clear up so that the symptoms of gallstones pass away and that, again, reinfection takes place. I have been impressed by two or three cases comparatively recently, that it is very important that when we make the diagnosis of gallstones an operation should be advised as soon as possible. In one instance I advised such an operation. There was an attack of cholecystitis and the symptoms were quite alarming for a day or two. The woman arranged to go into the hospital and have the operation on the following day. Next morning she felt better and delayed the operation, living two or three months in comparative health, but all of a sudden was taken with sharp pains and went into a collapse. I was not called in until forty-eight hours after that, and then she was moribund. Upon a postmortem examination being made, we found about a dozen stones in the gall-bladder; one of them with rather a sharp corner had perforated the upper part of the cystic duct and bile flooded the abdominal cavity; the bile was infective, there being a peritonitis already established. I think we should operate in every case, with the idea that the contents of the bladder, whether we have acute cholecystitis or not, may infect the peritoneum. We should wall off just as carefully as if we were doing an appendicitis operation in the presence of pus; because we can not tell at the time in what cases there is an infection. Some have spoken of the so-called "ideal cholecystotomy"—the immediate closure of the gall-bladder. If we could tell in any particular case at the time of operation that there was absolutely no infection, no tendency for the clumping together of bacteria, no tendency for the mucus to form into little balls to act as a nucleus, it would be all right, but I had a sad experience in one case. I felt that I had nothing there except the stones; we had a practically normal gall-bladder; I closed it up. A few months after that she had recurrent symptoms and later she had several stones removed by operation. Since then I have made it a practice and expect to continue this practice of draining the cavity and keeping the drainage tube in until all indication of any infection has passed away.

Dr. W. L. Rodman, Philadelphia—In Philadelphia the accuracy of the *x*-rays in locating stones in the kidney, ureter, and in the bladder, is looked on as a very decided step in advance. We feel that occasionally a mistake may be made as was today mentioned, but it is rare, and while I have not had the privilege of having Dr. Leonard do work for me, I have heard several surgeons say that they have never known him to make a mistake. I have for three years had the services of a very excellent man and have not known him to make a single mistake. He has located very accurately stones in the kidney, ureter and bladder. I was present at one operation where there was seemingly a mistake made by the *x*-rays; at least the operator thought so; it was not a very satisfactory test in my judgment as the outline of the kidney substance was not clear to me; yet the case has been quoted as having been one in which there was a mistake made on account of the wrong interpretation given by the *x*-rays. I myself feel that it is a most valuable aid and one which we should not ignore. I should hesitate to cut into a kidney, unless I was very certain that the clinical signs overweighed the negative evidence furnished by the *x*-rays.

As to the question of burns, I think that has been practically eliminated by improved technic. I have not seen a single burn from *x*-rays in the last two or three years, notwithstanding that it is used two or three times a day in the Medico-Chirurgical Hospital by Dr. Kassabian. I have recently investigated this subject carefully, and wanted to subject my own daughter to a test of this kind, on account of the fact that the dentist

recommended it, because a temporary tooth had not been shed and he was not sure whether there was a permanent tooth in the maxilla, and did not care to sacrifice the tooth until he knew whether the permanent tooth was present and wanted to have an *x*-ray diagnostic photograph made for that purpose. Naturally, I hesitated to do this, but asked Dr. Fox, the ophthalmologist, whom I knew had been using this test on the face. He said: "I have never seen even a conjunctivitis following exposure. I have used it hundreds of times. You can go ahead and I assure you from my own experience and as a personal friend that you will take no risks." So I feel that the risk of burns has been practically eliminated.

DR. C. H. LEMON, Milwaukee—I recall two cases of abscess of the abdominal wall that occurred about two years ago. One case I saw in consultation with Dr. W. H. Earles, of Milwaukee, and the other while I was attending a clinic of Dr. Keen, in Philadelphia. I cite these cases because of their infrequency, and I think they ought to be brought to the attention of the profession. They show us another source than Pott's disease of the spine or abscess following perforation of the intestine as a cause of dissecting abscess of the abdominal wall. These two cases are identical. One was a woman about 55, and the other a negro, I should say about 35. Both cases gave a history of recurring appendicitis. In both cases there was entire absence of jaundice; the possibility of suppuration of the gall-bladder with rupture and dissecting abscess of the abdominal wall was not thought of by any of the gentlemen who examined either of the cases. In Dr. Keen's case the negro had stated to him that the swelling that was present in the abdominal wall was recurrent, that he had had the same swelling before, and it had disappeared. The swelling was in the right groin; it looked exactly like an abscess resulting from appendicitis; it pointed; it was quite prominent and Dr. Keen was perfectly satisfied in his own mind that it was an abscess the result of appendicitis. In our own case—Dr. Earle's—we had the very same experience. Now, gentlemen, in both of these cases when the abscess was opened it was found that it lead directly to the gall-bladder, and in both cases gallstones were turned out as large as the thumb. Dr. Keen laughed at his mistake, as we did also at ours, but in the absence of reports of similar cases, who would not make the same mistake? I have never seen cases similar to these cited in our literature. I thought while we were discussing inflammation of the gall-bladder and dissecting abscess of the abdominal wall that these cases would prove interesting and valuable, as suggesting another source for the formation of pus that appeared as an abscess of the abdominal wall.

DR. JOSEPH C. BLOODGOOD, Baltimore—Let me call your attention to the relation between gallstones and acute and chronic pancreatitis; an important fact which has not been brought out in the papers read this morning. I mention this relation because it is only recently that we have understood it. The literature on gallstones and pancreatitis needs more careful clinical observations. I trust that all who in the future observe cases of acute pancreatitis which have the usual misfortune to go on to autopsy, will have made a careful examination of the gall-bladder and ducts, so that our records will be more accurate in regard to the presence of gallstones in cases of acute hemorrhagic and suppurative pancreatitis. It will also be of importance and interest to have further records of those cases which clinically give typical histories of gallstone colic with and without jaundice, and yet when we operate we find no stones in the gall-bladder or its ducts, but we find an inducted pancreas, and a dark, thick inspissated bile; and such cases are always relieved by temporary cholecystostomy.

Opie has demonstrated that bile, when injected through the pancreatic duct into the pancreas, produces at once a very extensive acute hemorrhagic pancreatitis. Some of the animals died within twenty hours after the onset. In a few instances recovery took place. This demonstration seems to explain the cause of the hemorrhagic pancreatitis when associated with a small stone in the diverticulum of Vater. Anatomically we know that into this diverticulum both the common bile and the pancreatic ducts open. A small gallstone, smaller than the diameters of the diverticulum, may plug completely or partially the opening into the duodenum at the papilla, but on account of its smaller size it does not obstruct the orifices of the two ducts; so that the bile completely or partially dammed from the intestinal canal may pass from the common duct into the diverticulum and then through the pancreatic duct into the pancreas and produce acute hemorrhagic pancreatitis. Opie has proved conclusively that bile can produce such lesions, and without the aid of infectious agents. Clinically, he has observed the same possibility in the patient operated on by Professor Halsted. This patient, admitted in a moribund condition, died a few hours after the exploratory laparotomy. Clinically, the symptoms were intense epigastric pain, profound collapse, slight jaundice, and bile in the urine. At the autopsy there were found widespread, disseminated fat necrosis and a huge swollen pancreas with areas of hemorrhage within and without. In the diverticulum of Vater a small gallstone was found which plugged the orifice of the papilla, but did not prevent the bile from entering the diverticulum from the common bile-duct. The large pancreatic duct and some of its branches were bile-stained. This case seems to confirm Opie's experimental work. In the second case—of my own—in the same clinic a similar pathologic condition was found, except that the patient had survived the hemorrhagic stage, and when death took place there was a large peripancreatic abscess. In the literature many cases of acute hemorrhagic pancreatitis have been associated clinically with a previous history of gallstone colic, and at some of the autopsies gallstones had been found. It may be possible for the small stone to lodge in the diverticulum long enough to dam back the bile in the pancreatic duct, produce the hemorrhagic pancreatitis and then slip into the duodenum and be lost, so that at the autopsy the relation between the gallstone and the pancreatic lesion is lost sight of. Opie's experimental work and his one most positive autopsy-finding seem to prove without a question that a gallstone lodged in this position is one of the causes of hemorrhagic pancreatitis. Other causes there may be, but these are yet to be demonstrated. Surgically, this relation should be borne in mind, so that at the operation for hemorrhagic or suppurative pancreatitis the gallstone in this position should be sought for and removed, whenever the condition of the patient will allow this procedure. Flexner, in his work on "Experimental Pancreatitis," published in the "Festschrift" to Professor Welch, in 1900, has demonstrated that many substances injected into the pancreas produce pancreatitis, and states that "the element of infection plays an insignificant if not an entirely unessential part." The possibility that bile could be dammed back into the pancreas and produce hemorrhagic pancreatitis was not demonstrated or considered. Nor had Opie considered this possibility in his article of "Fat Necrosis" in the same publication.

The relation of gallstones to chronic pancreatitis is of more practical surgical interest, because the condition is cured by proper operative interference. Both Robson and Opie have demonstrated both clinically and experimentally that a stone lodged in the common duct just above the diverticulum of Vater, or completely plugging the diverticulum, produces obstruction, not only to the biliary, but to the pancreatic secretions, which in the pancreas leads to chronic interstitial pancreatitis. This lesion in the pancreas gives it a hard nodular form, often mistaken for carcinoma. Clinically, it is associated with great loss of strength and weight. The disease is rapidly cured by the removal of the stone. Every surgeon is familiar with the rapidity with which the emaciated jaundiced subjects improve after the removal of the stone. In some cases the stone is not found at the operation. It has probably passed into the intestine. Robson has demonstrated that such patients are relieved by cholecystostomy and drainages. This relieves tension, allows the absorption of the exudate, and the pancreatic duct becomes patent again. The chronic interstitial pancreatitis disappears; the general health and condition of the patient improves. This explains instances in the experience of every abdominal surgeon. Such patients have a history of recurrent gall-bladder attacks with more or less jaundice, and more or less loss of flesh and strength. At the operation no stone is found to explain the symptoms. If the pancreas is palpated it is found to be hard and nodular, almost like in carcinoma,

the bile dark and inspissated. If cholecystostomy and drainage for a few weeks is performed, the condition is entirely relieved. Robson reports cases which he thought at the operation might be carcinoma, relieved by this procedure. These observations would seem to indicate that we would better perform temporary cholecystostomy in all cases coincident with the removal of stones from the common duct.

Dr. Miles F. Porter, Fort Wayne, Ind.—I think a better conception of the essential nature of so-called gallstone colic and the essential factor at the bottom of jaundice will help us out of the trouble. Gallstone colic is not the result, it is not produced in all probability by the passage, of a stone. You will not have gallstone colic until you have your ducts or gall-bladder infected, and plugging of the common duct so as to entirely prevent the passage either of bile or pancreatic juice is one of the rarest things in connection with gallstones. The point I wish to make is this, that the pain of so-called gallstone colic has behind it infection and inflammation; that jaundice has the same thing in the vast majority of cases, and I think that the experience of most of us who have done work in this line will bear these statements out. All of us have seen cases—individuals—who have carried gallstones for a long time without symptoms until symptoms of infection arose.

Dr. C. W. Phillips, Rocky Ford, Colo.—Strictly speaking, there is no such thing as *x*-ray burn. This peculiar kind of burn or dermatitis is the chemical effect of electricity and is not due to *x*-ray penetration. We infer from what Monell says in his "Manual of Static Electricity," that the coil is more capable of producing this dermatitis than is the static machine. Now I would ask the question whether it has been the experience of anyone present who has been using the static machine to have had in his practice *x*-ray burns? In my limited acquaintance with the static machine I have not met with this misfortune, nor do I feel any fear of it. I will venture to offer the suggestion, that with the subject sufficient distance from the Crooke's tube, and with proper insulation, the so-called *x*-ray burns will occur quite infrequent, if they occur at all.

Dr. T. J. Maxwell, Keokuk, Iowa—I had occasion to operate on a lady who was taken violently ill after riding a distance in the cars. I saw her some four days after the attack. She had a tumor just above the umbilicus. I asked her how long she had had that. She said that she never had a tumor, that there was never anything the matter with her; that she always had a good appetite, regular bowels, and nothing the matter with her for years. I said: "Here is a tumor." She said she was taken suddenly ill after riding a distance in the cars and that she vomited, had pain and she felt something tear in her stomach. I operated and found that the stomach was attached to a large gall-bladder, larger than my fist, which had made a half revolution, carrying the stomach and duodenum with it, preventing all egress from the stomach and pylorus and I found in the gall-bladder 193 stones, one of them plugging up the cystic duct. I extracted them and curetted the gall-bladder, sewed it up and attached it to the peritoneum, so that it would not make another half turn, and she is now quite well.

Dr. A. C. Bernays, St. Louis—In my entire experience, now over twenty-five years, I have met with but three cases of acute cholecystitis, in which there were such symptoms as Dr. Eisendrath related. I mean by that, temperatures reaching 106 and in one case 107 F. In those cases it soon became apparent that there was a peritonitis and in all those cases I was called in by a general practitioner who recognized the extent of a peritonitis, which he did not refer, with any degree of certainty, to the gall-bladder, but that it was a hepatitis or a pancreatitis, or, in one case, the physician thought it was an appendicitis which had worked up behind the colon up toward the liver. I operated on all of these cases and succeeded in saving two. In the one case I found the gall-bladder gangrenous, looking like a gangrenous appendix, surrounded by adhesions, and I was enabled to remove the whole thing by scooping it out with my finger, leaving an enormous putrid cavity, which I treated by the open method—free drainage. The entire bladder, with the cystic duct, was gangrenous, but had been shut off by a wall of newly-formed tissue. In regard to the point made by Dr. Porter, I do not think that our attention is called to the existence of gallstones only when there is infection. It would be impossible for me to admit that, because I have operated on a great many cases of stone in the gall-bladder and stone in the common bile duct, where there was absolutely no inflammatory condition present and still the patient had jaundice and fever—the stone was in the common duct. It is true that the fever is not easily accounted for in these cases and I myself was surprised not to find some kind of infection along the bile tracts. On the other hand it is quite true that a patient may carry a gall-bladder more or less full of gallstones for years and that they will give no trouble until the patient has typhoid fever or until the patient has an ordinary pharyngitis—an angina or some other mild form of infectious disease—and then there will suddenly be pain and empyema of the gall-bladder, but I think the Doctor goes too far when he says that our attention will be called to these conditions only, or nearly always, first, by an infection. There is no doubt that the mere mechanical passages of gallstones will give rise to great pain and even to rise of temperature, and I think that the point brought out by Dr. Bloodgood is a very valuable one.

Dr. Leonard, in reply—I wish simply to emphasize the fact that there are calculi in the kidneys and ureters that will pass without operation. The detection of calculi is not always easy. The smaller calculi sometimes require a repetition of the examination. I have published my failures and also my successes in other papers. I have had one case of error through defective technic—it has been published. I missed the stone in the upper pole of the left kidney; I misread the plate. Mistakes are possible in the *x*-ray in reading the findings, as well as in other methods. In reference to the point raised in regard to one shadow hiding another: Recently a physician sent me a case for examination for calculus. The patient had lately passed a stone. He had the stone with him and asked me to put it on the plate, under his lumbar region and see if I could show it. He brought it to me in a little paper pill-box. I placed the stone in the box under the loin and both the box and stone showed distinctly in the negative through the lumbar shadow.

As to the word "opacity." Its meaning is different now since the discovery of the *x*-ray. The question is not whether one shadow is denser than another; it is whether the sum of shadows in one area is greater than the sum of the shadows in another. That is the reason why we can show the shadow of the kidney in the lumbar region. The negative diagnosis I have found to be as accurate as the positive.

We are dealing with an element in the *x*-ray about which we do not know any more to-day than when it was discovered. It is the *x*, the unknown still, and so long as we do not know what it is, it is difficult to tell the nature of all its actions. I myself do not believe that the *x*-ray itself is the agent which causes the burn. I believe that it is rather the effect of the electricity upon tissue. I myself have burns upon my hands and I seldom put them in the path of the *x*-ray. I get them from the induction effect of the current. In reference to the static machine, I have met a number of men lately who have used the static machine and they told me that they have had burns. While here in St. Paul, one of the exhibitors in the exhibition connected with the meeting told me that he had furnished one of the gentlemen who was exhibiting a static machine with a pair of rubber gloves when operating, because he could not keep the burns from his arms. I think that it is true that the static machine produces the burn as well as the coil. As Dr. Rodman says, it is in the proper use that we are to look for protection in using the *x*-ray. I have found that the introduction of a grounded screen of aluminum attached by some metallic connection with the ground has been a great protection. I have had a number of burns. I had two serious burns, but those occurred before I knew it was possible to produce them. It is as yet impossible to absolutely

protect from burns, no matter how careful and expert the operator may be. The danger is, however, very slight. At the present time I am using a 4-inch coil for my work—a coil which I have had constructed on special lines. I find it sufficient. The spark has volume and sufficient length to overcome the resistance of the tube. It is the volume in the secondary discharge that is essential to good *x*-ray work.

The point I would like to emphasize particularly in reference to my paper is that I have here a method which determines accurately the position and presence of calculi and the size of those calculi, making it possible for us to leave to Nature in selected cases what she often accomplishes. The fact that there are more ureteral calculi than we had supposed shows Nature's tolerance of them. The same is as true here as in the papers brought out on the biliary calculi. There we find calculi quiescent until some infection lights up and aggravates the condition present and shows the presence of the calculi.

DR. D. N. EISENDRATH, in reply—I agree with Dr. Porter, and in answer to Dr. Means, in regard to the fact that infection is, in the great majority of cases, the first symptom, or is the cause of the first symptoms of the presence of gallstones; a patient may have gallstones, as shown by Kehr and a number of investigators; they may go through an entire lifetime without having become aware of their presence, but when infection begins and the patient has a cholecystitis or cholangitis that causes, as Riedel has shown, an inflammation around the foreign bodies; there is contraction of the gall-bladder muscles and common-duct walls and, as a consequence, the patient has gallstone colic, but the stones are seldom expelled. As to the question icterus, we can distinguish between the two varieties of jaundice. There is the inflammatory jaundice which is of slight degree and which is almost invariably present during the course of gallstone colic and is known as the inflammatory icterus, in which there is a small amount of absorption of bile by the gall-bladder walls; and so-called obstructive icterus, in which the obstruction is caused by a stone, usually in the common duct.

I desire to relate some interesting experiments made by the Japanese investigator Miyake. He found that when he injected virulent colon bacilli in the gall-bladder of animals he produced no change, except a slight catarrhal change in the gall-bladder. If partial obstruction of the common or cystic duct is produced, particularly the latter, by passing across it a portion of the omentum to obstruct it, or ligating it incompletely in other words, and then, at the same time, one injects micro-organisms into the bladder, we have the two conditions now recognized to be essential in the gall-bladder infection plus obstruction to produce stones. These are the clinical causes. In two dogs, after the lapse of nine months, and twelve months, in another case, he produced gallstones which, upon analysis, had the typical composition of such calculi; that is, the experiments have proved what we have known since 1891, when Nauyn first proposed the stone-forming theory, that stones are not due to acid precipitation of bile, but that the colon and typhoidal bacillus and the resultant catarrh is the most frequent cause.

In regard to primary suture in gallstones, I think it is the general opinon of men who have had experience—from 400 to 600 cases each—as Mayo, Robson, Kehr and Riedal, that we ought to abandon it as a routine procedure. It is dangerous to close the gall-bladder in every case. It is better to do one of two things: either obliterate the gall-bladder entirely by cholecystectomy, or follow the procedure of the majority of surgeons and drain the gall-bladder, in that way getting rid of the infection. Peterson has shown in cholecystitis purulenta, that the examination of the bile escaping from the fistula shows at the end of ten days that the bile is sterile, so that by such perfect drainage we can obtain good results. In answer to Dr. Bernays, I would say that in our case there was positively no peritonitis. The condition of the liver and the slight obstruction caused by the stone which was lying in the diverticulum of the cystic duct, the lack of escape of fluid, and chiefly the condition of the liver, was the cause of death.

DR. J. B. BULLITT, in reply—I am familiar with some cases of empyema of the gall-bladder, which, through rupture, have produced abscesses of the abdominal wall. I purposely omitted this class of cases in my paper, for the discussion of all cases would lead us too far. I believe that the experience of the last few years has demonstrated that stone in the kidneys and ureters is of much more common occurrence than had before been believed. I believe further that the chapter of kidney surgery has expanded most wonderfully in this time and is destined to expand more rapidly and to be reckoned in the next decade in the brilliancy of its results with the surgery of the gall-ducts and appendicitis. I find that there has not been so much work done which will reflect so much credit on this particular chapter of surgery, and which will be of such benefit, as the light which has been thrown on this matter through the means of the *x*-rays, and of all those workers who have added their knowledge to this chapter in surgery, no one is entitled to as much credit as Dr. Leonard. I have, for several years, worked in the kindergarten of the *x*-ray and I think the difficulties to be encountered by one who undertakes examinations by these means are very great. Of all the operators in this country there have been comparatively few up to the present time who have developed a technic which is sufficient for making a positive and negative diagnosis. I believe the time is fast coming when the accumulating experience of men will prove that we shall have this safely at our command.

Dr. Bevan has laid stress on the fact that as far as the determination of kidney stone is concerned, the *x*-ray is more important than the operative exploration of the kidney. He has reported one, perhaps two, cases in which kidney stone had been expected, in which an exploratory operation had been made. The kidney had been incised and the pelvis explored. The kidney had been needled in all directions and no stone had been found. The symptoms persisting, the patient was afterward submitted to the *x*-ray and a very clear and distinct shadow of a stone was found. I have had a similar experience, although not with a kidney in situ, but one that had been removed on account of extensive destruction, from a large kidney stone in the pelvis of the kidney. Desiring to experiment with the shadows, I placed the kidney on a photographic plate and made an exposure and was very much surprised to find on developing that the shadow of a second stone was present on the plate. I exhibited this stone before the Surgical Society in Louisville and opened the kidney over the point indicated by the shadow and found there a second stone which had not been found at the time of the removal of the kidney. If this method of Dr. Leonard were followed, mistakes could not occur. If a patient is operated on after a stone has been determined in this way, it will not be possible to remove one stone and leave another in place.

Concerning the term "*x*-ray burn," we all know what we are talking about. All of the various types of apparatus are capable of producing burns. I have used the static machine, the Tesla coil and the induction coil. I have never produced a burn in anyone but myself and that was produced by means of the static machine.

Clinical Report.

ANKYLOSTOMIASIS—REPORT OF A CASE.

R. LEE HALL, M.D.
BALTIMORE, MD.

This being one of the few cases of ankylostomiasis to be reported in this country, I present it to the profession.

The patient, J. O'R., aged 38, an Englishman, was employed as a sailor on a vessel plying between Liverpool and cities in the United States. On his last trip the vessel touched a port in Mexico (Vera Cruz) a few days before entering any ports of the United States. Whether or not the man visited other ports or was subjected to circumstances conducive to the contraction of this disease could not be ascertained. He arrived in Baltimore about the last of September, feeling extremely weak and debilitated and suffering from some obstinate

intestinal trouble. In consequence of this general condition he abandoned his return trip to Liverpool, entered a sailors' boarding house, and after remaining there for three or four days was admitted (Oct. 2, 1901) to Bayview Hospital. The history gained elicited the fact that he had been suffering from general malaise and debility for about six months prior to his arrival in this city. He had commenced to lose appetite and energy the latter part of the spring, and this condition gradually developed into a general disability.

About a month ago his symptoms became more grave, a troublesome bowel disorder ensued, the discharges at times being tinged with blood. However, he was not compelled to abandon work until he reached this city in September. At the time of his admission to the hospital his condition was at once considered grave on account of the emaciation and anemia. A dry cough was noticed. His temperature on admission was 100 F. and varied between this point and 98 throughout the course of the disease. The evening temperature was about a degree higher than that of the morning, thus simulating a tuberculous condition.

The physical examination elicited the following: The face was emaciated and pale; the eyes were bright, pupils somewhat dilated, reacting normally to stimuli; conjunctivæ pale; tongue was coated white and the breath was offensive. Clavicles and ribs were prominent; skin free from eruptions, and very pale. Palpation and percussion elicited nothing abnormal. On auscultation a few sonorous, sibilant and mucous râles were heard distributed pretty generally over the chest. Respirations were 24 per minute. Dyspnea was quite marked at times. Heart sounds were weak, and pulse 100 per minute. No increased dulness was evident on percussion. A hemic murmur was occasionally heard over the apical region. There was no increased hepatic or splenic dulness. Pain points were evident over various portions of the abdomen on palpation. No lumps were found in the abdomen. The reflexes were normal. The whole body showed marked anemia and emaciation. There were no signs of edema. The urine was pale in color; specific gravity 1016, contained no albumin or sugar. The sputum was frothy, but contained no evidence of tubercle bacilli.

These symptoms suggested either amebic dysentery or tubercular enteritis. A microscopic examination of the feces was made, but nothing was found to confirm our suspected diagnosis. There was found, however, in addition to blood, certain strange-looking ovoid granular bodies, much larger than red blood corpuscles, the true character and source of which was not recognized, and in fact very little importance was attached to their presence.

The postmortem examination revealed, as will be noted below, that these bodies were the eggs of the parasite ankylostomum duodenale, the true cause of the disease. An examination of the blood was made two days after the patient's admission to the hospital, with the following results: red corpuscles, 2,500,000 per cubic millimeter; white corpuscles, 24,000; stained specimens showed a great increase in the polynuclear leucocytes and eosinophiles, the relation of the eosinophiles being 26 per cent. A small percentage of nucleated reds were found present, of the microblastic and normoblastic types. Poikilocytosis was absent. The general size of the red corpuscles was about normal; however, a few microcytes and macrocytes were present, the former predominating. A few days later the second examination showed a slight increased leucocytosis.

The pains in the abdomen were of a dull, nagging character, with an occasional paroxysm of great severity. About two days prior to death a final blood examination was made, with the following results: red corpuscles, 800,000 per cubic millimeter; white corpuscles, 29,600; hemoglobin, 11 per cent. Stained specimens at this time showed an increase in the nucleated reds. A slight poikilocytosis was now present, with some increase of microcytes. The most striking change was the increase of the polynuclear leucocytes and a decrease in the eosinophiles, the eosinophiles now only aggregating 3 per cent. A few lymphocytes and large mononuclear leucocytes were to be seen.

From this time on the patient rapidly failed. Respiration became more labored and gradually decreased in frequency, and he died on the evening of Oct. 19, 1901. An autopsy was made the next day by Dr. Yates, of the Johns Hopkins University. A brief summary of the findings being as follows:

Body was marble white in color, slight rigor mortis present 18 hours after death. Peritoneal cavity contained an excess of clear fluid, but the surfaces were smooth and glistening. The pleural cavities contained some turbid-looking fluid; no apparent congestion; some old adhesions to posterior chest wall. Lungs were edematous on the dependent portion; much black pigmentation of the tissue and old tubercular foci were present. The bronchi contained much frothy fluid, with no evident congestion of the mucous membrane.

The pericardial cavity contained a small amount of clear fluid. The blood clot in the heart was pale and tenacious; cut section of the muscle gave evidences of fatty degeneration. The valves were apparently normal. There were also evidences of fatty degeneration in the liver and kidneys. Extreme paleness of all viscera was present.

On opening the intestines about five or six inches from the beginning of the duodenum, a hemorrhagic-looking substance was found, small in amount. On close inspection of this substance there was revealed numerous small whitish worm-like bodies averaging from 7 to 16 mm. in length. As we opened the tract downwards the same condition existed until about 6 feet from the origin of the jejunum a more striking condition was encountered. These little worm-like bodies were now found to exist in great numbers. They were noticed to be in a living condition and many attached to the mucous membrane. They were thought to be the ankylostomum duodenale parasite which, after microscopic examination, proved to be correct. These parasites were abundant down to the colon and a few extended as far as the rectum.

The stomach contained no parasites. The entire intestinal canal was bathed in a tenacious mucus. The mucous membrane was pale, with here and there slight hemorrhagic areas. Along the free margin of the valvulæ conniventes greater hyperemia was noticed.

The microscopic examination of the bowel contents revealed large numbers of the previously mentioned ovoidal bodies. They were now recognized to be the eggs of the parasite, and the supposed granular condition was known to be various stages of segmentation. Had we been fortunate enough to have recognized the eggs found in the antemortem microscopic fecal examination a correct diagnosis would have been reached and proper treatment employed, resulting possibly in saving the man's life. This illustrates the necessity of making a thorough microscopic fecal examination in all intestinal disorders, when associated with marked anemia.

Quantity or Quality?—It is plain that the medical college which adopts as its motto, *quality rather than quantity*, must have either a large amount of virtue or a small amount of endowment, or some of both. The lower the standard of admission and the quality of teaching, the poorer it is, either in virtue or endowment. There is at present a rage for large classes in our literary colleges that is an ominous sign of education debasement. The college president who succeeds in swelling the numbers in the classes is held to be the most "successful." That Williams College thinks otherwise and prefers by elevation of her standards to lessen the mere number of her matriculants is a hopeful sign. A number of our medical colleges are like-minded, and in view of the fact of an already overcrowded profession, with a future lessened function, it is the clear duty of every physician to encourage those schools whose standards are in advance of others. Every established physician is asked by young men whether he should study medicine or not, and at which college he should matriculate. So long as the poor commercial college is advised so long will our present educational disgrace persist, and so long does the fault lie at our doors. We have the cure of our special evil in our own hands. We must starve the low-standard commercial medical college to death or to decency.—*American Medicine.*

GUARNIERI'S VACCINE BODIES.

In 1892 Guarnieri announced that by inoculating vaccine lymph into the cornea of rabbits certain cell inclusions—"cytoryctes"—form, which he and others after him are inclined to regard as the causative agent of vaccinia. These experiments have been repeated by others and the results obtained have been interpreted variously, some regarding the bodies as parasites, others as the product of cellular degeneration. An exceedingly thorough and elaborate study was made by Hückel,[1] who reached the conclusion that the intracellular bodies in question were the products of a specific degeneration of the cytoplasm induced by the vaccine virus and by the vaccine virus only.

In the meantime the whole subject has been worked over again in what seems to be a most painstaking and critical manner by Wasielewsky[2] in C. Fraenkel's Institute in Halle, and from this article, which is the summary of work extending over eight years, the following conclusions seem to merit general notice: The so-called vaccine bodies appear regularly in the epithelial cells of the rabbit's cornea when active lymph is introduced into a small canal or pocket in the cornea. These bodies correspond to the bodies found in the skin in variola and vaccinia, bodies that do not occur in the healthy skin or in skin the seat of other lesions than those mentioned. From a careful review of the work of others, as well as from their own results, both Hückel and Wasielewsky are firmly convinced that these bodies can not be made to appear in the corneal cells by any other procedure. The vaccine bodies are not leucocytes or the products of leucocytes, and they do not spring from the nuclei of the epithelial cells of the cornea. There are many considerations that speak against their development as the result of specific toxic action on the protoplasm of the cells—Hückel's theory. Such specific toxic action affecting single parts of cells does not seem to be known outside of this possible case, and such rapid vacuolation and granular disintegration as are seen in the vaccine bodies do not occur in degenerative products. The vaccine bodies occur in dividing cells—an observation somewhat difficult to reconcile with the view that they are of toxic, degenerative character. The filtrate of vaccine lymph is inactive and it does not produce vaccine bodies in the cornea. On the other hand, the number, size, structure and distribution of vaccine bodies correspond well with Guarnieri's view that they are cellular parasites.

Wasielewsky shows that active vaccine may be obtained after successive inoculations from cornea to cornea through no less than 46 generations, a circumstance that points strongly to the proliferation of the vaccine virus at the points of inoculations. Careful microscopic and bacteriologic examination failed to show ordinary micro-organisms in the corneal inoculations, whereas the vaccine bodies occurred constantly from first generation to last. Hence Wasielewsky regards Guarnieri's view that the vaccine bodies themselves are the active agents of vaccine as very probably correct. Inasmuch as the causative agent of vaccinia is held back by filters there is no good reason to regard it as so remarkably minute that it can not be seen with the optical means at our command. On the whole Wasielewsky makes out a strong chain of presumptive evidence in favor of the etiologic rôle of the vaccine bodies. The fact that active vaccine, as shown by experiments both on calves and on children, was secured after 46 inoculations from cornea to cornea at intervals of a few days, vaccine bodies appearing in plentiful numbers in every cornea, certainly indicates the closest possible relationship between vaccine virus and vaccine bodies. At the same time Wasielewsky does not insist that his interpretation is definitive and unchangeable. Granting the parasitic character of vaccine bodies, too little is as yet known about them to warrant discussion as to their exact nature, whether protozoic or vegetable. Their possible relations to Funck's sporidium vaccinale[3] must be left in abeyance for the same reason.

ANKYLOSTOMIASIS.

The report in this issue by Dr. Hall of a case of ankylostomiasis in a sailor, dying from this disease in Baltimore, shows the importance of careful examination of the feces in obscure cases of anemia associated with intestinal disturbances. Ankylostomiasis, or uncinariosis, is a comparatively unknown disease in the United States. In some of the new possessions, however, it is probably quite as frequent as in other countries, such as Egypt. According to Lieutenant B. K. Ashford[1] ankylostomiasis is the most general and most harmful disease—a veritable curse—in Porto Rico. Allyn and Beard[2], reporting a case in an Italian in Philadelphia, review some of the cases observed in this country, and they express the belief that it is more frequent than the few scattered reports seem to indicate[3]. The diagnosis is established by finding the ankylostoma eggs in the feces. The eggs are described by Manson[4] as beautifully clear and transparent, 55 to 65 by 32 to 43 mikrons in

size, oval, with delicate transparent shells, through which two or four light gray yolk segments can be seen distinctly. The ova are to be sought for soon after the feces are passed.

As indicated by the variety of names bestowed upon the disease (brickmaker's anemia, miner's cachexia, tunnel anemia) it occurs especially among laborers that come in close contact with dirt and soil. The disease is of extraordinary frequency in Egypt (Egyptian chlorosis), Ceylon, India and elsewhere, especially in tropical and subtropical countries. A very fatal epidemic among the laborers in the St. Gothard tunnel in 1880 called the direct attention of European observers to the disease and to the significance of the minute, blood-sucking parasite that causes it. Ankylostomum duodenale, or uncinaria duodenalis discovered by Dubini in 1838, inhabits the jejunum and adjacent parts of the intestine; it attaches itself to the mucous membrane and imbibes blood freely, producing a severe anemia by removing blood, the plasma alone being utilized by the worm; it is probable that it also produces a toxic effect. Dyspeptic symptoms and intestinal disturbances are also caused. The female worms produce a prodigious number of eggs, which hatch outside the body if kept warm in feces mixed with soil. Manson states that Grassi and Parona have estimated that 150 to 180 eggs per cubic centigram of feces indicate an infection of about 1000 worms, male and female; this gives an idea of the intensity of the infection.

The authors are not in accord as to the mode of infection. Many assume that the parasite enters the intestine "by chance," either in muddy drinking water or by way of mud and dirt adhering to the hands, food or eating utensils, while Looss[5] advances the theory that the larvæ enter through the skin. Placing a drop of suspension of larvæ upon the skin of an extremity an hour before amputation, Looss saw that the larvæ penetrated into the hair follicles. Looss claims that he became infected in this way. As larval suspensions dry on the skin an area of redness and burning results. Looss' theory makes infection of those who work in soil very easy. The reasons that would determine the localization of the mature worms in the jejunum seem very obscure, but not any more so than those that determine the wanderings of trichinella spiralis into the skeletal muscles. The prophylaxis of ankylostomiasis rests upon the prevention of mixing of fresh infected feces with earth. In the curative treatment the principal agents, according to Manson, are thymol and male fern. Thymol is now used more commonly than male fern, the quantity being three or four 10 to 30 grain doses on an empty stomach at intervals of an hour, preceded by a thorough emptying of the bowels, and followed by rest in bed and avoidance of alcoholics. "An equally efficient but safer drug is a desideratum."

THE MEDICAL POLITICIAN AND THE MEDICAL STATESMAN.

In general public affairs the distinction between the politician—in the *fin-de-siècle* rather opprobrious meaning of the word—and the statesman, is not a difficult one to apprehend. Popular usage has determined the signification of "politician" to be "one who interests himself in public affairs for personal gain," while "statesman" still means "one who devotes his time and energies to the public weal," asking no reward but that satisfaction which comes from a sense of duty well done. In medical polity, which is coming to be an important department of medicine, the term "medical politician" has been for many years freely used in the opprobrious sense. That it has in large part been thus justly employed it is fruitless to deny. The facts are well known to all. The term "medical statesman" has up to this time not been found necessary. The need for it, however, is at hand, for a race of medical statesmen is already among us. They have been few, but are steadily increasing in number and influence. In the various states to-day pure-hearted physicians are cheerfully sacrificing time and means in the altruistic task of properly organizing the medical profession and of leading it towards its highest ideals of public and professional usefulness. These men ask no reward except the satisfaction of having accomplished good work. They are content with the respect of their fellows. Viewed from the standpoint of economics they are constructive statesmen, and the more honorable descriptive term should not be withheld. They are not "politicians" in the up-to-date American sense of the term. They should be honored, as well as very properly now are the pioneers in scientific medical research, in order that others whose tastes run in this direction may be encouraged to follow the same paths. Medicine in America to-day stands in need of just such a body of physicians.

No doubt, as was the rule in the past, designing ones in hope of personal enrichment in money or reputation, will attempt to pose as leaders in this branch of medical polity, but physicians can in a short time readily discriminate between him who works for the general good and him who seeks only self-advancement. The marks are not difficult to read, especially in the eyes of an educated profession. Everywhere physicians must see to it that the true statesmen of the profession are put to the front in those places in which they are so greatly needed. For instance, the secretaries of the state medical societies and the delegates to the House of Delegates of the American Medical Association should be carefully chosen from this class. The presidents of the state medical societies and many other officers in all descriptions of medical societies may appropriately be men who have attained eminence in practice or in scientific research, but the secretaries and delegates should be honest men of medical affairs.

Let us seek for and encourage the real statesmen among us. Let us put them where their talents will be

of the greatest service to medicine, and then let us support them heartily and loyally. In return for the loss of practice necessarily sustained by those who honestly execute the duties of such offices as demand continuous effort and time-consuming attention, the members of medical societies—who should be all eligible physicians—should freely put their hands in their pockets. Valuable time and fruitful endeavor must be compensated at least to the extent of insuring the livelihood of those who conscientiously give their time for the general good. Other callings with vastly less high ideals have long followed this policy with great benefit to themselves. Why should the physician refuse to do the same? Let us encourage a race of fairly-paid medical statesmen, and then medicine will shortly occupy a place in public esteem and sociologic influence that is otherwise absolutely unattainable. In South and Central America and on the continent of Europe, physicians frequently play the highest parts in public affairs, greatly to the benefit of the nation and to the standing of the profession of medicine. The same thing can be done in the United States if physicians are willing to follow the suggestions herein outlined. We must find a proper place for the term "Medical Statesman."

PROGRESS IN GLANDULAR SURGERY.

Recent advances in abdominal surgery have made certain supposedly hopeless medical conditions amenable to surgical treatment with very satisfactory results. Morrison's operation for the establishment of a collateral circulation to relieve the congested portal circulation, and so prevent the annoying ascites which is so marked a feature of hepatic cirrhosis, has in many cases afforded so much benefit to the patient as to constitute practically a symptomatic cure for some years. Jonnesco's suggestion of the removal of the enlarged spleen in cases of malarial cachexia has proved of great value in preventing the hitherto inevitable progress of the disease from bad to worse. Without serious risk in cases that are not too advanced patients are given a new lease of life. The indications and contra-indications for both these important operations are now in course of definition at the hands of surgeons in many countries and the prognosis and eventual limitation of applicability of the procedures to individual cases will soon be established.

When with serious degenerative conditions in these large abdominal glands, the liver and spleen became the favorable objects of surgical intervention, it was almost to be expected that kidney disease would also prove amenable to enterprising yet conservative surgery. There are two recent reports in this matter that are most encouraging. While in this country last year Mr. Reginald Harrison, the distinguished English genito-urinary specialist, mentioned in his lectures his favorable experience with operative interference in certain severe cases of acute nephritis. The anuria that sometimes develops during acute kidney disease, Mr. Harrison believes to be due to congestion of the organ. The pressure within the kidney capsule becomes so great that secretory activity is eventually inhibited. This condition which Mr. Harrison epitomizes as glaucoma of the kidney, can be relieved by slitting the renal capsule. The urinary secretion is at once re-established and unless the pressure within the kidney has been allowed to continue for so long that parenchymatous degeneration has set in, recovery from the hitherto usually fatal anuria is complete.

Another phase of surgical intervention in kidney disease, this time chronic, came up at the recent meeting of the New York State Medical Association. Professor Edebohls, of New York City, in discussing the subject of floating kidney, said that in his experience three cases of chronic nephritis had been relieved after the formation of adhesions for the anchorage of a prolapsing kidney. The relief afforded in one case three years after operation, amounts to a symptomatic cure. Not only has the albumin disappeared from the urine but the tendency to edema has been overcome and the general health has distinctly improved. After several years with almost constant loss of weight the patient has now put on flesh. The other cases are as satisfactory in their results, though not under observation for so long a time. Dr. Edebohls now proposes, in cases of chronic nephritis, to attempt their surgical relief by operation for the production of extensive kidney adhesions.

Dr. Edebohls' theory of the cause of the benefit that accrued to these patients is that the increased blood supply obtained by the kidney from the adhesions prevents further degeneration and encourages the formation of new portions of kidney substance. It seems to have been demonstrated experimentally by German observers that new islets of renal parenchyma may be formed even comparatively late in life. As we begin the new century we are probably in the presence of an unexpected but beneficent invasion of surgery into what has been hitherto deemed the exclusive domain of medicine. Further surgical intervention for the relief of glandular disease may be confidently looked for. The field is large and surgical success will be welcomed by the medical man for whom these cases have, as a rule, been obstinate to treatment and despairingly hopeless.

TRADES-UNIONISM IN MEDICINE.

Recently our news columns have contained reports of the forming of medico-business organizations in various parts of the country, their objects being to protect their members against dead-beatism—to coin a word. Some of them have adopted a rule of fining any member who professionally attends those who are blacklisted. It seems that it might be possible to devise a better method than this for self-protection. It has the unpleasant flavor of some of the tyrannous methods of trades-unionism, which as members of an honorable and learned profession we will do well not to adopt. All our humanitarian

traditions are against such a course and upon the proper maintenance of these depends much of our self-respect as well as the respect in which we are held by the public. No medical practitioner can profitably sacrifice his time and services for ingrates and dead-beats, and this alone ought to be sufficient to prevent any systematic breaking of any agreement by members of the organization, bu a fine for doing what might possibly be a necessary act of common humanity is not in accord with medical or any other ethics. These organizations would do well to repeal the regulation, which is more likely than not, if left unrescinded, to damage their future usefulness and possibly imperil their existence.

DESTROY CHINATOWN.

The Annual Report of the San Francisco Board of Health contains the following paragraph:[1] "Chinatown, as it is at present, can not be rendered sanitary except by total obliteration. It should be depopulated, its buildings leveled by fire and its tunnels and cellars laid bare. Its occupants should be colonized on some distant portion of the peninsula, where every building should be constructed under strict municipal regulation, and where every violation of the sanitary laws could be at once detected. The day has passed when a progressive city like San Francisco should feel compelled to tolerate in its midst a foreign community, perpetuated in filth, for the curiosity of tourists, the cupidity of lawyers and the adoration of artists." The Board of Health of San Francisco has made an honorable record in its fight against the plague and the unprincipled commercial interests backed by the state government. That it has had to make this fight is due to the existence of Chinatown which perpetuates a state of heathen barbarism in the central business section of an American city. It is a wonder that it has been tolerated so long; as it exists it is a pestilent nuisance endangering the health not only of the city but of the State of California and the whole United States. Its abolition ought not to be expensive; its proprietors obtain their present income by maintaining it as a nuisance, and with it redeemed and put to decent business uses they ought to be well repaid for any loss by an enhanced value of their real estate. So long as they permit it to be continued in its present condition it would be only decent justice to mulct them by heavy fines for keeping up a disease-breeding nuisance.

THE SPREAD OF EPIDEMIC CEREBROSPINAL MENINGITIS.

At the nineteenth Congress for Internal Medicine in Berlin, in April this year, Jäger called the attention to certain interesting conditions in regard to the spread of epidemic cerebrospinal meningitis. This disease has not figured to any extent in the ordinary statistical tables except when more marked epidemics appeared. Since it has become more or less common and in some places even a fixed custom to endeavor to establish an etiologic diagnosis of sporadic meningitis by means of the bacteriologic examination of the exudate obtained by lumbar puncture, it has been found that probably the majority of the cases of sporadic meningitis are caused by the meningococcus, that is, belong to the epidemic form. An exact statistical study is not possible as yet, but from the figures at hand Jäger points out the remarkable fact that epidemic cerebrospinal meningitis appears to be "exorbitantly widespread" in certain American localities, especially in New York, Boston and other cities. He speaks of the United States as the seat of endemic foci of the disease, whence it is carried to European seaports, which in turn become new centers of dissemination. He would explain the recent epidemics in Copenhagen on this score. Considerable numbers of cases have also occurred in Hamburg and Kiel. The evidence on which Jäger makes this deduction does not seem to be free from other equally reasonable interpretations. Granting that the germs may be transported across the Atlantic, it would seem rather singular if other seaports in Europe did not also become infected, if Jäger's surmises were true. He makes no reference to English ports, for instance. Certainly a more comprehensive investigation is needed before any such deductions as he draws may be warranted. As the matter now stands it would seem to be just as reasonable, if not more so, to trace the invasion of New York and Boston by meningitis to the importation of the infection from European ports.

1. Quoted in the San Francisco Bulletin of November 15.

POLITICS AND HEALTH OFFICERS.

It has been a pleasure during recent years to observe the excellent work that is being done in the way of preventive medicine by the health departments of several of our large cities, under the management of efficient and qualified health officers. The work done is worthy of the commendation and encouragement of all. That it demands special knowledge that can not be learned in a day is recognized by everyone who is competent to form an opinion, and is evident even to the laity when they take notice of the differences that exist between a competent and an incompetent administration. It seems to be a needed step further that politicians should come to recognize this fact. Just why political partisanship should be a qualification for such office would be a hard matter for them to explain, but they act too often entirely upon this presumption. Ordinary business common sense would condemn the spoils method here, but there is a moral argument that is still stronger against it. Shall the public health be endangered by inexperience, by the lack of interest and zeal that such a system entails? If officials were held duly responsible for the consequences of their acts, there would be a fearful score against those who by unfit appointments and political changes endanger the public health. These thoughts are suggested by the fact that there is in the city of Buffalo at the present time an active interest on the part of the medical profession in a proposed change in the health office there. Dr. Ernest Wende, who has held the position of health commissioner for ten years, has made an admirable record, but is likely to be removed on political grounds. The physicians, however, are strongly and righteously exercised about it and are doing what they can to have Wende retained. There

is no criticism of him personally, nor of his work; the only reason apparent is that he does not belong to the political party coming into power. Its leaders and the mayor-elect, who has the appointing power, will do well for themselves and their party if they disregard the unwholesome precedents of the party spoils system and keep a competent and efficient official instead of putting what may with absolute truth be called the vital interests of the city into untried hands. The time has pretty nearly arrived when politicians who sacrifice these for the sake of personal or party reasons will be considered public enemies and violators of a sacred public trust. There is no better opportunity than this for the mayor of Buffalo to demonstrate his fitness for his position and due sense of his official responsibility.

THE CANADIAN MEDICAL PROFESSION.

A Canadian journal[1] takes up the proposition to establish a branch of the British Medical Association in Toronto and does not look upon it altogether with a favorable eye. It complains of the small part Canadian physicians take in the medical progress of the world and sees but little stimulus to effort in the small and ill-supported provincial medical societies. It doubts, however, whether making themselves an appendage to the larger bodies of the mother country will be a remedy. It says that Canadians lack confidence in themselves; they are always looking to England, over-rating English medical qualifications as compared with their own, which really represent as high or even higher attainments, and generally accepting the subordinate position that seems to be considered proper. They are, our contemporary suggests, too content to "bask in the reflected light of British medical achievements" and not independent and enterprising enough to make a name for themselves. We would have hesitated to offer these criticisms ourselves for fear of hurting their feelings, and in repeating them here we do not wish to unqualifiedly endorse them. There are Canadians doing good work in McGill and elsewhere and we hope there will be still more. Some of the leading Canadian physicians have taken an active part in special associations on this side of the line, where they seem to find adequate stimulus and professional sympathy. There is much truth, nevertheless, in the statements made by our Canadian exchange that so long as the Canadian profession is willing to keep up a merely colonial spirit and play second fiddle to Great Britain in professional matters it will suffer not only in its proper self-appreciation but also in the appreciation of others. Its best scientific spirit and work can not be evolved so long as such a condition exists. Britain is too distant and too insular in many ways to have the best influence on the medical profession of half a continent, even admitting that two-thirds of that half is not inhabited. The American profession is closer in medical thought to the Canadian physician than is that of Great Britain, and it will be a pity if our brethren over the line persist in ignoring this fact. We may say there are no boundaries in science, but there is a certain affinity and influence in contiguity and like environment even in scientific matters, all the more when there are no racial or linguistic barriers. The suggestion that Canadian medical men intermingle more with their American professional confrères and look less humbly up to English medicine is one that perhaps they will do well to consider. It is in no way disparaging to British medicine—which we in this country duly respect and appreciate—to say that it can not in the nature of things influence so advantageously the profession of Canada as can that of the United States. Whether the Canadians realize this or not is less a matter of importance to us than to them. The best of their leading men do realize it and give evidence of it in the professional associations.

Medical News.

CALIFORNIA.

French Hospital.—The contracts for building the new French Hospital, Los Angeles, have been awarded. The building will cost about $10,000.

Emergency Hospital.—Ground was broken, November 4, for the new Emergency Hospital, Los Angeles, which is to be erected at a cost of $50,000.

Personal.—Dr. A. W. Hitt, formerly of Chicago, has located in Geyserville.——Dr. Theodore F. Johnson, National City, has been appointed coroner of San Diego County, vice Dr. Horace P. Woodward, Escondido, deceased.——Dr. James W. Clark, Santa Rosa, sustained a fracture of the scapula and other injuries by being thrown from his buggy, November 17.

St. Elmo's Hospital Closed.—By order of Dr. Frederick W. Hatch, State Superintendent of Hospitals, the license of the St. Elmo Hospital and Sanatorium, San Francisco, has been suspended, on the ground that too much division of authority between the medical and business heads has existed and does exist, and on the further ground that proper and adequate care and treatment of insane persons is not possible under the present conditions.

GEORGIA.

Cornerstone Laid.—On November 1, with appropriate ceremonies, the cornerstone of the new building of the State Sanatorium, at Milledgeville, was laid.

Dr. A. C. Colson, Peyton, has located in Screven.——Dr. William D. Hoyt has decided to remain in Rome and has resumed practice.——Dr. Fred G. Barfield has opened an office in Savannah.

IDAHO.

New Doctors.—Out of eleven recent applicants for license to practice medicine, seven passed and were granted certificates.

Proposed Lewiston Hospital.—A favorable report has been made on the proposed establishment of a hospital at Lewiston, to be conducted by Catholic sisters, and it is expected that active work will soon be commenced on the building.

Unlicensed Practitioner Jailed.—M. A. Blatchly, who has been practicing in the vicinity of Idaho Falls, has been tried at Blackfoot for practicing medicine without a license, and sentenced to pay a find of $300 and to be confined in the county jail for six months.

ILLINOIS.

Personal.—Dr. James F. Dick, Mount Pleasant, has moved to Wolf Lake.——Dr. Robert W. Markley, Nunda, has located in Blackstone.——Dr. Henry O. Smith, Sycamore, has opened an office in De Kalb.

New Hospital.—J. Brynteson and P. H. Anderson, Rockford, have each donated $25,000, to be used in the erection of a hospital for the Mission Church, subject to the beginning of building operations before March 20 next.

Communicable Diseases.—Diphtheria is causing alarm at Evanston. Sixty cases have been reported in the last two months.——Typhoid fever is epidemic in Kankakee, where 75 cases are reported, and in the country around Ottawa.——Scarlet fever has appeared in Atlanta.——Smallpox is reported from Roseville, Roodhouse, Lukensville, and from two towns in Logan County.

Chicago.

Mercy Hospital Report.—During the last year $104,395.15 was received; and the hospital now has an indebtedness of $134,609.53. An amphitheater, buildings for nurses, and a laundry were erected during the year.

Personal.—Dr. Guy G. Dowdall, has located in Clinton, Ill. ——Dr. Edmund R. Moras, who was seriously injured in a street-car accident in 1896, which resulted in the amputation of his arm below the elbow, has been awarded $36.000 damages.

Decrease in Typhoid Mortality.—There is a marked decrease of typhoid mortality noted for the week, but the character of the water supply gives no assurance of a continuance of the present remarkable freedom from the impure water diseases.

Dunning Institutions' Investigation.—Drs. Frank Billings and Hugh T. Patrick are the medical members of the committee appointed by the president of the County Board to investigate the county institutions at Dunning. The committee has already commenced its work.

The general health of the city, as indicated by the mortality rate of 12.97 per 1000 per annum, remains good, although there is a continuous increase of the pneumonia germs found in the laboratory examinations. Influenza continues to spread, but is, fortunately, of a mild type, only two deaths from this cause being reported last week.

INDIANA.

Small Compensation.—Dr. James N. McCoy, Vincennes, who treated smallpox cases for the city for twenty days, sued the city for $650 and received judgment for $239.40, has compromised the matter for $100.

Dr. Adolf Wermuth, Fort Wayne, assistant professor of pathology at the Fort Wayne College of Medicine, has been forced to resign on account of failing health, and Dr. James B. McEvoy has taken up his work.

Smallpox is raging in Spencer County; Lincoln City and Gentryville are quarantined; Newtonville has 15 cases, and cases are also reported from Rockport and Little Pigeon.—— Three new cases have been discovered at Lafayette.

IOWA.

Smallpox has re-appeared in Council Bluffs, where two cases have been reported. The epidemic last winter has resulted in claims against the county of nearly $7000.

Physician Wins Suit.—Dr. William D. Middleton, Davenport, who sued for $170 fees for assisting at an operation, was awarded $150 by the jury. The defense was that the operation was not a success.

Personal.—Dr. Franklin W. Sells, Murray, has been appointed examining surgeon of the Keokuk & Western Railway, and will spend a portion of his time in Osceola.——Dr. Bruce H. Stover, Marengo, has located in Spencer.——Dr. Daniel W. Jackson, Villisca, has sold his practice to Dr. W. W. West, Hepburn.——Dr. J. Jackson Crider, Ottumwa, has located in Burlington.

To Regulate Osteopathy.—The State Board of Medical Examiners has nominated a legislative committee consisting of Attorney-General Mullan, Dr. Alexander M. Linn, Des Moines, Dr. John C. Shrader, Iowa City, Dr. Fred W. Powers, Reinbeck, to formulate a stringent bill to regulate osteopathy or shut it off entirely. Dr. John C. Shrader submitted a report on the examination of the Still College, holding the course was not up to the standard prescribed by the Board.

MAINE.

Board of Medical Registration.—The Board has passed on the papers of the eleven applicants examined at Portland, November 14, and has admitted eight to registration.

School Inspection.—Portland has inaugurated a system of daily school inspection. The physicians appointed for this purpose are Drs. Ralph F. Goodhue, Willis H. Kimball, Henry P. Merrill, Jr., Albion H. Little, William Cammett and Ralph W. Bucknam.

Personal.—Dr. Nathaniel H. Crosby, Monson, has changed his field of practice to Milo.——Dr. John F. Benjamin, Kenduskeag, has moved to Bangor.——Dr. Eugene M. McCarty, Woodfords, has located in Knightsville.——Dr. Percy E. Butler, late of Milltown, N. B., has located in Rolling Dam. ——Dr. A. A. Brown, Southwest Harbor, has moved to Monson.

MASSACHUSETTS.

Diphtheria is epidemic in Lowell; about 90 cases have been reported and an order has been passed appropriating $30,000 for a contagious-disease hospital.

Smallpox is epidemic in Roxbury and South Boston. There are now 250 patients in the isolation hospital and from 2 to 17 new cases are reported every day.——The disease has appeared in Taunton.

Gift to Newton Hospital.—The trustees of the Morse Hospital, Newton, have received from Holis H. Hunnewell a gift of $15,000 in Chicago, Burlington & Quincy Railroad Company 4 per cent bonds, without restrictions as to how the money shall be used.

MICHIGAN.

Free Vaccination.—The Board of Health of Marshall has instructed the health officer to vaccinate free of charge all individuals who were unable to pay.

Unlicensed Practitioner Flees.—An irregular practicing at Center Line, fled on hearing that a warrant had been issued for his arrest on the charge of practicing medicine without complying with the law.

Smallpox.—There are now 23 cases in the county hospital at Houghton.——Seven cases are reported from Elsie.——In several suburbs of Calumet public schools have been closed on account of the disease.

Personal.—Dr. Chauncey L. Barber, Lansing, has located in Calumet.——Dr. Lyston H. D. Pierce, Plainwell, expects to locate in South Africa, and leaves for the seat of war, December 11.

Comparative Morbidity.—For the month of October, compared with the preceding month, pneumonia, pleuritis, whooping cough and diphtheria were more prevalent; and diarrhea, intermittent fever, dysentery, cholera morbus, cholera infantum and inflammation of bowels were less prevalent. For the month of October, compared with the average for October in the 10 years, 1891-1900, scarlet fever, smallpox and measles were more than usually prevalent; and intermittent fever, dysentery, cholera morbus, remittent fever, diphtheria, erysipelas and cerebrospinal meningitis were less than usually prevalent.

Communicable Diseases.—Cerebrospinal meningitis was reported during October, at 4 places; measles at 30 places; whooping cough at 31 places; smallpox at 54 places; diphtheria at 85 places; scarlet fever at 186 places; consumption at 194 places; and typhoid fever at 233 places. Reports from all sources show cerebrospinal meningitis reported at 2 places less; measles at 5 places more; whooping cough at 11 places more; smallpox at 11 places more; diphtheria at 25 places more; scarlet fever at 59 places more; consumption at 1 place more; and typhoid fever at 22 places more, in the month of October, 1901, than in the preceding month.

MINNESOTA.

Grateful Patient.—By the will of John J. Lawless, of St. Paul, $10,000 is bequeathed to his physician, Dr. Charles E. Smith.

Personal.—Dr. Axcel C. Baker, Oronoco, has been appointed to the house staff of Wesley Hospital, Chicago.——Dr. David F. Rae, Pelican Rapids, has moved to Fergus Falls.——Dr. George H. Lowthian has moved from Dennison to Glenville.

Smallpox.—There have been 216 new cases discovered in sixty localities in thirty-four counties. The report of two weeks ago showed only 144 cases. Three hundred is a conservative estimate of the total number of cases at present in quarantine in the state. There are 7 new cases in Chanhassan township, Carver County, and 6 in the village of Barnesville, Clay County. In McCrea township, Marshall County, there are 10 new cases and Norman County has a total of 18 cases. Otter Tail County has a total of 17 new cases, 11 of which are in the village of Pelican Rapids. Polk County has a total of 14 cases, 10 of which have been discovered in Crookston. The village of Starbuck, Pope County, has a total of 18 cases and the village of Red Lake Falls has 39 cases, making a total for Red Lake County of 51 cases of the disease. There are 12 cases in Duluth.

MISSOURI.

Dr. George H. Rushby, who located in Millersburg last spring, has moved to Columbia.

The Coroner's verdict in the tetanus cases charging the St. Louis Health Department with negligence in the care and dis-

tribution of the city antitoxin was not unexpected. The report of the experts, Drs. Fisch, Waldron and Bolton was prepared with great care. There is no question as to the competency of the physician in charge, but the evidence shows that untrained helpers did much of the responsible work in drawing, preparing and labeling the serum, and proper tests were not made before distribution. Meanwhile the public press is urging the fixing of the responsibility and the end is not yet.

Tuberculosis Ordinance.—As predicted, the City Council of St. Louis refused to pass the "tuberculosis bill" as presented by the Health Commissioner. It was urged by the committee of the Medical Society that the proposed general registration of all tuberculous cases and disinfection of rooms would be inoperative and an injustice. A modification agreed upon by the medical members of the Board of Health and the Society's committee will shortly be presented. It substitutes care and thorough cleanliness for the so-called disinfection, and requires that the physician shall notify the Board of Health of each advanced case, where in the opinion of the physician cleansing of the apartment and enforced sanitation is indicated. In other words the physician is made responsible and can call on the Board of Health when needed.

St. Louis.

St. Louis Water Supply.—The question of the pure water supply grows in interest. It will be one of the topics in the Washington University lecture course this winter. There is reason to believe that St. Louis will have a pure water service second to none in the country. Two plans are proposed: one to build a large filtration plant and use the Mississippi River water, and the other, to convey the water from several great springs in the Ozark Mountains. Engineers are making reports on both propositions.

The hospital facilities of St. Louis are being largely increased. The new City Hospital, on the site of the old one, is progressing somewhat slowly, but steadily. The Jewish Hospital in the western part of the city is building, and near it will be the new St. Luke's. St. Anthony's on Grand Avenue, although new, is well patronized, and is one of the best and finest hospitals anywhere. Mount St. Rose, the new hospital for consumptives, is nearing completion and is almost a duplicate of St. Anthony's in size and construction. The Barnes Hospital, with its $1,000,000 endowment, has, for some doubtless wise reason, been held back by the trustees.

NEBRASKA.

Personal.—Dr. George R. Gilbert, dispensary physician at Union Pacific headquarters, Omaha, has been transferred to Cumberland, Wyo., where he is to be surgeon for the coal department of the road.——Dr. Seymour H. Smith, emergency surgeon for Omaha and the bridge district, has assumed the duties formerly performed by Dr. Gilbert.

Complaint Filed.—Health Officer Rohde, of Lincoln, has filed a complaint charging Dr. Charles A. Shoemaker, a homeopathic physician, with violating city law, in the following language: that "while being a physician within the said city did wilfully neglect for more than twelve hours after obtaining knowledge of the same to report a case of contagious disease, to wit: Smallpox, said case having the symptoms of smallpox."

Smallpox.—St. Dervin, Nemaha County, has 26 cases of the disease.——On account of the general re-appearance of smallpox the State Board of Health has issued a circular from which the following extracts are made: "Present indications threaten, for the coming winter in Nebraska, a more widespread and serious epidemic than has been known in the state for many years. It can readily be controlled by proper quarantine and isolation. That it may be possible to locate every case promptly the State Board of Health demands of every practitioner of medicine in the state of Nebraska that he report by letter every case of smallpox coming under his notice within twenty-four hours of his knowledge of said case, such report to be addressed to George H. Brash, M.D., Beatrice, secretary of the board. It is further resolved by the board that failure to make such report shall be sufficient cause for the revocation of the certificate to practice medicine in Nebraska, of the party failing to make such report."

NEW JERSEY.

Smallpox.—Two new cases have been discovered in Newark.

Louis Leroy, B.S., M.D., of Newark, has been appointed State Bacteriologist of Tennessee, and has moved to Nashville.

City Hospital, Newark.—The new City Hospital, Newark, was formally opened, November 12, and turned over to the Board of Health by the Common Council. The hospital consists of a main building with wings and a home for nurses and attendants. It will accommodate several hundred patients and is fitted up in accordance with the most modern requirements.

Tetanus in Camden.—Following the epidemic in St. Louis, nine deaths from tetanus in Camden have caused a panic among the parents of that city. Although vaccination was promptly forbidden, most careful investigation has thus far failed to disclose any connection between the vaccine virus employed and the tetanus which apparently followed the vaccination. Furthermore, no case of tetanus occurred after vaccination within the known incubation period of the disease.

NEW YORK.

Consumption Hospital Site.—The latest rumor from Albany regarding this much-discussed question is that the board of managers of the proposed state hospital for those threatened with consumption had made a positive decision in favor of the Ray Brook site, and it was highly probable the Board of Review would approve of this action. The Ray Brook site is midway between Saranac Village and Lake Placid, in the Adirondacks.

Proposed Union of New York Society and Association.—In his inaugural address as President of the Medical Society of the County of New York, last Monday evening, Dr. Frank Van Fleet said that one of his avowed objects was to promote a friendlier feeling between the members of that Society and the forces now working in antagonism to them, to the end that the spirit of usefulness of the two bodies might be increased and that there might be a thoroughly united profession. With this object in view, he urged the Society to extend the olive branch and exhaust every honorable means to bring about a reconciliation between the Association and the Society. After the address the following motion, made by Dr. D. B. St. John Roosa, was unanimously adopted: Resolved, That the president of the Medical Society of the County of New York appoint a committee of five, of which he shall be chairman, provided a similar committee be named by the New York County Medical Association; that these two committees shall confer with reference to the union of the two organizations and that this committee be requested to report to the Society at the stated meeting in January, 1902, or sooner, in order that this Society may, if desirable, make a recommendation to the Medical Society of the State of New York at its next annual meeting.

New York City.

Dr. Smith Ely Jelliffe has been appointed Visiting Neurologist to the City Hospital.

The new German hospital, Brooklyn, received about $2000 as the result of a benefit concert given at the Academy of Music, November 18.

Lectures on Orthopedic Surgery.—The trustees of the New York Orthopedic Dispensary and Hospital announce that the surgeon-in-chief, Dr. Russell A. Hibbs, will give a course of clinical lectures on orthopedic surgery at the institution, on Monday and Thursday, 5 p. m., from Dec. 2, 1901, to Jan. 2, 1902 (both inclusive). The course will be free to the medical profession and students.

Woman's Hospital Anniversary.—The Woman's Hospital in the State of New York celebrated its 46th anniversary at the Berkeley School, November 21. Addresses were made by Dr. William M. Polk, dean of Cornell University Medical School, and by the Rev. Charles Cuthbert Hall, of Union Theological Seminary. The hospital expenses for the year were $67,966, and the subscriptions $358,368, about $250,000 short of the sum needed for an administration building and a new pavilion, which the governors have under consideration. In all, 836 indoor and 3830 outdoor patients received care.

Buffalo.

Mortality.—The report of the Department of Health for October shows a mortality rate of 14.68 per 1000 per annum. Consumption was responsible for 42 deaths, typhoid fever for 11, and diphtheria for 13.

Dr. Lewellys F. Barker, professor of anatomy in the University of Chicago, addressed the Section on Pathology of the Buffalo Academy of Medicine, November 19, on "The Unveiling of the Cell." He emphasized that physiological chemistry is the science which underlies all branches of medicine.

Smallpox.—Twelve new cases of smallpox have appeared in a densely-populated Polish district of the city. As the cases were diagnosed as chicken-pox and there was no quarantine the

health authorities consider the condition grave, but are doing everything possible to avert an epidemic. One of the patients, a child who had not been vaccinated, died.

PENNSYLVANIA.

Dedication of Hospital Annex.—The Percival Roberts memorial annex to St. Timothy's Hospital, Philadelphia, was dedicated with appropriate ceremonies, November 16.

To Build Hospital.—Meyer Guggenheim, New York, has announced his intention to give $60,000 to the Jewish Hospital Association of Philadelphia, to be used for the erection of a hospital for private patients, which shall be known as the Meyer Guggenheim Private Hospital.

Personal.—Dr. Stephen E. Tracy, who recently completed a two years' term of service as resident in the Kensington Hospital for Women, Philadelphia, will locate in San Francisco. ——Dr. Francis B. Davison, Fleetville, has moved to West Pittston.——Dr. John Beattie, Philadelphia, has opened an office in Lebanon.——Dr. Joseph D. Thomas, Pittsburg, is seriously ill.

Smallpox.—Residents of Sharon Hill refuse to be vaccinated and protest against compulsory vaccination, braving a penalty of $25 thereby.——Chester has three new cases of smallpox.——Shamokin and Coal Township have ten new cases and one death.——Because of the prevalence of smallpox in various parts of the city, it has been decided by the Philadelphia Hospital authorities that general visiting to that institution shall be prohibited until the danger of the epidemic has passed.

CANADA.

Anthrax is quite prevalent near Brockville, Ontario.

Child Insurance and Infanticide.—The Quebec Provincial Board of Health has passed strong resolutions requesting the Government of the Dominion to prohibit child insurance, which they claim leads to excessive infant mortality in that province.

Lockjaw from Vaccine.—The public press reports two cases of lockjaw following the use of vaccine. One case comes from Halifax, N. S., and the other from Three Rivers, Que. The Provincial Board of Health of Quebec does not recommend any other vaccine than the glycerinated vaccine.

The National Sanitarium Association objects to Toronto submitting any by-law to the people in January as proposed for $50,000 for the purposes of a consumption sanitarium, claiming that they had bought a site for the above purpose and were going on with the work.

Montreal General Hospital.—The regular quarterly meeting of the Board was held last week. The report of the medical superintendent, Dr. von Eberts, stated that during the quarter 720 patients had been treated to a conclusion in the public wards of the hospital. Of this number 64 died, 32 of which deaths occurred within three days of admission, making the mortality percentage for ordinary hospital cases 4.65.

Royal Victoria Hospital, Montreal.—When Lord Strathcona and Lord Mountstephen built the Royal Victoria Hospital, they also endowed it and transferred 9000 shares of Great Northern stock as a nucleus of the endowment fund, which then paid a dividend of $20,000. Since that time the road has become such a money-maker that the dividends have been doubled, and the income of the hospital is now in the neighborhood of $40,000 a year from this source alone.

Inspection of Immigrants.—Dr. James Barclay, Montreal, has been appointed medical advisor of the new Immigration Board appointed in that city by the United States government. This Board will meet daily, and all immigrants destined for the United States will undergo inspection by them, and in addition undergo a medical examination by Dr. Barclay. The jurisdiction of this Board will extend from the City of Quebec to Niagara Falls. Trachomatous subjects will be debarred and returned to their native country.

Personal.—Dr. C. B. Keenan, Ottawa, has been appointed surgical pathologist to the Royal Victoria Hospital, Montreal, and is to have charge of the surgical work in the outdoor department. Dr. Keenan was formerly senior house surgeon at the Royal Victoria.——When landing at Digby the other day from St. John, Dr. Montizambert, the director-general of public health, being unknown to the quarantine officers, was obliged to submit evidence of recent vaccination. After exhibiting several scars which were satisfactory to the officers, the Doctor made himself known.

Smallpox is still on the increase at Ottawa. The order calling for compulsory vaccination has been rescinded by the City Council.——Smallpox is prevalent at St. Hyacinthe, Que., and the regular city physician being unable to care for all the patients, has had a physician appointed for each ward to assist him. Another order has been issued by the Quebec Board of Health insisting on compulsory vaccination.——The Canadian Pacific Railway Company, the Richelieu and Ontario Navigation Company and the Grand Trunk Railway Company have issued orders for a general vaccination of all their employes in the City of Montreal. ——There are eleven cases of smallpox in the Civic Hospital, Montreal.

Resignation of Dean Craik of McGill.—Robert Craik, LL.D., M.D., C.M., dean of the Medical Faculty of McGill, after a service of many years, has intimated his desire to retire from office. He will be asked to become a governor of the institution, this distinction being a rare one in the history of this famous university. Dr. Craik has been associated with McGill during the whole of his professional life, and has witnessed the development of the Medical Faculty from a mere school of thirty members to an important department of the University, with a total enrolment of over 500 students, in medicine alone. He matriculated in 1850 and was graduated M.D., C.M., in 1854, with the highest honors in his class. In 1889, on the death of Dr. R. Palmer Howard, he was appointed to the deanship. He holds the chair of hygiene and public health. Dr. Girdwood, professor of chemistry, is senior professor in order for the position, although the name of Dr. T. G. Roddick, M.P., has been mentioned in connection with the position.

LONDON LETTER.

The London School of Tropical Medicine.

At the opening of the third session of the London School of Tropical Medicine, Lord Brassey delivered an opening address in which he showed the great and rapidly-increasing importance of this new institution and the necessity for more funds. The Colonial Office has contributed $17,500, and the India Office $5000. The school was originally intended for the instruction of surgeons in the colonial and Indian services, but private students, missionaries and physicians have been admitted. The demand for instruction in tropical medicine is much greater than was anticipated. During the last session it has been necessary to refuse several students. About $500,000 is required to place the school in a satisfactory position. Dr. Patrick Manson said that the students were no callow youths, but men of experience, many of them with gray hairs. Enlarged laboratories, a lecture room and a museum were wanted. He appealed for funds on the strength of the work done by the students. One of them, Dr. George Low, discovered in the West Indies that over 11 per cent. of the inhabitants of Barbadoes were infected with filariæ and that by simple inexpensive measures the disease could be eradicated in a generation. Dr. H. E. Durham is going on behalf of the school to study diseases in the South Pacific. He accompanied Dr. W. Myers to Brazil to study yellow fever. Both contracted the disease, and Dr. Myers succumbed to it. The English government, in spite of its vast tropical possessions, is very niggardly beside the German government in encouraging research. The latter has sent medical expeditions to Brioni (Istria), Lussinpicolo (Istria), German South West Africa, New Guinea, German East Africa and the Marshall Islands, and further expeditions are being planned. On behalf of the London School of Tropical Medicine Sir Francis Lovell, late surgeon-general of Trinidad, is about to undertake an expedition to the tropics to collect funds. He will apply to the British residents in the East and other tropical countries. He will go to India, Ceylon, Straits Settlements, China, Japan, New Zealand and Australia, and will probably return by the United States and Canada.

Typhoid Fever, the Destroyer of Armies, and Its Abolition.

At the United Service Institution, Dr. H. E. Leigh Canney delivered a lecture on this subject. Sir William Broadbent presided, and the lecture was well attended. Examples were quoted of the disastrous effect of typhoid fever on armies, for example, the recent Paardeberg outbreak. The following method of prevention was advocated as absolutely reliable and less likely to error and requiring less skill than filtration or chemical processes. The apparatus consists of a cylindrical copper boiler with a large heating surface below arranged in wedge-shaped pockets and a capacity of 50 pints, an iron stand, and a petroleum lamp, which burns with rapid and complete combustion under air pressure. The whole weighs 38½ lbs.

and measures 33 inches in height and 17 inches in diameter. The apparatus is constructed so as to allow of ready repair if shot through. Cloths are to be used to strain mud from the water. Fifty pints of water can be raised from 54 F. to the boiling point in 11 minutes, three-quarters of a pint of petroleum being consumed. One mule carrying 200 lbs., could transport the following supplies for the unit of 100 men. Two machines in cases with lamps and stands, 42 pints of petroleum (sufficient to supply 4 pints of boiled water daily for each of 100 men for 7 days), sugar, tea, meat extract, vegetable powder, saddle, 2 collapsible buckets and ropes. No water should be drunk not supplied by the "water section." The men working the water section should be specially trained. The advantages of the scheme are: 1, total immunity from water-borne disease which causes four-fifths of the mortality of invading armies; 2, absence of discomfort and inefficiency on the march from minor illness; 3, accessible tea, meat-extract, soup, etc., several times a day on the line of march; 4, enormous reduction of transport. In the discussion which followed the chairman, Major Firth, professor of military hygiene at Netley, Major General Lord Dundonald, Dr. Washbourne, Dr. Conan Doyle and others took part. The lecturer's scheme was highly commended.

Smallpox in London.

The outbreak of smallpox still continues. An average of 12.6 cases are admitted daily to hospital. There are 311 cases under treatment.

Plague.

No fresh cases have been reported in Glasgow or Liverpool since the last report to The Journal. The plague returns from India for the week ending October 12 and 19 show the number of deaths to have been 8551 and 8372. During the corresponding weeks of 1900 the mortality was only a third of this. In Egypt during the week ending October 27 there were only 2 fresh cases, and November 2, 2 cases. At the Cape only one fresh case is reported for the week ending November 2. In the Island of Mauritius, 85 fresh cases and 50 deaths occurred in the week ending November 7.

PARIS LETTER.

Two Cases of Sudden Death from Medullar Cocainization.

Professor Legueu, surgeon of the hospitals, has reported recently at the Society of Surgery two cases of death from medullar cocainization, which took place in his service at the Hotel Dieu. According to Dr. Legueu, no fault could be found with the manner in which the injection was made, nor with the solution used, which was analyzed. The only attenuating circumstance was the condition of the patients. The first one, who was operated for the rupture of the triceps tendon, had had an attack of apoplexy. He was stout and suffering from emphysema; moreover, the heart sounds were indistinct, and and there was atheroma of the arteries. Dr. Legueu felt that chloroform was hardly indicated, and decided unwisely, as he admitted, to use cocain. A little less than 2 cubic centimeters of cocain were injected. Just as Dr. Legueu was opening the articulation to remove the clots of blood, the patient complained of feeling oppressed, and asked to be placed in a sitting position. Hardly had this been done, when his face was convulsed, and he fell back dead, his complexion taking on a dark hue. An autopsy was not performed. The second case concerned a man 61 years old, suffering from strangulated hernia, dating from two days back. The condition was far from good, the pulse being at 140. Dr. Fredet, the chef de clinique, had been called, and he decided to use cocain. Only 1.5 centigrams were injected very slowly. The patient had already been prepared when the breathing began to be labored and vomiting took place twice. The face grew pale; the forehead was covered with perspiration, and notwithstanding two injections of ether death took place only twelve minutes after the injection. An autopsy was carried out. There were no signs of heart disease, but the right lung showed several infarcts of recent formation, about six to eight in all. The kidneys were diminished in size, but the capsule was easily removed. The cortical substance was, however, slightly diminished, not being more than 6 to 8 millimeters thick. The heart had stopped in systole, and as there were no signs of possible uremia, it may well be thought that death was due to syncope, caused by the action of the drug on the bulb. Dr. Legueu added that he considered two deaths out of 200 cases a rather large percentage, and he had decided for the present to refrain from using cocain. He considers that cocain may be sometimes indicated, but there are certain cases where it is best to abstain from its use.

Medullar Cocainization for Operations on the Head.

Such accidents as those described above do not seem to deter some operators from using larger doses, and Dr. Chaput of the Tenon Hospital, has been able to carry out recently operations on the arm and head. The doses used varied from 3 to 4 centigrams. In speaking of one of the operations on the arm, a disarticulation of the wrist, Dr. Chaput remarked that the patient complained of the pain, but did not cry out much. Of the three operations on the head and neck, one was for suppurating tubercular glands, another for removing the styloid process of the temporal, and a third for an abscess of the maxillar region. The dose given in this latter case was 4 centigrams and anesthesia of the chin existed after 14 minutes. Dr. Chaput admitted that analgesia was not complete, and said that it would be necessary to choose courageous subjects for such operations. One must admit that it does not seem quite clear why local anesthesia might not be used as well in such cases. Dr. Chaput recommends the following procedure before and after the injection. The patient should not eat before the operation; an hour before, he should be given an alcoholic mixture with 25 drops of tincture of digitalis and 20 grams of syrup of morphia. An elastic band should be placed around the neck before the injection. The injection should be made quickly, and immediately after 500 grams of saline solution should be injected under the skin of the thigh. All this, according to Dr. Chaput, would diminish noticeably all possible danger. He considers that anesthesia of the head should only be sought by this method when general or local anesthesia by other means are contraindicated.

Guinard's Modification of Tuffier's Technique.

Dr. Guinard claims to have found a means of suppressing all after-effects of medullar cocainization by using a solution of cocain in the rachidian liquid of the patient operated on. He described his technique at the recent Congress of Surgery. He collects 60 to 80 drops of this liquid in a sterilized bottle and adds 6 to 7 drops of a concentrated solution of cocain, about 1 centigram to 2 drops of water. The whole is then injected slowly. Dr. Guinard remarked that he had already carried out 50 operations with this technique, without a single accident. An article by Drs. Desfosses and Dumont was published on medullar cocainization. In a footnote they alluded to this modification of Dr. Guinard, and said: "Dr. Guinard would seem to have performed 50 operations." Dr. Guinard sent a paragraph to the *Presse Médicale* of November 13, in which he said this should be read as follows: "Dr. Guinard has performed over 70 operations without a single post-cocain accident." It is certainly a fact that medullar cocainization has caused a good deal of emulation, if not rivalry, among the surgeons who have employed it. Nothing of late has been heard from Professor Reclus, who showed himself so determined an adversary of its indiscriminate use. One finds that among the physicians of the hospitals as well as the men under them there is still a certain doubt as to its harmlessness, and the argument that they would not care to have themselves operated on in such manner would seem to plead in favor of reserving it for some few special cases.

Medical Knowledge Taught by Theatrical Plays.

There is a tendency on the part of playwrights in France to try to teach the public certain medical facts by means of the theater. Not long ago a play called *Les Remplacantes* showed the evils of employing wet nurses. Still more recently a drama called *Le Baillon*, i. e., "The Gag," was given as a means of showing the results of professional secrecy. A young woman is brought up in ignorance of the fact that she is tuberculous. One lover finds it out before the marriage ceremony takes place and jilts her. Another, who is kept in ignorance, finds it out when it is too late. The unconscious victim of this disease is looked upon as a plague-stricken creature, and wonders why even children are not allowed to embrace her. She at last finds out the secret. The dramatic author, Brieux, has recently finished a play called *Les Avariés, avarié* meaning decayed, spoilt, and in it he shows the danger of luetic contagion in marriage. He is a member of the league against syphilis, recently founded by several prominent medical men, among them being Fournier, and their ideas on this subject are put forth in this play. The public censor forbade, however, the giving of the play before the general public, so a select audience was chosen and the piece read to them by Brieux. There is nothing wrong in itself in the play, but it is to be doubted whether such topics can well be placed before the general public.

No Case of Bubonic Plague as Yet in France.

There has been quite a discussion at the Academy of Medicine on the quarantine inflicted on the passengers of the

Senegal. Dr. Bucquoy, who was on board, made some remarks on the lack of serum on board the boat, to which is due the death which took place. According to Dr. Proust, who is one of the best-known hygienists in France, it is impossible to oblige any but emigrant ships to carry serum. According to Dr. Debove, there is no lack of funds, as the state has not used half the amount which results from sanitary taxes. Dr. Monod made the remark that so far no case of plague had been seen in France, whereas in England, Scotland, Italy and Portugal there had already been several.

Professor Debove Chosen as Dean.

Professor Brouardel, who had filled the position of dean of the Paris Faculty for fifteen years, has just resigned, and his place has been taken by Professor Debove, who was named professor of clinical medecine when Potain retired.

Correspondence.

Reception of Professor Senn and His Companions in Tokio.

TOKIO, JAPAN, Oct. 25, 1901.

To the Editor:—I hope by this correspondence that our American professional brethren will understand that we Japanese medical men appreciate what is being done now in the United States for the advancement of Medicine. We were pleased to have received a visit from Drs. Nicholas Senn, Daniel R. Brower, Jacob Frank and William M. Mastin, while they were encircling the globe.

On the evening of the 27th a dinner was given in honor of the distinguished guests by the members of the Medical Profession in Tokio, Dr. Mastin being, much to our regret, detained in Yokohama on business, and a large company assembled, dinner commencing at 6:30. The hall was beautifully decorated and on the *menu* cards the flags of the United States and Japan were crossed in amicable folds. Baron Hashimoto proposed the health of our visitors, which was drunk with enthusiasm, after which Dr. Kitasato, of bacteriological fame, delivered an address in German, of which the following is a short abstract:

"Meine Herren! Es ist eine Ehre für uns, dass wir heute den berühmten Chirurg aus Chicago willkommen heissen, ich meine Herrn Prof. Dr. Nicholas Senn. Wir Japaner sind den Herren Amerikanern sehr dankbar für die Civilisation unseres Vaterlandes, denn der erste, welcher das geschlossene Thor Japans geöffnet hat, war der damalige amerikanische Commodore Perry; seither sind wir so weit gekommen, dass auch Japan zu den civilisirten Ländern der Erdoberfläche gehört.

"Vor einigen Monaten haben wir hier zwei grosse Forscher unter den amerikanischen Medicinern kennen gelernt, nämlich die Herren Prof. Dr. Mitchell und Prof. Dr. Keen, und jetzt zum dritten Male ist unser hochgeehrter Herr Prof. Dr. Senn bei uns; es ist das Zeichen, welches auch die Medicin zwischen Amerika und Japan in nähere Verbindung bringt.

"Meine Herren! Sie gestatten mir also, dass ich mein Glas erhebe und ein Hoch ausbringe auf Herrn Prof. Dr. Senn. Herr Prof. Dr. Senn lebe hoch, hoch und noch einmal hoch!"

The next speech was delivered in English by Dr. S. Suzuki, Deputy Surgeon-General of the Japanese Navy. After referring to the many interchanges of amicalities between the United States and Japan, and to the recent courtesy of the U. S. Government in sending a fleet to the unveiling of the Perry Monument at Uraga, he expressed the hope that the medical relations between the two countries might become closer. Japanese students of medicine have hitherto generally gone to Europe for study, but in no country had medical science made such strides as in America, and it was an honor to them all to welcome so eminent an exponent of American science as Dr. Senn, whose works on various branches of surgery and on the military surgery during the late Spanish-American war were well known to Japanese students of military science. He hoped that the medical bonds between the two countries would be drawn closer.

Dr. Tomatsuri then rose and spoke of the time when Dr. Senn and he had been thrown together in Cuba and Porto Rico during the Spanish-American war, and was glad to have this opportunity of publicly recording his gratitude for the great kindness he had received from Dr. Senn at that time. He had done his best to introduce Dr. Senn and his friends to everybody present; but he was sure that Dr. Senn would not remember all their names. He therefore took the liberty of presenting him with a list containing the names of all the company present, and hoped that Dr. Senn would accept it as a reminder of his many friends in Japan. Dr. Senn, in reply, spoke first in English and then in German. He had been much pleased, as every traveler is, with the natural beauties of the country in which he was traveling. Since coming to Tokio, he had been not only pleased but impressed with the evident progress of medical science. He had visited medical colleges, institutes, hospitals, all of which seemed to be perfectly organized, but what had struck him most was the completeness of the laboratory accommodation attached to these institutions. The Red Cross Society, too, had impressed him very much, and as a foreigner he felt pround to stand before them with the badge of the Society on his breast. He should have a great deal to say to his medical friends in the United States about the progress of this Society, and he felt sure that the Imperial Princes and Princesses, Barons Ishiguro and Hashimoto and all the other ladies and gentlemen connected with the Society deserved much praise for their successful work of charity. The flags of Japan and America had often been crossed before in token of amity, but never before, he believed, on any occasion connected with the medical profession. He took it as a good omen for the progress of medical science in both countries, in the light of the rising sun by day, by the light of the twinkling stars by night. He concluded by expressing his warmest thanks to Surgeon-General Baron Saneyoshi and to Fleet Surgeon Tomatsuri, but for whose kindness he would have been unable to get the thorough knowledge of Tokio medical work which he had now obtained.

Then, speaking in German, after reiterating many of the sentiments expressed in his English speech, he regretted that the time was too short to enable him to make their better acquaintance as he would leave Yokohama the next day. The dinner came to an end about 8:15 p. m. After a short conversation in the drawing room, our guests took their departure to catch the 9:20 train for Yokohama. Professors Kitazato and Sato, Deputy Surgeons-General Totsuka and Suzuki, and Fleet Surgeon Tomatsuri, accompanied them as far as the depot. The party left Yokohama for San Francisco per *America Maru*, at noon, September 28.

DR. B. TOMATSURI,
Fleet Surgeon I. J. Navy.

"A Place to Clean the Teeth Needed in Railroad Car."

PITTSBURG, PA., Nov. 23, 1901.

To the Editor:—The communication of Dr. Henry D. Fulton in THE JOURNAL of November 9, on the needs of a proper place for cleaning the teeth in the toilet room of sleeping cars, and your own observations on the subject, in the same issue, are most timely and important.

While every traveler with any sense of refinement must have regarded this filthy practice with disgust, that is, the spitting and cleaning of the teeth in bowls that are used for washing the face, it is strange that no protest has been entered against it or remedy suggested. Surely the ingenuity of the modern car-builder could quickly devise a remedy if the public would only insist on it. I have not for many years used these bowls nor any other bowls in public places for washing purposes, but always wash with the running water from the spigot.

However, in the sleeping car this can not be done, as you have remarked, as the spigot is too near the bowl, and the water will not flow continuously. My method is simple, and is doubtless resorted to by many other travelers. It is the following: Take a clean towel and soak the half of it under the spigot of the drinking water tank, being careful to let no part of it touch the marble slab. The face and neck can then be washed very comfortably and refreshingly with this wet towel, which can be wrung out over the bowl and again saturated as

often as desired. Besides this, one has the delightful satisfaction of knowing that he is not being contaminated with filthy things.

Can you not bring Dr. Fulton's brief but forcible letter to the attention of the sleeping-car companies?

SAMUEL AYRES, M.D.

Cause of Asthma.

DEPEW, N. Y., Nov. 18, 1901.

To the Editor:—In your report of the meeting of the New York State Medical Association last month, you stated that my "idea is that asthma arises from an inability of the blood to carry the requisite quantity of oxygen," whereas I claimed that this abnormality of the blood causes but one variety of asthma, the asthmatic anematosis. The dyspnea in the other varieties of asthma, i. e., the asthmatic lymphocytosis and the asthmatic toxic leucocytosis, is due largely to a tubular obstruction from the disintegration of an unstable blood, which in the lymphocytic variety fills the air tubes with lymph and mucus; that together with the collateral engorgement of the lymph capillaries nearly closes the lumen of the air tube, while in the toxic leucocytic variety the glands in the larynx and air-tubes are enlarged, producing the wheeze and dyspnea.

Yours respectfully, G. N. JACK, M.D.

Married.

LOWERY H. BEAR, M.D., to Miss Zella Barnett, both of Vevay, Ind., November 12.

ROY L. CONNOR, M.D., Detroit, Mich., to Miss Daisy B. Wick, at Baltimore, November 14.

WILLIAM L. RENICK, M.D., to Miss Adah Roberts, both of Butte, Mont., November 12.

JOHN A. BADGLEY, M.D., Malta, Ill., to Miss Genevieve M. Wright, at Chicago, November 5.

GEORGE C. WEGEFARTH, M.D., to Miss Margaret Wiessner, both of Baltimore, November 14.

ANDREW HENDERSON WHITBRIDGE, M.D., to Miss Madeline Lavinia Gary, both of Baltimore, November 14.

ABRAM BARNES HOOE, M.D., to Miss Eliza Nutt Mitchell, at Irvington, Lancaster County, Va., November 12.

THOMPSON J. TAYLOR, M.D., Richmond, Ky., to Miss Long, Georgetown, Ky., at Irvine, Ky., November 11.

ALEXANDER GRAY FELL, M.D., Wilkesbarre, Pa., to Miss Rena Maud Howe, Green Ridge, Pa., November 14.

LESLIE C. BROCK, M. D., Smithfield, Va., to Miss Annie Lelia Minton, Everetts, Isle of Wight County, Va., November 6.

Deaths and Obituaries.

James F. Alexander, M.D., University of Georgia, Augusta, 1849, died at his home in Atlanta, November 14, after an illness of one month, aged 77. He was a native of South Carolina, but after his graduation located in Atlanta. He was an ardent secessionist and at the outbreak of the war went to the front with the Seventh Georgia Infantry. After six months' service he was assigned to hospital duty in Atlanta. He was prominent in the medical profession and served as a member of the local board of health for ten years, and as its president for several terms; he was also a member and some-time treasurer and president of the Medical Association of Georgia. While serving on the board of health in 1896, during the yellow fever scare, he opened the doors of Atlanta to the refugees, and his contention that the disease would not spread in Atlanta was shown to be correct.

Stuart Eldridge, M.D., Acting Assistant Surgeon, U. S. Marine-Hospital Service, on duty in the office of the United States Consul General, Yokohama, Japan, is dead. He was a native of New Jersey, lived in Waukesha, Wis., for several years, and was afterward connected with the Agricultural Department, Washington. In 1871 he went to Japan with General Horace Capron, and was afterward employed by the Japanese government, and organized hospitals at Hakodate and elsewhere. He was assigned to duty in Yokohama in 1894.

Levi L. Todd, M.D., University of Louisville, Ky., 1856, a member of the American Medical Association and one of the oldest and most esteemed practitioners of Indianapolis, Ind., died at his home in that city, November 16, from heart disease, aged 71. He commenced the practice of medicine in Paris, Ill., in 1858, and moved to Indianapolis in 1874. He was a member and at one time president of the Marion County Medical Society and a professor in the College of Physicians and Surgeons.

Dwight W. Day, M.D., University of Buffalo, N. Y., 1861, died suddenly from apoplexy while reading a paper before the Inter-County Medical Society at Eau Claire, November 19, aged 60. Dr. Day was a native of New York, served in the Civil war as surgeon in the Union army, at the close of the war located in Eau Claire and was at one time mayor of the city. He was prominent as a physician and was a member of the American Medical Association.

Zachary Taylor Harvey, M.D., College of Physicians and Surgeons, Chicago, 1883, died at his home in Council Grove, Kan., November 15, from paralysis, aged 49. He was a native of Illinois and practiced for a time in Brooklyn, Ill., but moved to Kansas in 1887. He was a member of the Golden Belt Medical Society, Kansas State Medical Society and of the American Medical Association.

Samuel Ashhurst, M.D., University of Pennsylvania, Philadelphia, 1861, died in London, November 12, from acute bronchitis superinduced by fog, after a short illness, aged 61. As Dr. Ashhurst was a man of independent fortune, he did not practice for pecuniary gain but his work was among his friends and the poor. He was prominent in philanthropic work of all kinds.

David C. Reynolds, M.D., University of Pennsylvania, Philadelphia, 1852, a practitioner successively in McVeytown and Lockhaven, but for the last 25 years a resident of Philadelphia, died at his home in that city from apoplexy, November 12, aged 71. He was the founder of the Commonwealth Provident Association and its medical director.

C. Juste Touatre, M.D., Faculté de Médecine, Paris, France, 1865, who retired from practice three years ago in New Orleans, and went to France to live, died last month in that country. He will be remembered as the author of a work on yellow fever, published by the *New Orleans Medical and Surgical Journal.*

Richard M. Phillips, M.D., Missouri Medical College, St. Louis, 1852, a native of Kentucky, but for more than twenty years a resident of Topeka, Kan., died at his home in that city, November 15, from heart disease associated with dropsy, after an illness of eleven months, aged 74.

James Irving Marcley, M.D., College of Physicians and Surgeons, New York, 1873, was suffocated in a folding-bed at his residence in Buffalo, November 13, aged 54. For several months Dr. Marcley had not been in active practice but had been connected with a furnace company.

Charles R. Stephens, M.D., Bellevue Hospital Medical College, New York, 1874, formerly a practitioner of Omaha, Neb., but of late years a resident of South Pasadena, Cal., died at Victor, Cal., November 14, from pneumonia.

Wilford J. Bates, M.D., Rush Medical College, Chicago, 1861, a practitioner of Ransom, Hillsdale County, Mich., died suddenly, November 16, from heart disease, while making a professional call at Sibley's Corners.

Agnes Turner, M.D., College of Physicians and Surgeons, Chicago, 1901, died at Epworth Hospital, South Bend, Ind., November 18, from nephritis following typhoid fever, after an illness of nine weeks, aged 39.

Henry A. Morgan, M.D., Medical College of Virginia, Richmond, 1850, died suddenly at Suffolk, Va., November 10,

from heart disease, aged 74. He moved to Suffolk from Gates County, N. C., ten years ago.

D. H. Parker, M.D., Medical College of Ohio, Cincinnati, 1873, died at his home in Medon, Tenn., November 14, after a lingering illness, aged 60. He represented Madison County in the state legislature in 1891.

Mortimer Bainbridge Ruggles, Jr., M.D., one of the resident staff of the Manhattan State Hospital, Islip, Long Island, N. Y., died from acute nephritis, November 15, aged 22. He was ill only one day.

James H. George, M.D., Medical College of the State of South Carolina, Charleston, 1876, a prominent physician of Linden, Marengo County, Ala., died at his home in that place, November 10.

George H. Marmion, M.D., University of Pennsylvania, Philadelphia, 1866, a specialist in diseases of the eye and ear, died at his residence in Washington, D. C., November 12, from apoplexy.

Alexander N. Simpson, M.D., Missouri Medical College, St. Louis, 1878, coroner of Mineral County, Colo., was found dead with a bullet wound in his back in his office at Creede, November 16.

T. O. Linthicum, M.D., College of Physicans and Surgeons, Baltimore, 1883, died near Corbins, Caroline County, Va., November 11, from fever, after an illness of several weeks, aged 45.

Andrew J. Stoner, M.D., Jefferson Medical College, Philadelphia, 1853, one of the pioneers of Decatur, Ill., died at the Jacksonville Hospital, November 13, after a short illness, aged 76.

L. A. Schaefer, M.D., University of Halle, Germany, 1869, one of the oldest practitioners at Schuyler, Neb., was run over and killed by a train at that place, November 15.

Guy Coulter, M.D., Jefferson Medical College, Philadelphia, 1889, a well-known physican of Columbus, Ohio, died at Grant Hospital after a short illness, aged 40.

Charles L. Hormanson, M.D., University of Pennsylvania, Philadelphia, 1881, died from Bright's disease, at Onancock, Va., November 16, aged 43.

Isaac K. Snell, M.D., College of Physicians and Surgeons, New York, died at his home in Brooklyn, November 13, aged 77.

Miscellany.

Sanatorium for Tuberculosis.—The Medical Society of St. Louis City Hospital Alumni on November 21, considered the following resolution offered at the meeting of November 7: Whereas, The provision, by state government, of sanatoriums for the reception and care of tuberculous persons has become an acknowledged necessity for the better protection of the public against tuberculosis in its various forms; and, Whereas, Several states already possess such sanatoriums while Missouri, although the fifth state in the Union in order of population, has taken no step toward providing for the establishment of such an institution, therefore be it Resolved, That the Society of City Hospital Alumni recognizes the urgent necessity for an adequate institution designed for the exclusive care and treatment, both hygienic and medical, of tuberculous persons in the State of Missouri, the said institution to be erected and maintained by the state government. 2. That this society shall at once, by correspondence and otherwise, seek to enlist the active co-operation of other medical societies and bodies, and of the public press throughout Missouri to the end that a sanatorium, commensurate with the importance of the object sought, be authorized by legislative action, the same to be erected in some suitable location in the mountainous part of the state. 3. That copies of these resolutions be transmitted to all other medical societies in the state, to medical colleges, to the medical press and the local daily press, to the governor, and members of the general assembly; and that a persistent agitation of this subject be maintained in order that public opinion may be so influenced as to secure favorable action by the next legislature toward the more effectual prevention and control by approved methods of one of the most destructive diseases to which mankind is liable.

DINNER TO DR. T. GAILLARD THOMAS.

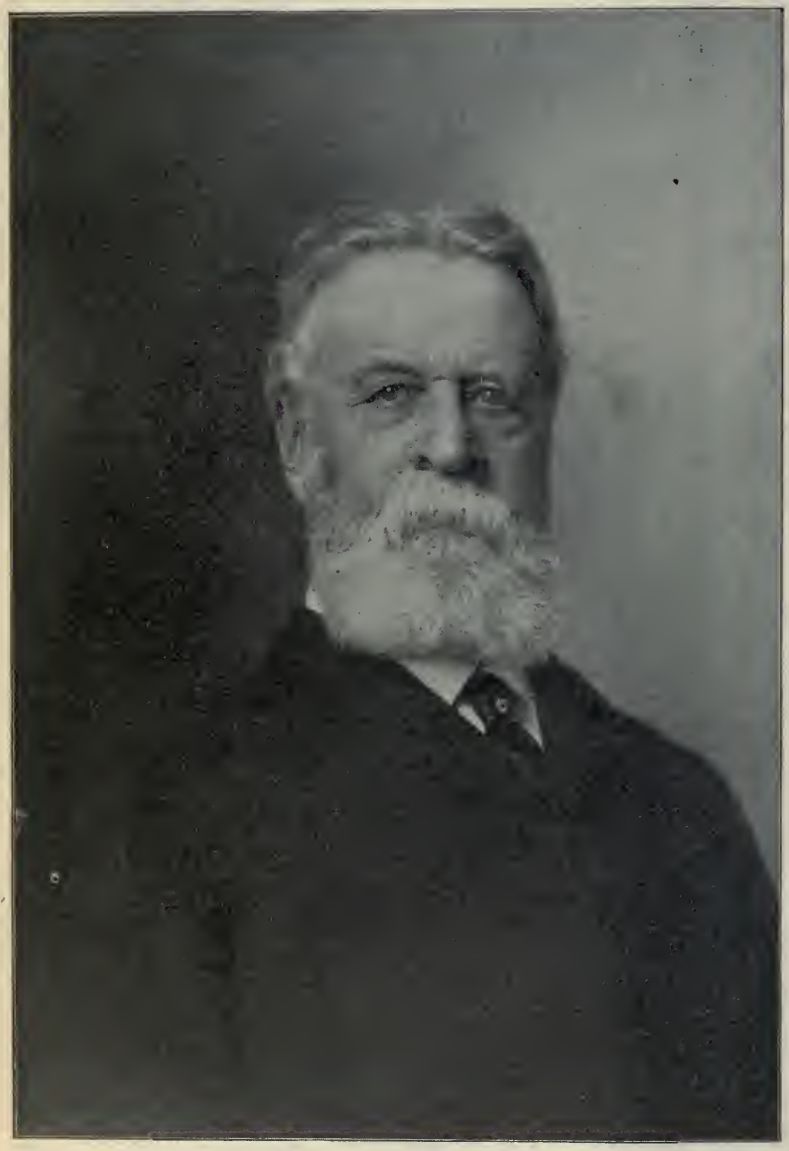
About three hundred members of the medical profession assembled at a dinner at Sherry's on the evening of November 21, to commemorate the 70th birthday of Dr. T. Gaillard Thomas, Emeritus Professor of Obstetrics and Gynecology of the College of Physicians and Surgeons. Dr. Thomas was born on Edisto Island, near Charleston, S. C., on November 21, 1831, and was graduated in Charleston in 1852. Shortly after this he was resident physician at Bellevue Hospital, and later spent some time in the Rotunda Hospital, Dublin. Dr. J. W. McLane, New York, presided at the dinner, and many physicians of prominence were present to do honor to their distinguished and venerable guest. Among those who spoke were Dr. W. H. Welch, Baltimore; Dr. George B. Shattuck, Boston; Dr. S. Weir Mitchell, Philadelphia; the Rev. Dr. D. H. Greer, New York, and Judge Howland, New York.

An interesting incident was the reading of the following letter from Dr. John T. Metcalfe, who is in his 84th year:

"The infirmities you wot of forbid me to join in welcoming our friend Doctor Thomas to the 'Senate of the Seventies.' Let this be my tribute to an occasion that I rejoice to have lived to see, that from the summit of my ancestral years his course, in a life as open to me as to himself, appears as the day-dreams of my own youth. Zealous as an associate, faithful as a friend, in my declining years he has unfailingly sought to repay a debt that was never due by the devoted affection of a son."

In response to the many kind things said about him, Dr. Thomas spoke as follows:

Some men are born egotists; some achieve egotism; and upon some egotism is thrust. In the name of simple justice I declare that if I score a record in this line to-night, the surpassing kindness of those who surround these tables is entirely to blame.



You entertain me at a most charming banquet; invite gentlemen whom princes would be proud to own as sponsors, to speak kindly of my past; and you make me happy by friendly glances which shall be forever engraved upon the tablets of my heart. Even this is by no means the full measure of your kindness to me. Deep down in the depths of the heart of every man of proper feeling, there lurks the desire to have at the close of his career the approval of the fellows of his guild, be that guild a common trade or one of polite learning. You who have borne to me the relation of brother practitioners and have striven beside me, shoulder to shoulder in the keen battle of life; and you, who as students, have judged me as teacher, writer and clinical lecturer, have to-night sealed my past career with the imprimatur of your approval! Than this, no act of yours could have conferred upon me more real pride and pleasure! Through the whole length of a laborious career, which has now reached a half century; in bright periods and in dark ones; in fair weather and in tempestuous; this approval has even been the beacon light upon which mine eyes have rested, the prize for which I have striven. Without it all other success would have been like Dead Sea fruit in my hands, and distinction would have been like dross. Thanks to you, this night will, with its pleasant memories, be ever cherished as the proudest era of my existence!

To-night I feel like an old man who looks into the eyes of his sons and thrills with satisfaction and joy that he has still a hold upon their affections. As I look from face to face I see no strangers here, I see the faces of those whose presence in the college halls has filled me with ambition and urged me on to effort; whose attendance in the hospital wards has brought forth, by their manifest interest, the best that was in me.

As I stand here I look backward down the dim vista of fifty years and see the disembarkation of a young physician of 21, from a coasting schooner from South Carolina, without one acquaintance in this great city, and with a purse no more plethoric than that which usually falls to the lot of the son of a clergyman of the Episcopal church. It is he who now thanks you for celebrating his arrival at threescore years and ten.

As I look I see dimly, like giants enveloped in a mist, the great physicians of the past: the tall, fine figure of the great Valentine Mott, with his classic features and beautiful face; the learned and eccentric John W. Francis; the courteous Delafield, and the erratic Martin Paine; later, the striking and attractive Willard Parker, John Murray Carnochan and Alonzo Clark; and later still, Van Buren, Markoe, Barker, Austin Flint, and the brilliant and accomplished John T. Metcalfe. All gone except the last, who, at the age of 83 years, lives in dignified retirement, surrounded by every blessing for which man can ask in his declining years.

And then my thoughts turn to men of my own period of life. Of these, there were ten young men who clustered as aspirants

DR. T. GAILLARD THOMAS.

for place around the College of Physicians and Surgeons and the University Medical College. They were George T. Elliott, Donaghe, Sands, Draper, Bumstead, Agnew, Otis, Loomis, Budd and myself. Of these ten, nine are gone, and I only remain to recall their names. Truly a half century appears like a long time when estimated by those who have fallen during its passage.

But as I continue my retrospective glance more cheerful reminiscences come to my mind in connection with the wonderful changes which this period has wrought in the science and art of medicine. The science of medicine, founded by Hippocrates in the little Greek Island of Cos, 400 years before Christ, is now 2300 years old! Did it ever occur to you that during the last half century, the fifty years in which you and I have been vouchsafed the great privilege of living, there has been done, for the advancement and growth of medicine, more than was done in the 2250 years which had preceded them? Think for a moment of the wonders which we have seen effected in and for medicine in that time! We have seen the "cellular pathology" of that most eminent of living physicians, Rudolph Virchow, proved true beyond question, and made the basis of a grand and imposing superstructure. We have seen pain annihilated by anesthesia, so that the human body could lend itself without sensation to the perfection of the surgeon's art; we have seen the vision of the physician so magnified in power as to penetrate the opaque walls of the body; and we have seen surgery, thus aided, lifted up from its lowly estate as a mechanic art and placed almost upon the level of an exact science. We have seen the primordial elements of disease, that bacterial host, invisible to the men of old, brought face to face with us by the miracle-working microscope, and by preventing their agency in the production of sepsis, we have minimized the death-rate of surgical operations, and almost stamped out puerperal fever. Working upon the same lines, we have succeeded in rendering impossible forever those appalling epidemics of the Plague, Yellow Fever and Cholera; those pestilences, which for our fathers "walked by darkness" in their gruesome work of decimating the nations of the earth. We have seen the entire field of gynecological surgery, the world over, revolutionized by the eminent labors of Marion Sims, our late associate, and we have seen practical medicine elevated and freed from previous doubt and uncertainty by the wonderful influence of clinical thermometry.

We have detected the true pathology of those obscure cases of so-called idiopathic peritonitis which, from the very dawn of time until our day, have filled year by year throughout the world, not thousands, but millions of graves, and we have experienced an honest pride in seeing a surgical remedy for appendicitis, their true cause, placed upon an enduring basis by McBurney, a son of New York.

Toward the close of the career of the great Napoleon, his followers designated three months "the hundred days of glory"; well may the votaries of medicine, in surveying the results of the last half-century, designate it our "fifty years of glory!" Remember that I have not been enumerating the great advances made in our noble art in modern times, but only giving examples of those which have made glorious these last fifty years. Will you not then join me in grateful thanks that our destinies have been cast in the most glorious and productive half-century for medicine that the world has ever known!

The man who has devoted fifty years of his life to any one subject must have had fixed in his mind some deductions which, upon such an occasion as this, should be worthy of mention. I venture to cite only two. First, as I have grown old in the ranks of medicine the conviction has been borne in upon me with yearly increasing force that the noble art of healing, that art which the Savior of the World delighted to practice, is destined to become in its full development, in spite of the flood of superstition and credulity which on all sides now assails it, one of the chief bulwalks of society; that the wonderful development which has marked the last half-century is a reliable harbinger of the future; and that the improved and developed medicine of that future will constitute one of the chief factors in shaping the progress and civilization of the world.

Do you ask me: "What shall be the sign when these things shall be fulfilled?" I answer: When, in the cabinet of the President of the United States, there shall be a Secretary of Hygiene, whose function it shall be to avail his country of all that concerns the public health. Then will a vigorous quarantine guard every harbor of our land, an active police hunt down those who adulterate our food; and well-appointed laboratories in every state keep careful watch over the water and milk supplies which are now annually responsible for millions of deaths!

Second, my respect for my brethren of the medical profession throughout the world—from the prosperous professor whose home is a metropolis, to the obscure practitioner who plies his arduous calling, trudging the highways with much of labor, and little of profit—has grown with my growth and strengthened with my strength. And the world at large would share my feelings if it knew, as I do, that any one of these men who was willing to barter honor for gold could by so doing exchange a life of labor and of small means for one of leisure and of luxury. In medicine, the diploma imposes honor upon the physicians, even as the gown does upon the priest; and, Glory be to God, the degradation of the one is as rare as is that of the other!

I must not detain you longer except for the purpose of thanking you for your exceeding kindness. But how am I to thank you for it when its very magnitude makes me bankrupt in thanks? In a few moments I shall leave this brilliantly-lighted hall and emerge into the darker streets below. When I do so, I shall take the initial steps that lead into that decade of man's life which an inspired writer declares will surely be attended by "labor and sorrow." Whether my journey in it be long or short, be assured that the memories of this night will serve to lighten that labor and give surcease to that sorrow.

My kind, good friends; my dear brothers, from the depths of my heart I thank you!

A Story by Telegraph.—From the Washington *News Letter Leaflet*, an eddyite publication apparently devoted to the exploitation of the remarkable healing abilities of its editor, we clip the following: Telegram 1.—Earlham, N. Sabin*, 1800 Wyoming Avenue, Washington, D. C.: Fever yet; some better; treat parents for fear. (Signed), ———. Telegram 3.—Earlham, N. Mex., Aug. 15, 1901. *O. C. Sabin*, 1800 Belmont Avenue, Washington, D. C.: Earnest well; stop treatment. (Signed), ———. The use of identical methods for the alleviation of both fever and fear—and presumably fractures would receive the same "treatment"— illustrates the therapeutic possibilities of eddyism as accepted by the deluded minds of the followers of that cult.—*Medical Record.*

Official Tests of Drugs in Belgium.—The Belgian authorities publish in the *Bulletin de l'Hygiene Publique* the reports of the inspectors of drug-stores and pharmacies, without mentioning names. The *Semaine Médicale* quotes certain paragraphs from the latest report which explain the variable results obtained from prescriptions in many cases. It states, for instance, that reduced iron is almost always poor, containing sulphids and only 40 to 60 per cent. of iron instead of the proper 89 per cent. Tincture of iodin seldom contains more than 30 to 40 per 1000 of free iodin instead of the normal 70 per 1000. Similar inspection and reports might be of advantage in other countries, it adds. The medical corps and the pharmacists should be enlightened as to the actual composition of the substances they are using.

Official Inspection of Baby Farms.—The Berlin police department is to appoint at once ten women "helpers," whose duties are to visit the women in their district who board children under 4 years of age, and report any neglect or abuses. The "helpers" are to be paid about $120 each.

Societies.

COMING MEETINGS.

Indian Territory Medical Association, Muskogee, Dec. 3-4, 1901.
Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Thumb (Mich.) Medical Society.—A new organization consisting of the physicians of Huron, Tuscola and Sanilac counties in the "Thumb" of Michigan is being formed by Dr. William Kerr, Bay City.

Arizona Academy of Medicine.—The annual meeting of the Academy was held at Phoenix, November 7. Dr. Ancil Martin was elected president; Dr. John W. Foss, vice-president, and Dr. Palmer, secretary-treasurer.

Clark County (Ind.) Medical Society.—At the meeting of this Society, held at the Reformatory Hospital, Jeffersonville, November 5, Dr. Davis L. Field was elected secretary, to succeed Dr. Jacob T. Davis, deceased.

Wabash Railway Surgeons' Association.—The annual meeting of the surgeons of the Wabash Railway was held in St. Louis, November 14. Dr. Smith A. Spilman, Ottumwa, Iowa, was elected president; Dr. John T. Rice, Attica, Ind., vice-president, and Dr. Christian B. Stemen, Fort Wayne, Ind., secretary.

Maine Academy of Medicine and Science.—The forty-seventh stated meeting of the Academy was held at Portland, November 11. The invitation to send a representative to the first Congress of Medicine for Egypt, was accepted and Dr. Samuel J. Bassford, Biddeford, appointed delegate. Dr. Edwin M. Fuller, Bath, was elected president and Dr. Charles W. Bray, Portland, trustee to succeed himself.

Medical and Chirurgical Faculty of Maryland.—The semi-annual meeting of this body was held at Elkton, Cecil County, November 19. Two sessions were held, the Faculty being entertained at lunch by the Cecil County Medical Society. The address of welcome was made by Dr. Joseph V. Wallace, Chesapeake City. Many papers were read. A discussion on typhoid fever was opened by Dr. William Osler, Baltimore.

Inter-County (Wis.) Medical Society.—The annual meeting of this Society at Eau Claire was saddened by the death of one of its members, Dr. Dwight W. Day, while reading a paper before the society. Dr. Olaf M. Sattre, Rice Lake, was elected president; Dr. Christian Midelfart, Eau Claire, first vice-president; Dr. E. Lewis Fletcher, Augusta, second vice-president, and Dr. Caroline Hedger, Eau Claire, secretary and treasurer.

Sangamon County (Ill.) Medical Society.—The annual meeting of this Society was held at Springfield, November 11. Dr. Lewis C. Taylor was elected president; Dr. Margaret Taylor Shutt, vice-president; Dr. Frank Fisher, secretary, and Dr. Percy L. Taylor, treasurer, all of Springfield. At the conclusion of the business meeting the members enjoyed a banquet in the tea-room of the Leland, at which J. Norman Dixon was toastmaster.

Southern Colorado Medical Association.—The first annual session of this Society was held at Canon City, November 12 and 13, with about 40 members in attendance. Dr. William A. Campbell, Colorado Springs, was elected president; Dr. Robert J. Peare, Canon City, first vice-president; Dr. Benjamin F. Cunningham, Cripple Creek, second vice-president; Dr. Cyrus F. Taylor, Pueblo, secretary, and Dr. J. A. Blunt, Pueblo, treasurer.

Medical Society of the City Hospital Alumni, St. Louis. This Society held its celebration November 4. More than one hundred sat down to a repast at Faust's. Besides the active local members of the Society, there were in attendance Dr. E. H. Gregory, St. Louis; Dr. Julius Kohl, Belleville, Ill., the oldest member of the Society, and Dr. T. Holland, Hot Springs, Ark. Brief addresses were made by Drs. Gregory, Kohl, Tuholske, Grindon and Lewis.

Washington County (Md.) Medical Society.—This Society held its annual meeting at Hagerstown and elected the following officers: Dr. Hamilton K. Derr, Hagerstown, president; Drs. Henry C. Foster, Clear Spring, and John M. Steck, Smithsburg, vice-presidents; Drs. W. Baker Morrison and W. Preston Miller, Hagerstown, secretaries, and Dr. Christian R. Scheller, Hagerstown, treasurer; Dr. C. L. G.

Anderson, Smithsburg, delivered an address from notes taken in the Spanish-American and Philippine wars.

Franklin County (Pa.) Medical Society.—This society, at a meeting held at Mercersburg, elected the following officers: Dr. P. Brough Montgomery, Chambersburg, president; Drs. Oliver P. Stoey, Roxbury, and J. W. Croft, Waynesboro, vice-presidents; Dr. John J. Coffman, Scotland, recording secretary; Dr. H. Clay Devilbis, Chambersburg, corresponding secretary; Dr. David Maclay, Chambersburg, treasurer, and Dr. H. G. Chritzman, Welsh Run, censor. After the business and scientific meeting a banquet was given at the Mansion House.

Birmingham (Ala.) Medical Library Association.—A meeting of the physicians of Birmingham was held November 9 for the purpose of considering the organization of a library association. Dr. John C. LeGrand was elected president; Dr. Dyer F. Talley, vice-president; Dr. William P. McAdory, secretary, and Dr. Robert V. Mobley, treasurer. It is the purpose of the Association to open a library, equipped with works bearing upon the medical and surgical professions, to be open to the members. All the leading periodicals bearing on these subjects will be taken.

Plant System Medical and Surgical Association.—The first annual meeting of the surgeons of the Plant System was held in Savannah, Ga., November 13 and 14, about sixty members being present. Papers were read by Drs. J. N. Baker, Montgomery, Ala.; A. L. R. Avant, Patterson, Ga.; J. E. Lee, and Robert P. Islar, Waycross, Ga.; and Julian C. Woodruff, Charleston, S.C. The latter city was selected as the next place of meeting, the second Tuesday in November, 1902. Dr. Charles R. Oglesby, Waycross, Ga., was elected president; Dr. Julian C. Woodruff, Charleston, and Dr. William R. Chalker, Lake City, Fla., vice-presidents; and Dr. James H. Lattimer, Waycross, Ga., secretary and treasurer.

California Northern District Medical Association.—The eleventh annual meeting of this body was held in Sacramento, November 12. Addresses of welcome were delivered by Hon. George H. Clark, mayor of Sacramento; Dr. James A. McKee, president of the Sacramento Society for Medical Improvement, and Dr. James H. Parkinson, chairman of the Committee of Arrangements. The following officers were elected: Dr. Charles R. Harry, Stockton, president; Drs. John T. Jones, Grass Valley, Moses W. Ward, Woodland, and Edward W. Twitchell, Sacramento, vice-presidents; Dr. Elmer E. Stone, Marysville, secretary, and Dr. Oscar Stansbury, Chico, treasurer. The proceedings closed with a banquet, over which Dr. Frank B. Sutliff, Sacramento, presided as toastmaster.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fourteenth Annual Meeting, held in Richmond, Va., Nov. 12, 13, 14, 1901.

(Continued from p. 1411.)

President Dr. Manning Simons, Charleston, S. C., in the Chair.

SECOND DAY—MORNING SESSION.

DR. E. G. WILLIAMS, Richmond, Va., reported a case of aneurysm of the abdominal aorta which was treated by injections of a solution of gelatin into the intercellular tissue with marked beneficial results.

Closure of Abdominal Incision; with Remarks on Ventral Hernia.

DR. I. S. STONE, Washington, D. C., read this paper. Ventral hernia following abdominal operations is generally due to wound infection and suppuration, with loss of fat and cellular tissue. Hernia may, however, result from imperfect wound coaptation, or may be a result of some accident after operation. It is not infrequently due to enteroptosis, which may prove an obstacle to success, which may defeat all attempts at relief, however well planned. In all ventral hernia the skin and peritoneum will be found united, a condition which doubtless began soon after the wound was closed. Wound infection will usually result in suppuration with loss of tissue, which leaves a space between the parts and also permits the sutures to become loosened. This space is filled with granulation tissue as healing progresses, but an important change has already occurred, namely, the peritoneum and skin are nearer together than before and the separation of the musele and fascia has, perhaps, allowed the entrance of a wedge of peritoneum to enter and to still further separate the walls of the wound. It is easily seen that in this way a ventral hernia is practically assured before the wound has entirely healed, or, at least, before firm union has taken place. In fat subjects the greater liability of wound infection increases the danger of hernia, and in these we have the additional factor of greater intra-abdominal pressure. The author has had excellent results with both buried and through-and-through transfixion sutures. He prefers the latter because the material is sterilized with more certainty and the closure requires less time. He prefers to make the incision in or near the median line, does not avoid the muscle, but divides the fibers directly down to the peritoneum.

One of the precautions taken by the writer is to excise the long flap of peritoneum before placing the sutures. This excessive long flap is not well-nourished, and if allowed to remain favors a collection of blood or serum between it and the muscle in front. In any wound of from three to six inches in length a strip of peritoneum of one or two inches in width may be removed with advantage. This disposes of that portion of the peritoneum which has been overstretched during the operation and which has possibly been infected, and which is not well-nourished. The removal of the flap permits a perfect edge-to-edge coaptation and prevents, to some extent, the wedge of peritoneum, which is the beginning of a ventral hernia.

My First Abdominal Section.

DR. THAD. A. REAMY, Cincinnati, read a paper with this title. The operation was done in February, 1864, at the patient's house. She was 60 years of age; married; the mother of three children. The cyst removed proved to be multilocular, weighing with contents, 46 pounds. The incision was made in the median line, and was five inches in length. Adhesions to the parietal peritoneum were extensive and at many points comparatively firm. On their separation, which was done by the fingers, sponge and handle of a scalpel, considerable and persistent hemorrhage supervened. Before attempting to deliver the tumor it was tapped with an ordinary trocar, and patient turned upon her side to deliver the fluid into a vessel. The pedicle was ligated en masse by a heavy cord of shoemaker's thread (not silk). One interesting feature was the manner in which hemorrhage was controlled in this case. Regarding this point Dr. Reamy says: "The weather was cold, with an abundance of clean snow on the ground. I ordered some brought in. Compressing it with my hands into firm balls, it was held against the bleeding surfaces. The bottom of the pelvic cavity soon contained quantities of water from the melting snow, mixed with blood. This was sponged out and the compression with snowballs continued. In a comparatively short time, to my delight, the hemorrhage ceased; when I dried the cavity with sponges, and closed, without drainage, except what could be secured by the ligature already referred to, which was left protruding from the lower angle of the abdominal incision. The abdominal incision was closed by through-and-through sutures of the same material and size as that used for ligating the pedicle." Patient made an excellent recovery.

Some Avoidable Causes for Disaster in Appendicitis Work.

DR. ROBERT T. MORRIS, New York City, read a paper on this subject. Among other things, the author said: If we step out upon the street and get ten healthy policemen, and put half a yard of gauze into their abdominal cavities to-day, we shall find at the end of a week that "we did not get them in time." That is an excuse which is so often offered when we try to make a weak and poisoned appendicitis patient bear what strong men can not bear. If, in addition to the mechanical insult offered by gauze packing, we add the chemical insult of iodoform, we should have still fewer of these policemen in time. They would have what most house surgeons would call septicemia. The differential diagnosis between septicemia and dangerous iodoform poisoning is difficult to make, excepting on the objective evidence offered by the presence of

iodoform in the wound, the presence of free iodin in the urine, and a wound of healthy appearance while the patient is failing. In insidious iodoform poisoning the wound looks well while the patient does not. In septicemia neither the wound nor the patient looks well. That is a constant diagnostic difference. Gauze packing shocks the patient, lessens his natural resistance, and consequently interferes with his manufacture of phagocytes. Treatment of to-day should avoid interference with the patient's ability to furnish abundant leucocytes. Accessible statistics show us that we do not need to employ gauze packing in our appendicitis work.

Extensive and multiple incisions lessen the patient's ability to furnish leucocytes for the occasion when all of his natural protective powers need to be respected by the surgeon. A beginner needs a great deal of room at the patient's expense, but it is in the interest of the patient to work chiefly by the sense of touch through small incisions. In other words, to come as nearly as possible to letting the patient alone. Another approach toward the idea of letting the patient alone consists in rapid work without much exposure or handling of bowel. Almost any appendicitis operation, no matter what the complications, should be completed in from 15 to 30 minutes. Many a patient who is holding finely to his natural resistance at the end of 15 minutes has lost it at the end of 45 minutes. The idea that the surgeon must get all of the pus out of the peritoneal cavity is out of date. The leucocytes will attend to the matter more effectually. The principle is this: the bacteria and the leucocytes are at warfare with each other in any case of infection. The leucocytes may be almost on the point of winning, but not quite. If we step in and help the leucocytes by removing most of the pus, with its army of bacteria and toxins, the balance of power is transferred to the phagocytes, and they are competent to care for the case, as a rule, if the surgeon himself has not disabled the patient's resistance. It is a constant surprise to see how well appendicitis patients recover, and without post-operative complications if we make the way easy for them. The best way, of course, to avoid disaster is for the surgeon to do the operation before the bacteria have operated very much. Physicians sometimes overlook the fact that the patient is undergoing an operation all of the while that bacteria are at work upon the appendix, so that it really comes to be a question as to who shall be allowed to operate in the case, the bacteria or the surgeon.

President's Address.

Dr. Manning Simons, Charleston, directed attention to the deaths of Drs. Hunter McGuire, of Richmond, and W. D. Haggard, of Nashville, both founders of the Association, who had died during the year. These gentlemen were eminent in their profession, honorable and upright in their private lives, and their death is an irreparable loss to the Association. Speaking of medical societies, he stated that they are the natural outcome of the development of the science and art of medicine and surgery, and for this reason they have multiplied in recent years to fulfill the purpose of discussing propositions bearing on the promotion of more systematic observation and plans of operation, and of greater uniformity in the mode of publishing results, as well as for the consideration of matters on which the co-operation of corresponding societies is desired. To the wonderful development of medicine and surgery during the nineteenth century may be traced the increase of such organizations. Private scientific societies have originated chiefly during the past century, the demand for their existence being due to the necessity of increased organization of rapidly developing knowledge and the desire among workers for a common ground to meet, discuss and compare results and collect facts for future generalization.

With reference to qualifications, the speaker said that there should be some provision of a like kind for special examinations to determine the qualifications of those who desire to enter upon the practice of a specialty, and particularly that of surgery and gynecology. In these days of materialism it would seem out of season to speak of the sentimental aspect of medicine, but medicine has certainly had its sentimental side. The times have changed, and physicians have changed with the times. The demands of modern medicine have to a large extent divested the practice of sentiment that formerly surrounded it. It is a question to what degree specialism has led physicians into the paths and methods of ordinary business. Dr. Simons then discussed the relations of the patient to the doctor, and those of the doctor to the patient, saying that they have changed in conformity to the modernized methods of practice.

Second Day—Afternoon Session.

Results Obtained in Sixty Operations for Prostatic Hypertrophy.

Dr. Hugh H. Young, Baltimore, read a paper on this subject. Stimulated by the work of McGill, Belfield, and others, and having performed prostatectomy in ten cases without a death, the author encountered some cases of prostatic enlargement in very old men which seemed to be entirely beyond the reach of a radical operation. On account of these cases he began a trial of the Bottini operation, and the present paper reporting 60 cases is intended to show a comparison of the two methods, and the results he has secured. These cases were classified as follows: prostatectomies, 15; Bottini operations, 40; miscellaneous operations, castrations, etc., 5; total, 60. Taking the prostatectomies, 12 were suprapubic, and 3 perineal. The ages were 4 between 65 and 67, 2 between 60 and 65, 5 between 55 and 60, 2 between 50 and 55, and 2 between 48 and 50. The condition was fairly good in all but 3 cases. Calculus was present in 5 of the 15 cases, and 6 had led catheter lives. In 7 of the 15 cases the hypertrophy was very large; in 3 it was merely a small pedunculated middle lobe. In 11 cases complete enucleation of the entire prostate was made. In some cases the tumor removed was extremely large. Results: 15 operations, with 2 deaths. Both of these deaths should not have occurred. One patient was undoubtedly septic, had pus kidneys, and should not have been operated until later. In the other case death seemed to have resulted from an infection of the breast after submammary infusion. Of the 13 cases still alive, 12 have gone for periods between six months and three and a half years since operation. Of these 12, 10 may be classed as cured, having no prostatic obstruction, and normal urination. Two are perfectly cured as far as the prostate is concerned, but suffer from cystitis and a contracted bladder, which render urination frequent, though much better than before operation. Taking the Bottini operations, 40 in number, 6 have not been followed. The 34 remaining operations were performed on 31 patients, 3 patients having 2 operations each. The ages were as follows: Over 80, 3 patients; between 75 and 80, 3 patients; all of the above cured. Between 70 and 75, 9 patients; between 65 and 70, 6 patients; between 60 and 65, 6 patients; between 55 and 60, 4 patients. In all, 18 patients over 67 years of age; whereas, among the prostatectomy cases, none were over 67 years of age. Of 15 cases over 70 years of age, all are alive and well.

In discussing the Bottini operation, the author brought out the point that the instrument devised by Freudenberg, while an admirable one, should have more than one blade, so that the operator might have choice as to the depth of cut which should be made in accordance with the size of the prostate. The beak of the instrument is much too sloping, so that several cases have occurred in which the beak has slipped into the urethra and caused dangerous hemorrhage, with sometimes death. In order to correct this and other defects, the author has devised an instrument which, like the Freudenberg instrument, but with four interchangeable blades, can be used according to the case, whether the prostate be large or small. With this instrument he has now performed nine operations, using in those cases all of the blades but one, and can testify to the great service of the ability to use some discretion in the size of the blade that is employed in accordance with the prostatic hypertrophy.

Suprapubic Prostatectomy.

Dr. Floyd W. McRae, Atlanta, followed with a paper on this subject, in which he advocated the early resort to this method of treating enlarged prostate rather than palliative

measures or the seemingly simpler operations of suprapubic fistula, vasectomy, orchidectomy, or the Bottini operation. His reasons were that the seemingly simpler operations are followed by mortality disproportionate to their magnitude; that the relief obtained from them is frequently slight and temporary; that the pathologic conditions were not infrequently aggravated, especially by the Bottini operation. He reported three complete prostatectomies done since May, 1901. The point of originality claimed for the operation is the method of draining. He puts in a retention catheter through the urethra, and closes the bladder and overlying tissues snugly around a parachute drainage tube made out of a soft rubber rectal tube with a single opening at the end, by making four longitudinal slits beginning about one-quarter to three-eighths of an inch from the end of the tube, each slit about an inch long and equidistant from each other, around the circumference of the tube. The four sections are then approximated above and below, by means of a small rubber band put through in the form of a Halsted suture with a large needle. As these sutures are drawn taut, the sections are approximated and the ends flared out somewhat like a parachute. When the bladder is closed, this tube is drawn up so that the flared portion is in firm contact with the anterior bladder wall. The overlying tissues are then closed snugly around the tube and one silkworm-gut suture is put through the tube flush with and through the skin to hold it in position. The flaring of the tube enables the surgeon to draw it firmly against the anterior bladder wall, and by means of the suture put through it and the skin it is prevented from protruding too far into the bladder, avoiding the disagreeable bladder contraction that always takes place if the tube is too long. By this method of drainage the outer ends of the catheter and tube are then put into a urinal which is kept between the legs when the patient is lying on the back, or in front of the thigh when the patient turns from side to side. The advantages claimed for this method of drainage are that the patient is kept absolutely dry and is allowed to turn freely in bed, lying on the back or either side. He reported three operations done by this method since May, 1901, together with a complete pathologic report by Dr. H. F. Harris, pathologist, Atlanta College of Physicians and Surgeons, of the specimens removed. The specimens proved to be "leiomyoma," and "leiomyo-adenoma," with increase of connective tissue as the result of chronic irritation. The irritation noticed in the large specimen evidently followed a Bottini operation done a few months previously, and was associated with phosphatic stone. The patient operated upon in May is now entirely free from bladder irritation, passes a good stream, projecting four and a half to five feet by measurement, when the bladder is moderately distended. Bladder holds, under ordinary conditions, eight ounces by actual measurement, and is capable of holding considerably more. Case 2 is still wearing a McGuire plug, but passes urine readily per urethram. Case 3 is practically well, the suprapubic opening closed, bladder clean, and urine passing freely through the urethra without residue.

Median Perineal Prostatectomy; Total Removal of the Prostate Gland.

DR. ALEXANDER HUGH FERGUSON, Chicago, referred to the work of Nicoll, Alexander, Syms, von Dittel, raising objections to each of the methods followed by those gentlemen. He then proceeded with illustrations and the exhibition of instruments to describe his own operation, which is as follows: "The patient is put to sleep with chloroform, and placed in the extra-lithotomy position. The prostatic depressor is inserted into the bladder through the urethra, and handed over to a trusty assistant. A sponge is pushed into the rectum to prevent the escape of liquid feces. The middle finger of the left gloved hand is then introduced into the rectum and pressed against the urethra at the junction of the membranous and prostatic portions; a long narrow-bladed knife is passed into the perineum through the raphe in the median line, two inches in front of the anus, until it reaches near to the tip of the finger in the rectum, and with one stroke all the structures are cut through to the prostate, without injury to the urethra, prostate, rectum, or anal sphincter. The surgeon should refrain from doing this in his first cases. The skin incision is now enlarged, if necessary, for the introduction of two fingers. Place suitable retractors, one on each side, into the wound, and by blunt dissection expose the prostate, and with the depressor in the bladder it is forced into the perineal wound. Open the capsule with knife or scissors in a transverse direction sufficiently to admit one or two fingers. Place the retractors within the capsule. This is important because traction made on them drags the gland still farther into the wound and holds it firmly while enucleation and extirpation are being performed. It is experienced that by traction from below and depression from above the prostate is fixed, within easy reach, for its entire removal. Enucleate with the finger and bite away the portions thus liberated with the prostatic forceps, until by piecemeal the prostatectomy is completed. No effort is made to save the posterior portion of the prostatic urethra. Indeed, injury to it can not be avoided when the entire gland is removed. While morcellement is in progress, it is advantageous to advance the retractors within the capsule, and introduce the middle finger into the bladder. The forceps can be rapidly thrust between the two fingers to the object to be removed by them, without any danger to the surrounding structures, for when the instrument is closed, its end is perfectly smooth and round. The lateral lobes can be reached to any extent without damaging the mucous membrane of the bladder, and prostatic projections of the middle lobe into the bladder are detected and removed without difficulty. Flush out the bladder very thoroughly with a weak antiseptic solution. A large stream of water must be used, for the ordinary irrigating toy generally used only does harm. Mop out with gauze any water that is in the bladder and wound, and introduce a drainage tube, surrounded with iodoform gauze, through the wound into the bladder. A couple of horsehair stitches closes the part of the skin wound not occupied by the tube, and at the same time prevent the gauze from coming out too soon. Remove the sponge from the rectum, place a comfortably firm dressing over the perineum, and let it be held by a T bandage. Now, attach a long rubber tube to the external end of the drainage tube, and the toilet of the operation is finished. If the patient's urine has been scanty or should he show depression or shock, then it is better to introduce two or three pints of normal salt solution, at a temperature not less than 115 F., beneath the skin, while he is still in the operating room, than to wait until he is taken to his bed."

(To be continued.)

SAN FRANCISCO ACADEMY OF MEDICINE.

Regular Meeting, held Oct. 22, 1901.

Dr. D. W. Montgomery in the Chair.

Epithelioma of the Upper Lip.

DR. D. W. MONTGOMERY presented a case in a man 62 years of age, who first consulted him November 8. His family and personal history were good. Fifteen years ago a growth had appeared on the vermilion border of the right side of the upper lip, where was now a scar. This scar, which was pliable, soft, and healthy-looking, lay a couple of lines from the right angle of the mouth, and was the result of an operation for the removal of the above-mentioned growth, about eight years ago. Soon after the removal of this growth, another appeared on the vermilion border of the left side of the lip, where there was now an immense ulcerated patch with raised rolled borders and deep induration. Within the upper border of this ulcer there was a large cutaneous horn which was of comparatively recent growth, and did not precede the ulcerated surface. Within the last two or three years another growth had appeared on the vermilion border of the upper lip to the right of the median line, but well removed from the above-mentioned scar. This growth, previous to commencing treatment, was oval, well circumscribed, raised, indurated and had a surface dotted with milky spots. Neither of the growths on the upper lip were either painful or particularly tender. The patient was

This treatment had already had a marked effect on the smaller growth to the right of the median line which was flattened out and looked much better. He thought the larger ulcer was also improved, but not so markedly as the growth to the right of the median line.

Congenital Dislocation of the Hip.

Dr. H. M. Sherman presented a case in a boy. In 1897 he had reported some 15 cases of bloodless reposition of congenital dislocation of the hip, but that, of the whole, only two had remained in place. The boy presented was one of the two, and he had a practically normal hip, though not an anatomically normal joint. The manipulation was in most particulars that of Lorenz. The leg had been lame and the joint stiff for some months after the operation, but had gradually improved. Curiously the leg of the dislocated side was now longer than its mate by 1.75 cm.

Bone Filling with Amalgam.

Dr. J. Henry Barbat reported a case. The patient's trouble began in 1886 with pain in the left ankle followed by ulceration and the gradual breaking down of a portion of the shaft of the tibia, which he operated upon in 1898 by removing all diseased bone, but the result was not successful, and he sought relief from the author in September, 1899, who found after curetting thoroughly that he had a cavity measuring nearly 5 cm. long, over 2 wide, and fully 3 deep. After the cavity was thoroughly cleaned out and dried copper amalgam was pressed against the bottom and sides until the whole surface was covered, leaving a hole which was partly filled with dental cement, the top being covered with more amalgam. The cement was used to lessen the weight of the filling and was completely covered with amalgam. The skin was sewed over the filling and dressings applied. The immediate results following this were very good, the pain ceasing and the patient being able to walk around without crutches for the first time in several months. The wound did not completely close, however, and in August, 1900, the amalgam was removed and the bone found in good condition, except at the upper end of the cavity, which was curetted and the cavity filled with formalin gelatin, and after one month it showed a clean, healthy granulating surface, into which the skin had dipped down until the cavity has been covered entirely with new skin and the patient was discharged cured in January of this year.

Removal of Tongue, with Result.

Dr. E. Rixford presented a case as an example of remote result after excision of the tongue. The patient at the age of about 42 came to Cooper College Clinic in the summer of 1900 with a typical epithelioma of the tongue. Operation was advised, but he put it off for some time. He finally came back and the doctor removed the left half of the tongue back as far as the fauces. Recurrence took place, and on March 17 last he removed the entire tongue by Kocher's method, opening the neck on both sides to remove enlarged glands and to tie the lingual arteries at their origins. Some of the glands showed metastases, but many others showed only inflammatory enlargement. He performed a tracheotomy on acount of the deep dissection and the embarrassment to breathing. The patient took the tube out himself on the fourth day and left the hospital on the seventh and went home. He was rather ingenious in the manner of taking food, but was obliged to confine himself to liquids. He took a quantity into the mouth and then throwing his head back was able to swallow it. His general health was good and he had no pain, and no evidence thus far of recurrence. He talked rather well, having learned to substitute labial for lingual mutes. The tongue was removed at the hyoid bone, leaving the epiglottis. The floor of the mouth was rather interesting, owing to the form of the cicatrix. The tumor was atypical squamous epithelioma of the tongue.

Gallstones, with Gangrenous Intestine.

Dr. Rixford also reported the following case: A large man, 53 years of age, weighing 225 pounds, had had more or less trouble in the abdomen for eight years; three years ago he had a very severe attack of gallstone colic in which he passed a number of stones. Since then he had had more or less pretty continuous pain in the abdomen just below the xyphoid. One morning he had sudden pain below the umbilicus, so severe as to cause him to take considerable doses of morphin. He had no chill, but vomited after taking the morphin; pulse 90. temperature 99. Next day pulse was 100, and temperature 100; spasm of abdominal muscles especially in region of appendix; local tenderness very great. The third day, pulse was 120, and temperature 100 in the morning, 128 and 100.5 in the evening. On fourth morning pulse was 144 and temperature 100. He was brought to the hospital and prepared for operation. Examination showed great tenderness over lower half of the abdomen, more on the right side, leucocytosis 11,400, expression anxious and indicative of great suffering. There was apparently peritonitis most likely from the appendix, though jaundice was present and there was a history of gallstones. There was complete obstruction of the bowels. there having been no passage of feces or even of gas since the onset of the pain, three days previously. Under anesthesia the abdomen bulged noticeably on the right side, and a definite tumor could be felt in this region. Incision in the right semilunar line showed a loop of the small intestine gangrenous for ten or twelve inches, the gut being deeply congested for perhaps a foot on either side. This condition of the bowel could not have been produced by any hernia or internal strangulation, but only by obstruction to the blood supply, probably the superior mesenteric artery. The gall-bladder contained a number of calculi. In order to remove the piece of intestine. the mesentery was cut across—it did not bleed opposite the gangrenous portion—and the loop of bowel was simply hung out of the wound in the dressings in the expectation of removing it as soon as adhesions had made the peritoneal cavity safe, and the remainder of the wound was closed. This course was chosen in preference to a resection of the bowel, because in the first place the patient was in poor condition to endure a longer operation, and secondly, because there was no line of demarcation between sound and diseased intestine. The intestine was removed in 24 hours and an attempt made to wash out the ends of the intestine with salt solution, and a pint or more of strong solution of magnesium sulphate was injected into distal and proximal ends with the result of removing from the proximal end a quantity of fluid feces. Soon after the patient rapidly sank and died. The autopsy made by Dr. Ophuls accounted for all the symptoms and showed the reasons for difficulty in this diagnosis, and that the prognosis was necessarily unfavorable.

The case was of particular interest because of the condition of the intestine, which was shown to be due to thrombosis not of the mesenteric artery, but of a principal radical of the portal vein.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Oct. 23, 1901.

President, Dr. Christian Fenger, in the Chair.

Trional Fatalities.

Drs. Archibald Church and E. B. Hutchinson contributed a joint paper on this subject. The authors detailed an interesting case of trional poisoning, which terminated fatally.

Dr. Church stated, in discussion, that nearly twenty cases of death from this drug, administered in so-called medicinal doses, could be found in recent periodical literature; yet one of the most recent text-books on therapeutics states that trional may be given in doses up to 60 grains in twenty-four hours. In none of the cases that have terminated fatally has more than 30 grains within twenty-four hours been administered. Death followed the administration of 20 grains of trional in one case in two doses. In the case reported by them, the dosage never exceeded 30 grains within twenty-four hours. He is not using trional so frequently since this unfortunate experience.

Dr. Harold N. Moyer thought trional was less toxic than sulphonal, which is markedly toxic. He mentioned one case

of sulphonal poisoning that recovered. The majority of cases of sulphonal and trional poisoning that have presented hematoporphyrin in the urine in considerable quantities, have died. There is no question as to the grave toxemias that result from the use of these drugs. The reports of fatalities are sufficiently numerous to warrant him in his own practice in not using trional or sulphonal as hypnotics, and he has not employed them for more than a year and a half.

DR. SANGER BROWN said he had given trional, sulphonal, phenacetin, and that order of drugs a thorough trial, but was soon convinced that they were far inferior to chloral, hyoscyamus, hyoscin, etc., and he had adhered to the latter.

DR. A. W. BAER expressed the hope that the members would look over the death certificates and find out how many people have been killed by taking the coal-tar products.

Colpeurynter in Obstetric Practice.

DR. JOSEPH B. DE LEE said that Carl Braun in 1851 invented the colpeurynter, though hollow tampons, usually pig's bladders, had been used before this by Chiari, Stein and others. Grenser modified Braun's bag, and many others have been devised. Up to 1883 the bags were put in the vagina, then Schauta recommended them for the uterus. Then in 1887 Maurer recommended that traction be put on the tube so as to exert pressure on the cervix from within. The mode of application is simple: After careful antisepsis the bag is filled with sterile water or antiseptic solution, all air gotten out, the bag then emptied, folded into a narrow roll, inserted in the vagina or uterus, and filled with a Davidson syringe; traction is applied or not as indicated.

Indications.—1. Induction of premature labor; claimed to be safer and surer than others; has been used with success by writer in contracted pelves, placenta previa, eclampsia, nephritis, hyperemesis. 2. To hasten delivery, as in eclampsia, premature detachment of placenta, heart disease, etc. It evokes pains, softens the cervix, dilates same gently and firmly from above and makes delivery possible in a short time. 3. To prepare the parts for rapid delivery, e. g., after symphysiotomy, version, or before forceps deliveries in primiparæ, thus the child is like a second twin and the birth is rapid and without injury to the parts. 4. Stenosis and rigidity of the cervix, vagina and perineum. 5. Weak pains; if a cause can not be found, or is not removable, the bags are of real service in evoking strong contractions. Almost always weak pains are a symptom of some underlying cause: 6. In "dry labors" the bag, put inside the uterus, replaces the bag of waters almost perfectly, and may save many hours of labor. 7. In transverse presentation to keep the shoulder from wedging into the pelvis while waiting to be able to do version, and in contracted pelvis for the same purpose, the metreurynter is valuable. 8. When the cord prolapses with the head it may be pushed as high as possible into the uterus and the cervix stopped with a rubber bag. The writer suggests putting a stout drainage tube alongside the cord to save it from pressure. 9. During pregnancy, to lift up a heavy uterus causing hyperemesis, and to replace a retroflexed, incarcerated uterus, filling the colpeurynter with water or mercury. 10. In placenta previa; perhaps the most valuable of all.

Maurer in 1887 used intra-uterine colpeurysis, with traction, and drew attention to the value of the procedure. Dührssen put it on a scientific basis. Bag is placed inside uterus, on fetal surface of placenta and constant traction made on tube. The hemorrhage is stopped by the pressure of the placenta against the open sinuses, pains are evoked, the cervix is dilated gently and evenly, and time is given to rally the patient from collapse, to send for counsel and help. When the bag is passing through the cervix, all preparations are made for delivery, for version, etc. As soon as the bag has passed the external os, which is easily determinable, it is rapidly drawn through the vulva and further procedure instituted, which may take the form of forceps, version, another bag, or perhaps even expectancy. The writer is convinced that extended use of the metreurynter in placenta previa will reduce maternal and fetal mortality to about almost nothing.

Anterior Vertex Presentations; Their Complications and Treatment.

DR. GUSTAV KOLISCHER called anterior vertex presentations those presentations in which the fetal head passes through the pelvis slightly deflected, so that the anterior part of the cranium represents the lowest point of the skull. In cases of pendulous abdomen, where the fetus is the possessor of a struma, anterior vertex presentations are most likely to occur. Some authors claim that uniformly round heads, especially combined with a flat or uniformly contracted maternal pelvis, furnish the majority of these presentations. By means of external examination the resistance, which is formed by the fetal back, is closer to the median line, and not quite as distinct as in normal occipital presentations. Should the anterior vertex presentation persist for any length of time, the elongation of the occiput can be palpated through the abdomen. Internal examination shows that the anterior and posterior fontanelles are on the same level, or that the large fontanelle is even lower situated than the small one. If the head has just passed the pelvic brim, the sagittal suture is encountered toward the promontory, and just behind the symphysis we find an ear or the squamous suture. If the head has descended into the median plane of the pelvis, we find the sagittal suture in one of the oblique diameters, while both fontanelles are still located in the same plane. If normal rotation (occipito-anterior) has taken place in an anterior vertex presentation, the small fontanelle is found just beneath the symphysis, while the large fontanelle can be very easily reached in the perineal region. This is due to the deflection in which the fetal head is held.

If abnormal occipito-posterior rotation takes place in cases of anterior vertex presentation, the glabella rests against the symphysis, while both fontanelles are easily accessible. In cases of occipito-posterior rotation and normally flected head, the large fontanelle lies beneath the symphysis. Once in a while, if the entire fetus is in an oblique position, the small fontanelle can be located higher up than the large one, although the head is kept in normal flexion. In such cases the differential diagnosis could be made by careful and exact external examination, which will reveal the presence of an oblique position of the fetus. As to the frequency of anterior vertex presentation, comparative statistics from recent sources show that it occurs in about eight per cent. of all head presentations.

The descent of the abnormal presentation may vary: Either the head in descending becomes inflected and rotates normally, or it descends to the pelvic floor in a deflected attitude, in which case either normal or abnormal rotation may occur, or the complete descent of the head becomes checked by oblique or transverse presentation. Of course, if normal flexion and rotation occur, the ultimate delivery will in no way differ from any other normal occipital presentation. But if the deflection is not corrected, the passage of the head through the pelvic outlet will be more difficult. If in a deflected attitude of the head the occiput rotates anteriorly, the occipital tuber rests against the pubic arch, and constitutes the point around which the head has to roll in order to pass through the outlet. Thus, the head passes with a larger diameter through the outlet as in normal cases. If occipito-posterior rotation takes place, the glabella rests against the symphysis, and the extrication of the head will be more difficult because it has to be performed from a deflected attitude. Furthermore, we must consider the fact that, as in all cases of deflection, the occiput is elongated, so that the mento-occipital diameter becomes considerably enlarged, thus increasing the difficulty in delivering the head. If an anterior vertex presentation terminates in an oblique or transverse presentation, the whole affair takes on a more serious aspect in primiparæ, and in cases of slightly contracted pelvis, a transverse presentation of the head will, as a rule, not be overcome by the natural forces, even if the head should be normally inflected. One of the above-mentioned presentations, combined with anterior vertex presentation, may be considered an absolute obstacle to spontaneous delivery in primiparæ. The author dwelt at length upon the complica-

tions connected with the class of presentations under discussion.

In all cases of forceps operations in anterior vertex presentation, he thinks the Walcher's posture can be used to great advantage. On account of the unfavorable diameter in which a deflected head has to pass through the vulva, and on account of the enlargement of the mento-occipital diameter, the perineum is always in great danger, and episiotomy has quite frequently been resorted to.

Occipito-Posterior Positions; Their Diagnosis and Treatment.

Dr. Charles E. Paddock stated that a proper appreciation of presentation and position of the fetus in the latter part of pregnancy or the beginning of labor is as necessary as it is to make a diagnosis in any branch of medicine. That this fact is not deemed of sufficient importance is proven by the number of neglected cases which are daily brought to the hospitals or come under the care of the consulting obstetrician. Occasionally the position can not be definitely determined, but such cases are very rare. Familiarity with abdominal palpation will soon place the physician in a position where it will not be necessary for him to be in doubt. The internal examination is hardly necessary to confirm the position or presentation, and unless the os be dilated it amounts to very little, as a rule.

The advantage of making a correct diagnosis of the position of the child in utero is necessary to the correct treatment of the case, and in vertex presentations, when the head is about to engage posteriorly, or has already done so, the condition should be considered pathologic, and the diagnosis should be made early. We have sufficient clinical evidence to establish this fact, and while cases where the occiput is in one of the posterior quadrants of the pelvis, or gravitating that way, are not desirable ones, the author feels that much can be done to correct this position, and thus shorten the labor, alleviate suffering, and lessen the fetal mortality. Authorities differ regarding the relative frequency of the different positions of the vertex, but most agree that the occiput engages in right oblique to a large extent, about 30 per cent. of the cases being occipital right posterior, and about 4 per cent. of this 30 per cent. failing to rotate anteriorly and engaging in the hollow of the sacrum. According to Naegele, who has probably given this subject more attention than anyone else, the head lies in the right oblique in 99 per cent. of all cases. Admitting the frequency of the occiput occupying a posterior position, and knowing the dangers which may result before the case has terminated, it has been the author's experience that the head does not engage as easily in this position as in the anterior one. In O. L. A., for instance, the head enters the pelvis with both parietal bones on the same level, that is, the biparietal diameter of the head passes through a pelvic diameter parallel with and about equal to one of the large oblique diameters. In O. R. P. position, however, this does not occur, and the head passes through a much smaller diameter.

While it may not be possible to correct every case by posture, the number of successful ones is so large that every case diagnosed as O. D. P. before labor should be treated as follows: Caution the woman to lie upon her right side at night, and at all times when she is lying down. Each night and morning she should assume the knee-chest position for ten minutes. If the head be above the brim, in but very few cases will this treatment fail. In this position the anterior wall will be lower, the fetus rotating on its long axis, and the dorsum, being the heavier, naturally will seek the most dependent part of the uterus. The knee-chest position allows the head to settle away from the brim. In taking this position, the abdomen must be entirely free of tight clothing. Take another case, when the diagnosis has been made after labor has commenced, but the head still above the brim, the same treatment is often beneficial. The object of position in these cases is not only that anterior rotation may be favored, but a more perfect flexion of the head may be maintained. If flexion is not secured, we have the sinciputal end nearly on a level with the occiput; entering the pelvis in this way, labor is delayed, and when the head settles down, the sinciput coming in contact with the pelvic floor rotates forward and the occiput engages in the hollow of the sacrum, or we get a deep transverse in arrest which calls for artificial correction. While we speak of the occiput rotating posteriorly, we probably should say the sinciput rotates anteriorly. Hart's law: Whatever position of the fetal body first strikes the resistance of the pelvic floor, whether it encounters this structure behind or in front of the median transverse line it is directed forward, inward and downward under the arch of the symphysis. When the occiput is engaging slowly and the lateroprone position has failed, often much good will result by placing the patient in the Walcher position.

There is still another class of cases where the head has engaged in the brim, the os dilated, but no progress being made. In this class the treatment to be first attempted is one which will nearly always succeed. To illustrate, he reported a case seen by him in consultation during the past week. Mrs. M., white; iv-para; previous labors normal, in labor at term. Labor had progressed for twelve hours, with os fully dilated, membranes ruptured, and head wedged into brim. Forceps delivery had been attempted. In making an examination per vaginam he found the large fontanelle almost on a line with the small one; in other words, the head was not flexed. He continued pressure with his two fingers upon the sinciputal end, and after two pains only, he had the satisfaction of feeling the sinciput recede, and the occiput descend. Labor terminated in one-half hour.

In recapitulation, the author said that: 1, a proper diagnosis of position and presentation should be made early; 2, that occipito-posterior positions are frequent; that these positions result in a great fetal mortality and maternal morbidity; 3, that this position can be corrected and labor shortened.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Prescription Writing—Continued.

III. Nouns of the fourth declension, as previously stated, have the ending *us* and do not change in the genitive. Practically the only noun of the fourth declension in common use is "spiritus."

Referring again to our prescription, the directions to the druggist it will be noticed are written in the Latin. The word *misce* means, when translated, "mix thou." The word *fiat*—meaning "may be made"—is in the subjunctive mood, therefore, in the above, *mistura* is in the nominative case the subject of *fiat*. If a number of capsules were ordered instead of a mixture then *fiat* would have to be changed from the singular to the plural, as follows: *fiant capsulæ*, capsulæ being in the nominative case, plural, the subject of fiant.

The directions to the patient are of extreme importance, and this is where the physician should express himself concisely, clearly and positively. It should be stated how the medicine should be taken; that is, whether in water or otherwise, and whether the water should be hot or cold when the medicine is poured into it. For instance, we know that sulphonal, to produce the best results and promptly, should be dissolved in hot water, while if chloralamid is dissolved in hot water it is easily decomposed. It should also be stated definitely whether the drug should be given before meals or after meals on account of the liability of producing a gastritis, or whether it should be given at night or in the morning. We know that it usually takes from twelve to twenty hours for the lapactic pill to act and consequently it is better to give it upon retiring, while magnesium sulphate will produce much better effects if given upon rising in the morning with the patient in the upright position. We urge the physician to be positive with patients as to the promptness of taking the medicine. If it is a matter of indifference to the physician

it will soon be of greater indifference to the patient. In writing out the ingredients it is much better to write them in full and not abbreviate. In this way mistakes upon the part of the druggist will be obviated. While there can be no objections in abbreviating some of the terms, a few illustrations taken from Wilcox may serve to show how mistakes may arise:

Acid. hydroc. (may be Acidum hydrochloricum or Acidum hydrocyanicum).

Ext. col. (may be Extractum colchici or Extractum colocynthidis).

Hyd. chlor. (may be Hydrargyrum, Hydras, Hydrochloras or Hydrocyanicus).

Sulph. (may be Sulphur, Sulphid, Sulphate, or Sulphite).

In this connection it does not come amiss to mention the importance of writing plainly and legibly. More than one case is on record where suits have been instituted against druggists for improperly compounding a prescription, who in turn tries to shield himself behind the hieroglyphics of the physician. A physician of prominence in a large city, who writes an unusual number of prescriptions, has the reputation of writing so illegibly that only one druggist in the entire city dares to attempt to compound the prescription, and even he at times has to inform the patient that it will take some time to fill the prescription in order that he may quietly consult this physician concerning the ingredients involved.

Eczema.

When eczema is present dependent on digestive disturbances, with constipations, etc., present, Stelwagon in *Amer. Text-Book of Ther.*, recommends the following in conjunction with local applications:

℞.	Magnesii sulphatis	℥i	32
	Acidi sulphurici dil	3ii	8
	Ferri sulphatis	gr. vi	36
	Aq. menthæ pip. q. s. ad	℥vi	192

M. Sig.: One tablespoonful is to be taken in a glass of water one-half hour before breakfast and if necessary upon retiring at night.

In some cases he advises the addition of sulphur in proportion of drams 4 (16.) to the 6 ounces (192.) to the above mixture to increase its activity.

The following saline mixture is also of service for the same purpose:

℞.	Sodii sulph. gran	3x	40
	Sodii bicarb	3iv	16
	Sodii chloridi	3ii	8

M. Sig.: Keep well closed, take one or two teaspoonfuls dissolved in a glass of water one-half hour before breakfast.

He further states that many patients can not properly bear the salines and under such circumstances he advises the following as a stomachic laxative tonic:

℞.	Sodii salicylatis	3ii	8
	Ext. rhamni purshianæ flu	3iss	6
	Tinct. nucis vom	3iv	16
	Tinct. card. comp. q. s. ad	℥iii	96

M. Sig.: One teaspoonful to be taken after each meal in water.

For local medication to the skin, lotions, oils, ointments, paints or plasters may be used. He states that the most useful preparations are those containing zinc oxid, talc, boric acid and starch, combined sometimes with salicylic acid, carbolic acid or camphor. He recommends sometimes for such local application, the following:

℞.	Acidi salicylici	gr. ii-v	12-30
	Acidi borici	3ii	8
	Zinci oxidi		
	Talci veneti, āā	3iii	12

M. Sig.: Cleanse the parts well with water and apply locally once or twice a day.

The following is used as a lotion in the erythematous and papular varieties:

℞.	Acidi borici	3ii	8
	Acidi carbol	3ss-3i	2-4
	Glycerini	3ss	2
	Alcoholis	3ss	2
	Aquæ q. s. ad	Oss	256

M. Sig.: Apply locally twice a day.

Or:

℞.	Calaminæ		
	Zinci oxidi, āā	3iss-3ii	6-8
	Glycerini	3ss	2
	Alcoholis	3ss	2
	Liquoris calcis	℥ii	64
	Aquæ q. s. ad	Oss	256

M. Sig.: Apply locally.

If the itching is too troublesome, from one-half to one dram (2.-4) of carbolic acid may be added to the above or grains 2 to 8 (.13-.15) of thymol.

Treatment of Acute Rhinitis.

This is the time of year when a great many patients complain of inability to breathe through one or both sides of the nose or perhaps one side is closed only to become free when the other side becomes closed. In such cases the indications are to decrease the congestion and consequently the size of the turbinated bodies. In such cases the following is used a great deal internalls:

℞.	Quininæ sulphatis		
	Sodii salicylatis, āā	gr. iii-iv	20-25
	Camphoræ monobromatæ	gr. ss	03

M. Ft. capsula No. 1. Sig.: One such to be taken four or five times a day.

To soothe the inflamed Schneiderian membrane Mackenzie recommends the following in the form of an inhalation:

℞.	Tinct. opii camph	℥ss	16
	Tinct. benzoini co	℥i	32

M. Sig.: Put one teaspoonful to the pint of hot water and use as an inhalation three times a day.

The temperature should be raised to near the boiling point and the vapor inhaled for fifteen minutes at a time, six deep inspirations being made in each minute.

We might again state the efficiency of adrenalin to relieve the local congestion.

Treatment of Hemorrhoids by Zinc Chlorid.

The following is recommended by Julie, as noted in *Am. Medicine.* The parts should be thoroughly washed and an ointment of iodoform and vaselin applied to the hemorrhoidal mass; 15 minims of the following solution is then injected into the base of the mass:

℞.	Zinci chloridi	gr. viiss	5
	Cocainæ hydrochlor	gr. iii	20
	Aq. destil	3v	20

M. Sig.: Use as advised above.

He states that patients do not complain of the pain, but the next day a slight inflammatory nodule is produced which disappears on the fourth or sixth day. He does not believe that thromboses are liable to occur, especially if care is taken when making the injections to distribute the liquid.

Tracheo-bronchitis in Children.

The following is recommended by Markan, in *Med. Press and Circular*, in cases in which irritation and cough is proportionately greater than the inflammation:

℞.	Syr. aurantii (flores)		
	Syr. codeinæ, āā	℥i	32
	Tinct. aconiti	m. xii	75
	Aquæ	℥ii	64

M. Sig.: One teaspoonful daily for a child of three months. to be increased according to the age of the child.

Treatment of Acute Albuminuria After Scarlet Fever.

The following is recommended by Otto Maier, in the *Post-Graduate*:

℞.	Pilocarpinæ hydrochlor	gr. i	06
	Infusi digitalis	℥iii	96

M. Sig.: One teaspoonful every three hours.

He also recommends that a hot bath be given daily and a diet consisting of milk and ice cream. To promote elimination by the bowels give the following:

℞.	Hydrarg. chloridi mitis	gr. iiss	15
	Pulv. jalapæ	gr. ivss	28

M. Ft. chart. No. i. Sig.: One such to be taken twice a week.

Treatment of Acute Articular Rheumatism by Massage with Petroleum.

Sarafidis, as noted in *Amer. Medicine*, states that he has cured fifty cases of acute articular rheumatism by massage of the extremities with petroleum. Either crude petroleum or the ordinary oil may be used. Massage should be carried on in the direction of the venous circulation and practiced for ten minutes daily. If erythematous papules should appear, discontinue the treatment for a day or two. He claims to have perfected cures in five to seven days, and that by this method the temperature is lowered and the serous membranes thus protected from inflammation. No cardiac or visceral complications have been observed; the treatment can be carried on in the presence of an interstitial nephritis, under which circumstances sodium salicylate would be contra-indicated. The same holds true of its administration to pregnant women.

Medicolegal.

Three Hundred Dollars for Injury to Knee.—The Supreme Court of California holds, in the personal injury case of Sheyer vs. Lowell, that not only was an award of damages of $300 clearly not excessive, where the party suing was laid up with a badly injured knee and under the constant care of physicians for two months, and at the time of the trial, nearly a year later, had not entirely recovered, but that the evidence would have supported a verdict for damages greater than $300.

Medical Examiner a General Agent—Fraud of.—The Supreme Court of Tennessee says, in the case of Bennett vs. the Massachusetts Mutual Life Insurance Company, that it is true that the medical examiner of a life insurance company is not a general agent of the company in the broad sense of the term, but one whose duties are confined to a single feature or department of the business, but in that department he is a general agent. Then, it holds that the insured may maintain an action to have the contract of insurance rescinded, and to recover the premiums which he has paid, on the discovery that the answers made in the application are not true, and are not as made by him, but were fraudulently made by the examiner, where in case of the death of the insured the company would have a prima facie case for avoiding the policy for such false statements and it would be hard for others to show the fraud. In such a case, oral evidence, it holds, is competent to establish the fraud, and admissible to show that the contract as written is not the contract as made by the parties. It also suggests that, whatever may be the rights of third persons growing out of the matter, it will not lie in the mouth of the company upon the one hand to confess its fraud, and on the other to say that, "You are estopped to rely upon that fraud, because you have not more promptly discovered it."

Right to Have Hand Examined by Physicians.—In Louisville & Nashville Railroad Company vs. Simpson, where the Court of Appeals of Kentucky has reversed a judgment for damages against the company, the party who brought the action claimed that her hand had been injured in a collision, and that she was permanently crippled; that because of the injury she could not close two or more of the fingers of that hand by voluntary exercise of its muscles. No other permanent injury was claimed, nor was the injury to that member apparent to an ocular inspection. On the trial she showed the hand to the jury, demonstrating she claimed how far she could close the fingers by the use of their muscles. She declared that the leaders and joints of the fingers were stiff and enlarged. One of her witnesses (her physician) testified that he could not tell by an examination of the hand whether it was permanently injured or not; that he would have to rely upon the statement of the patient. She submitted her hand to his examination while he was testifying. Subsequently the company introduced two physicians as witnesses, who testified that they could tell by an examination of the hand, without reference to what the patient said, whether it was stiffened as claimed, and whether such injury was permanent. But she declined to permit the witnesses to examine her hand, and the trial judge overruled a motion to compel her to do so. The Court of Appeals holds that this was reversible error. It says that to permit the party suing to testify that the member was injured and that the injury was permanent, and to deny other competent witnesses, who were especially skilled in treating such injuries, an opportunity to examine the hand and to demonstrate, if they could, that it was not in fact injured at all, was an abuse of the discretion lodged with the trial judge.

Malpractice Liability for Negligence in Amputation.—The Court of Appeals of Kentucky says that it appeared, in Alexander vs. Menefee, that it was necessary to amputate some distance from the wrist the arm in question, the wrist having been broken by a discharge from a shotgun. The complaint, in substance, was that the physician who was employed to treat the arm performed the operation without the assistance of another surgeon or physician to aid in administering anesthetics, as a result of which the party suffered much during the operation, and did not remain quiet or unconscious, and thereby the operation was not performed as it should have been; that one of the arm bones was cut shorter than the other, which prevented healing of the wound, and rendered it impossible for the flesh to cover the bone in such a manner as to heal. Other defects and unskilful actions were alleged, the result of which, it was alleged, caused the arm to remain sore, and caused the bones to protrude through the skin and become entirely uncovered, and would cause the bones to decompose; that it would be necessary to have the arm resected, etc. The answer was a complete traverse of all the averments in the petition which showed a right to recover damages. The trial resulted in a verdict and judgment for $1500 damages against the physician, which the Court of Appeals of Kentucky affirms. It deems it unnecessary to recite the evidence introduced, and says that, as the jury had the witnesses before them, as well as an opportunity to view the condition of the arm, it is not, therefore, disposed to hold that the verdict of the jury was contrary to law, or not sustained by sufficient evidence. Nor is it inclined to the opinion that there was any error in refusing to permit the physician, who was a competent and skilful physician and surgeon, there being no claim that he was not such, while, instead, it was substantially alleged, or at least the action was prosecuted upon that idea, and the recovery was sought, not upon the ground of incompetency, but upon the ground of negligence. Furthermore, the court says that there was proof tending to show, and from which the jury was authorized to conclude, that the treatment was not such as a reasonably careful physician in that neighborhood ought to have given.

Liability for Injury to Pregnant Passenger.—The Court of Civil Appeals of Texas, in St. Louis Southwestern Railway Company of Texas vs. Ferguson, affirms a judgment for $1000 damages in favor of a husband for injuries alleged to have been negligently inflicted upon his wife by causing an engine or train to collide violently with the car in which she was seated as a passenger, in the making up of a train. At the time she was about six months advanced in pregnancy, and within a few days thereafter gave premature birth to twins. The trial judge instructed the jury that the railway company was not an insurer of the personal safety of the woman while she was a passenger on its train, but owed to her the duty to exercise that high degree of care for her reasonable personal safety which a very prudent person would use under the same circumstances about the same matter; and a failure of the company, if any, to exercise such degree of care, would be negligence. This the company contended was erroneous. As a correction, it asked that a special instruction be given to the effect that it was not intended by the general charge to require of the company to exercise any greater care with reference to this passenger than to any other person; that, there being no evidence to show that the company had notice that she was pregnant, it could not be required to exercise any greater care of her than of an ordinary passenger; and, therefore, that, if the jury found from the evidence that the company exercised the care required of railway companies, in making

up its train, it should find for the company. It was insisted that, without knowledge of the delicate condition of the woman, the degree of care imposed by law upon the railway company was that due to all persons in usual and ordinary physical condition, and not such as might have been due to one "in the light of attending circumstances." But while there was no evidence that the company's servants in charge of the train and cars in question at the time of the coupling complained of had knowledge of the peculiar condition of this passenger, the court nevertheless holds that the judge's charge must be sustained, and that his rejection of the special charge requested was correct. It holds that the judge gave the proper standard of care, and says that the degree of care so prescribed, in its judgment, must be exercised by the carrier of passengers in the light of an imputed, if not actual, knowledge that the aged, the infirm, and those in delicate condition may and do constantly travel on the passenger trains of the country. Humanity is heir to many ills and destructive conditions requiring notice and peculiar care, and those commonly and constantly engaged in their transportation for hire ought not to be heard to say in excuse for their negligence, "We were without notice of the fact."

AMERICAN.

1. **The Tetanus Outbreak in St. Louis.**—The recent cases of tetanus following the use of antitoxin in St. Louis are discussed by Abbott, who notices the puzzling questions connected with them, especially as regards the origin of the infection. It is not easy fully to understand how the poison was introduced into the antitoxin, though neither the oxygen in the serum nor the antiseptic can certainly be said to destroy the possibly existing spores. But admitting this, the question arises: Were these originally introduced in sufficient numbers to account for the accident, or did they lie dormant in the serum until its injection into the susceptible human being? If the serum contained the bacilli or spores in such numbers as to have produced the disease, it most certainly would have developed in some of the very susceptible animals employed for the standardization of the antitoxic strength of the serum, but this, we are told, did not occur. So far as evidence will permit, Abbott thinks that the facts point more to a toxic origin for the accident, though there are obstacles to the establishment of this hypothesis. The question arises whether it is possible for the horse to give a serum in the incipient stages of the disease on August 24, when it succumbed only in the early part of October. We do not know the length of the incubation period of tetanus and can not positively say that it might not be five weeks in horses, though this is not the case in man. It is possible, he thinks, for a very small quantity of undesirable toxin to be introduced into the serum which might multiply in it and he thinks that so far as tetanus is concerned, however, the detection in such products as antitoxic sera is a matter of comparative simplicity. After the St. Louis experience, he would not regard anyone justified in distributing serum, until all doubt in the matter had been cleared away. This can be done in several ways: by very careful observation of the horse under treatment, by the occasional prophylactic use of tetanus antitoxin on the animal, by keeping the serum for a reasonable length of time after it is prepared and before it is distributed, the horse being under observation and, finally, by a special test directed to this point in which there is injected into a highly susceptible animal not the fraction of a dose used on human subjects, but the full human dose. If, after this, the animal exhibits no signs of tetanus, one is justified in assuming that the serum is free from anything capable of causing the disease. When we consider the thousands of injections that are annually admin-

istered with this very rare undesirable result, we must regard the deplorable accident of St. Louis as an exceptional one, which could not have been foreseen and might fall to the lot of any of us.

2. **The Bottini Operation.**—The cases of prostatic hypertrophy may be divided, according to Horwitz, into three groups: 1. Those in which the enlargement does not produce obstruction nor inconvenient symptoms. 2. Where there is a constant residual urine associated with disturbance of the function of urination and the patient is obliged to employ the catheter, but nevertheless requires no other treatment and may live to old age in comparative comfort. 3. Those who sooner or later suffer from what is called "the breakdown in catheter life," the catheter being used with great difficulty and pain and grave secondary complications being the result of the reduction of their resisting power, and loss of sleep. He believes that prostatic hypertrophy begins in early age, but that the obstructive symptoms do not appear until later when the growth has attained a considerable size. He reviews the history of the operation for this condition and especially remarks on the Bottini operation, which he thinks is the most successful method, attended by the greatest number of systematic cures and with the least mortality, viz., 4.5 to 7 per cent. The objections that have been made to it by various writers that it is uncertain and dangerous to perform, that the operation is done in the dark, that relief is but temporary, etc., he thinks are contradicted by the experiences of numerous observers. He has had thirty-six cases under his care and there was a tendency to recurrence of the obstructive symptoms in but three instances, making a second operation necessary. In each of these cases there was marked improvement in the physical condition. He is inclined to think that in the three cases the incisions were not made of sufficient length at the time of the first operation. This, however, is not serious as the operation is easily repeated and it is far better to do too little than too much. In the three years that have elapsed since his first operation there have been no complications of any kind in any case. In one case where he had the opportunity to perform a suprapubic cystotomy in a patient who had submitted to the Bottini operation seven months before, he found that all the obstruction had been removed and that there was a deep furrow in the median line of the middle lobe. Other evidences of this sort are noticed.

3.—See abstract in The Journal of September 14, p. 714.

4. **Intracranial Neoplasms.**—Pearce argues for the neuronic theory in explanation of brain tumors and their symptoms and believes that some form of electric energy is the cause of the continuation of life processes after birth and that the neuron theory accords with this. His argument is rather elaborate and can not be given in detail.

5. **Neurasthenia.**—Roberts describes the symptoms, causes, pathology, diagnosis, prognosis and treatment of neurasthenia. He lays special stress upon the disuse of anything like morphin, which he thinks has sent many of these unfortunates to death.

8. **Fertilization.**—The history of our knowledge of fertilization is first noticed by Gies with details as to Loeb's investigation, and in conclusion he reports his own experiments with enzymes. The chief experimental results of the work are given as follows: 1. Extracts of the spermatozoa of the sea-urchin, which have been made by the ordinary methods for the preparation of enzyme solutions, do not possess any power of causing proliferation of the ripe ovum. 2. No evidence could be furnished of the existence of a zymogen in spermatozoa. 3. Extracts of fertilized eggs, in the earlier stages of development, were likewise entirely devoid of segmental activity. 4. Enzyme seems to be excluded from the catalytic substances which Loeb and others have thought may influence the initial divisions of the ovum after the introduction of the spermatozoön, although it is possible that the conditions of these and previous experiments were unfavorable to the manifestation of activity on the part of fecundative ferment. It seems more probable, however, that Loeb's theory of the influence of spermatic ions in fertilization affords the true explanation of the phenomena in question.

10. **Tendon Transference and Arthrodesis in Infantile Paralysis.**—Three cases are first noticed by Bradford which illustrate the three methods of treatment, viz., mechanical, muscle and tendon transference, and the stiffening of the joint in cases of infantile paralysis. In the severest cases where all the muscles are affected, operative surgery seems to be useless. The application of an apparatus with the aid of a cane seems to be the only resource. When, however, as is more common, some muscle function remains, an advantage can be gained by the employment of non-paralyzed muscles. The muscles frequently left which retain some power are the sartorius, the adductor group, and the hamstrings. The transference of the sartorius to the rectus is a measure usually employed without difficulty, the only obstacle being the abnormal position of the sartorius, which is often nearer the hamstring at its lower attachment. A curved incision at the lower end of the femoral will bring to light the attachment of this muscle, which should be entirely freed, brought up and transplanted into the firm sheath of the extensor cruris. When it is found to be weak, the outer hamstring or adductor can be detached and brought forward, and inserted into the fascia and extensor cruris. Where the adductor group is completely paralyzed, the problem is difficult. Whether the transference of the glutei can in any way be accomplished to supplement adductors is uncertain, but may be possible, as is also the shortening of the paralyzed adductors that they may act as a cord to check extreme abductation. In paralytic disabilities of the knee where all the muscles are paralyzed, making transference impossible, arthrodesis is to be resorted to only where no mechanical treatment is possible. In paralysis of the muscles controlling the action of the feet, the combined employment of arthrodesis and tendon transference is of great value. Where all the muscles are paralyzed in the front of the foot, the tendo Achillis can be split and a portion transferred and attached to the paralyzed peroneus tertius or to the tibialis anticus, or both. The procedure is not difficult and is performed by making an oblique incision on the outer side of the leg, securing the tendon of the tibialis anticus and the peroneus tertius above the anterior annular ligament, following them well up to the muscular origin of the leg. A portion of the tendo Achillis is cut off and passed obliquely forward and stitched to both the cut tendons. Where the gastrocnemius is paralyzed, several procedures have been recommended, such as the insertion of the tibialis posticus and one of the peronei, or the splicing of the tendo Achillis; the latter has not proved of as great value as the other. Success in this operation depends not only on care in the performance, but also on the quality of the strength of the muscles which can not always be readily determined before operation. The peculiar anatomical condition of the foot must be considered. Tendon transference is of value for the purpose of preventing the dropping of the front of the foot, or where the muscles have been weakened. Where either the extensor proprius pollicis, anterior tibial, of peroneus tertius are unparalyzed, they can be transferred to either side and in this way give power for raising the front of the foot. Much will depend on the strength of the muscle and the length of the foot. If any of the muscles of the toes remain unparalyzed, it is possible to utilize the extensor communis digitorum by uniting a paralyzed anterior tibial or peroneal muscle or muscular fascia to the extensor communis digitorum. In this way in many cases the dropping of the front of the foot may be prevented. In many of the older cases distortion develops from the adapted shortening of the soft tissue. Valgus and varus deformities are established and aggravated by the abnormal strain brought on various portions of the bone. Here simple tendon transference is not sufficient to prevent relapse after a correction, and arthrodesis of the mid-tarsal articulation is of special value. This operation is easy. An external incision is made and the articulation between the os calcis and the cuboid laid bare, the peroneal tendons being pulled aside. The cartilaginous surfaces of the os calcis and the cuboid are

removed with a chisel and if any abnormality in the shape of the bone has taken place, this can be removed, as the incision can be enlarged or another incision made on the inner side, and the scaphoid and astragalus ankylosed in the same way. This, with proper correction, does not interfere with the up-and-down motion of the foot, but does interfere with the twist which it is desired to prevent. In cases without muscular strength of any of the muscles of the leg, front or back, an ankylosis between the tibia and the astragalus can be performed, but the advantage of this over a proper appliance is not manifest and the operation hardly recommends itself for this reason. A partial operation to strengthen the ligaments on either side of the ankle by shortening relaxed ligaments is of advantage. The percentage of complete success from these different procedures in a large number of cases is yet to be accurately determined by further clinical investigation. Where these measures have been carried out, benefit is evident in suitable cases and it is desirable to call attention to the advantage of a combination of arthrodesis and tendon transference, i. e., to the employment of one or both with or without suitable apparatus in proper cases, and to emphasize the fact that the surgeon has, in the management of this disability difficult of treatment, an opportunity for the employment of surgical judgment, anatomical and physiological knowledge, and the exercise of trained skill with the expectation that in a large percentage of cases benefit will follow his properly directed efforts.

13. **X-Ray in Sarcoma.**—Beck's article is a fully illustrated report of a case of sarcoma of the leg treated by the *x*-ray, which he thinks shows decidedly the influence of the *x*-ray on this disease. He thinks the danger of dermatitis, which is one of the risks of the strong application required, should not be regarded as having great weight in malignant cases. The fear of using the strong current may be responsible for the failures.

14. **Devitalized Air Toxemia.**—In this conclusion of his paper Denison argues for the need of better air supply in the building up of resistance to tuberculosis. He thinks tuberculosis is mainly a result of a common predisposition and that the medical profession has been trying to put the cart before the horse and has assumed an accompaniment to be a prime cause. What we should do is to determine the per capita need of air in ventilation in order that predisposition to tuberculosis may be prevented. If we could have an invention of an automatic deficient ventilation-indicator built into the side of the room to announce by sound or visible index the degree of deficiency, and if set at liberal gauge for purity and freshness of air it would help to eliminate tuberculosis from the earth.

15. **The Lane Lectures.**—In this tenth lecture Morris continues the subject of eczema in its various varieties in infancy, puberty, adult age, menopause an senility. The trade eruptions, mycosis fungoides, which has the appearance of eczema but is really one of the most formidable diseases in dermatology, psoriasis, pityriasis rubra, are described and also malignant diseases of the skin generally, including the one just mentioned; among these latter he merely mentions the ordinary skin cancers and sarcomas. The last condition which he describes is acanthosis nigricans, another rare disorder at present incurable.

18. **Blood Stains.**—Wood's article gives the detail technique of the examinations of blood stains for medicolegal purposes, the guaiacum and hemin chemical tests and the sodium tungstate test, microscopic examination and the agglutination test.

21. **Infection.**—Eisendrath points out the special modes of infection, illustrating it by the surgical anatomy of the hand and showing how tendon sheaths are special localities for the spread of the infection, and also points out the channels in which the suppuration follows in other parts; the difference between streptococcal and staphylococcal infection, methods of treatment, necessity of free incision, etc. He summarizes in conclusion as follows: 1. Ample incisions to lay bare every portion of the infected area, and counter incisions to relieve the collateral edema. 2. General anesthesia and a bloodless method of operating whenever possible. 3. The disinfection of an infected wound with strong antiseptics, etc., is of little avail, and may do great harm. 4. Most dependence should be placed on free drainage and moist dressings, with the use of mild antiseptics. No powder should be used until granulation is well established. 5. Absolute rest and elevation of the infected area. 6. After-treatment by secondary suture and early active and passive motion. 7. General treatment: strychnin, whisky and attention to the excretory organs.

22. **Otitis Media.**—The continuation of Funke's article gives a list of over 60 cases examined, and offers the following conclusions based on personal observation and a study of the literature: 1. There is no specific organism of otitis media. 2. Acute otitis media is not invariably mono-microbic as is commonly held. There may be but one organism, but with it are frequently found various associated bacteria more or less influential in the outcome of the case. 3. The organisms commonly found, in the order of their frequency, are pneumococcus, streptococcus, pyogenic staphylococcus, and the bacillus of Friedlaender. He is strongly inclined to believe in a definite grippal otitis due to the influenzal bacillus, which, however, quickly becomes associated with other organisms. 4. Diphtheria bacillus is more commonly present than is usually believed, either as an original infecting agent associated with streptococcus or pneumococcus or as a secondary infection carried to the already infected ear. 5. It is reasonable to believe, as his observations show, that it persists over varying periods of time in the discharges and may constitute a center of danger, as in its prolonged persistence in nasal localities, etc. Its frequent association with the bacillus pseudo-diphtheriæ has the same significance here as elsewhere—a factor not as yet fully determined. 6. The streptococcal infections are more serious and persistent than pure pneumococcal infections, but both are usually supplanted by the staphylococci sooner or later. 7. There is a true pneumobacillary otitis usually acute and quickly converted into a mixed infection. Its gravity depends on the character of the secondary infection. 8. Chronic suppurative otitis media is practically always a sequence of the acute. 9. Like the acute it possesses no specific organism. 10. Unlike the acute it is practically always polymicrobic. 11. Its polymicrobic character may be evinced in any of three ways: (*a*) A mixed infection of pathogenic organisms; (*b*) one or more recognized pathogenic organisms (usually pyogenic staphylococci) with one or more bacteria usually regarded as saprophytes; (*c*) The usual pyogenic and pathogenic bacteria are absent, and the discharges are maintained throughout by the activity of the organisms that commonly lead a saprophytic existence. 12. While anaërobic organisms may play an important part in chronic suppurative otitis media, Funke's observations have not established their constant presence as maintained by Rist. 13. The fetor met in the cases here reported can be explained by the presence of bacillus pyogenes fetidus without anaërobic organisms. 14. All clinical and collated bacteriologic data indicate that otitic inflammations present different bacteriologic findings in different localities. According to Moos the otitis complications of the influenza epidemic of 1890 were due to the pneumococcus in Vienna (Weichselbaum), and to the streptococcus in Strasburg, in Griefswald and in Bonn (Ribbert). 15. The literature establishes the existence of a primary tubercular otitis, but all observers agree as to the impossibility of routine demonstration of the bacillus in the discharge. 16. For the demonstration of the tubercle bacillus in suspected cases, he would recommend the examination of tissue obtained by the curette.

23. **Vaccination.**—The questions raised as to the efficiency of the different forms of vaccine lymph, glycerinated tubes, points, etc., are noticed and reviewed by Good, who argues in favor of the value of the glycerinated lymph and suggests a government commission to investigate the subject offering the following points as desirable for solution: 1. Does one attack

of smallpox give absolute immunity? If not, for what time is immunity accorded? 2. How soon after an attack of smallpox can vaccine vesicles be produced by careful vaccination with a good virus? 3. Should a person be considered not immune if, having had an efficient vaccination some few years before, a revaccination produces vaccinal possibilities? 4. The importance of carrying out control tests with one species of virus from four to six weeks after the original vaccine had apparently taken. 5. What kind of lymph is it most safe to rely upon, and what is the most approved technic?

27.—See also title 15, above.

28. **Migraine.**—Thomson's article is largely an argument for the autotoxic origin of migraine, more especially intestinal auto-intoxication. He says migraine is one of the penalties exacted for neglect of the means provided by Nature to assist the portal circulation and keep it free and active. The treatment which he recommends is largely dietetic and antiseptic, with special attention, of course, to elimination, etc.

29. **Ophthalmic Science and Art.**—Roosa's article is a review of the progress of ophthalmic science and art. He points out the importance of the ophthalmoscope as modified by Loring, the use of the ophthalmometer as left by Javal, advances in the treatment of trachoma, and myopia, the questions of strabismus in which the progress, he thinks, has been comparatively slow, and the satisfactory progress in the treatment of cataract and glaucoma.

30. **Private Charitable Institutions.**—The object of Stoddard's article, as he states, is to call the attention of the profession to the responsibility of medical officers in formulating and establishing well adjusted systems of education and training in institutions which have the care of the youth and adolescent and to the cultivation of the vast field of observation which, under systematic and combined effort, is capable of yielding a most valuable harvest of knowledge.

32. **Gastric Acids.**—The existence of hyperchlorhydria is doubted by Knapp, who offers the term organacidia gastrica as a substitute, the designation of the condition of the stomach due to the presence of large quantities of organic acids. He points out the importance, as it appears to him, of the search for butyric and acetic acid, and the value of a discovery which he has made as to the effect of butyric acid and monocalcium phosphate upon congo paper and upon dimethylamidoazobenzol. He describes his test for butyric and acetic acid, for the details of which the reader is referred to the original. The symptoms of organacidia gastrica, which he proposes to describe in a future article, are, he thinks, due to the presence of volatile organic acids, and the symptoms of hyperacidity are due to the presence of acid combinations together with volatile media, such as alcohol, aldehyde and acetone.

32. **Carbolic Acid Gangrene.**—After reporting a case, Sheldon discusses the condition and asks why it should occur in one case and not another, which he thinks is hard to explain. Levi's explanation for the fact that it more often follows dilute solutions than strong ones because of the failure to produce eschar is not, he thinks, satisfactory.

36. **Heroin.**—Ten cases of the employment of heroin, mostly cases of bronchitis, tuberculosis and Bright's disease, are reported by Wood, who finds that it has its decided advantages in chronic coughs and in no cases has he noticed any tendency to the formation of the heroin habit.

38. **The Railway Surgeon.**—Bishop gives the opinions of a lawyer as regards the duties of the railway surgeon, calling attention to their ethical side, especially in regard to the holding of communications sacred. The surgeon sent to see a patient and doing nothing more than simply examining and reporting on his case has no right whatever to use for the benefit of the railway company anything he may learn in treating the case or that may be communicated to him as a physician as regards the patient's history previously, etc., or anything other than the actual condition for which he examined him. He also advises the railway surgeon to absolutely ignore on the witness stand that he is employed by either party in the case.

39. **Tuberculosis Legislation.**—Glasgow protests against the proposed legislation in regard to tuberculosis in St. Louis requiring the disinfection of every case lasting over ninety days. He maintains that this measure would produce hardship, add greatly to the expenses of the patient or the city, and says that tuberculosis is not contagious in the ordinary sense of the word. If the health department is looking for contagious diseases to report, there is a class of contagious diseases, admitted by all to be contagious, which causes more misery and ill-health than consumption. Let it cause these to be reported and then regulate them. Fumigation such as is proposed moreover would be annoying and harmful to many suffering from tuberculosis and would cause more deaths than it would save lives.

42. **Medical Registration in Michigan.**—Harison gives an interesting history of the work of the Michigan Board of Registration, showing the thoroughness with which the law has been executed, and the economy of management, and gives his correspondence with a district attorney who does not consider the clause in the law stating that it shall be "the duty of the prosecuting attorney to prosecute violation of the law on information furnished by the records of the county clerk," as mandatory.

47. **Preputial Divulsion.**—Enright argues against the practice of circumcision for overgrown prepuce and favors the use of divulsion in all cases where there is not too great redundancy. He says, where the prepuce is narrow, divulse it, especially in children where the absence of a diseased condition is the rule.

50. **Genital Tuberculosis.**—After reporting and discussing a case, with an analysis of the literature, Young sums up the operative indications as follows: Epididymectomy with high resection of the vas deferens is the operation of choice. Castration should be confined to cases where the testicle proper is involved or the scrotal disease is extensive. Double castration, if possible, should be avoided, a portion at least of one testicle being left, even at the risk of local recurrence. Operations upon the seminal vesicles and prostate need be done only after the removal of the testicular foci has failed to arrest the progress of the disease in these organs, and it has spread to the bladder. Serious involvements of distant parts, pulmonary, urinary, osseous, etc., do not contra-indicate operation, especially since the more exact methods of using cocain have made general anesthesia unnecessary. The remarkable disappearance of extensive tuberculosis of the prostate seminal vesicles, bladder, kidneys, lungs, etc., that may follow removal of the testicle seems abundantly proven.

51. **Cervical Ribs.**—The case reported by Kammerer occurred in a woman aged 35, and apparently began in the left supra-clavicular region, producing pain and weakness in the arm which ceased for a time but afterwards returned. The *x*-ray revealed a cervical rib on that side with no evidence whatever of anything of the kind on the other side. The operation performed was the removal of a large portion of the bone and was followed by gradual improvement and almost complete recovery. He remarks in regard to the technique that no mention is made in the literature of difficulties, but he finds the operation is either very easy or rather difficult. In his case there was considerable embarrassment from the close proximity of important organs, arteries, etc.

54. **Acute Intestinal Obstruction.**—Three cases are reported by Hotchkiss following appendicitis and successfully operated on. He thinks that these indicate the great value of certain procedures under certain conditions. 1. The great utility as well as necessity of the free use of decinormal salt solution injections either subcutaneous or into the veins or rectum, both during and after the operation as a preventative of shock. In two or his cases the depression was so extreme that he thinks the patient could not have survived without this measure. 2. The great value of free incision into the over-

distended coils of gut; (*a*) in order to relieve upward pressure upon the diaphragm, and the disturbance of respiration and circulation dependent upon it; (*b*) to relieve the congested intestinal vessels and diminish the size of the enormously distended coils so that they may be handled without injury, the obstruction more easily dealt with and located, as well as to drain away from the interior of the gut a great quantity of stagnant fluid before it can reach the absorbing surfaces of the intestine below the obstruction. 3. The practicability and desirability of closing the abdominal wound without attempting to drain the peritoneum, and the leaving within the cavity sufficient saline solution to float the intestines and assist, perhaps, in their rearrangement. Measures which are essential in post-operative treatment are: 1. The persistent and intelligent use of the stomach tube with lavage. 2. The early and if necessary repeated administration of saline purges in concentrated solution and introduced through the stomach tube if they can be retained in no other way. 3. The use of the rectal tube for the relief of gas and the patient and persistent use of high enemata. These three measures patiently and intelligently employed with absolute abstention from morphin are the tripod on which rational and effective treatment is based, and on the intelligent use of which the life of the patient often absolutely depends.

56.—See abstract in THE JOURNAL, xxxvi, p. 711.

60.—Ibid, November 16, p. 1338.

61. **Complete Uterine Prolapse.**—Wiggin describes this condition as a reducible hernia through the pelvic floor, the sac being formed by the inverted vagina, containing besides the uterus, tubes and ovaries, a large portion of the small intestine, the bladder and rectum. It is caused by separation of the tendons of the muscles forming the pelvic floor where these unite in the median line, occurring usually during parturition. The malposition of the bowel is more or less increased by lifting heavy weights and by defecation, and perhaps is hastened by added weight of the small intestines which find their way to the lowest point. The complete form of this does not, as a rule, appear until late in life, but it causes much discomfort for many years before and the unsatisfactory permanent results of the various operations are due largely to the failure in recognizing the fact that the vaginal wall is practically a hernial sac with other contents than the uterus and appendages, and that consequently simple repair of the external perineal body, and the removal of a larger or smaller portion of the vaginal walls of the uterus itself would not correct the greatest trouble, malposition of the small intestines. The treatment requires, according to him, an operation to obliterate the hernial sac in the inverted and stretched vaginal wall and a restoration of the damaged perineal structures to their normal position as nearly as possible. His method is as follows: The patient is placed on a bed the end of which is raised six inches. Tampons moistened with glycozone are put in position. The parts are treated until all ulcerations are healed, the general condition being carefully looked after. A laparatomy is then performed in the Trendelenburg position to aid in drawing the bowels out of the way. They are usually found more or less attached to the peritoneal lining of the vaginal wall by adhesions which must be broken up. The uterus, which is usually small, is found and pulled upward by bullet forceps, thus drawing upward also the attached vaginal wall. When this has been accomplished a needle armed with kangaroo tendon is passed through the fibers of the uterus about the point of attachment to the round ligament, and is carried up and down the broad ligament in the form of a purse-string suture, the needle being finally made to emerge at the point of entrance, so that when the two ends of the sutures are drawn upon, the broad ligament on that side is forced up and drawn together so that the excessive length is done away with, and the uterus has a new point of attachment near the insertion of this ligament to the pelvic brim. The same process is repeated on the opposite side, the abdomen is flushed with saline solution, a quantity of which is left in, and the abdominal wound closed rapidly in the usual manner. The patient is again placed in a bed the foot of which is slightly raised, and after the wound has healed and the patient fully recovered, four or five weeks later, a new operation is performed to bring together the separated tendons of the perineal muscles with submucous sutures of catgut or kangaroo tendon. It will be found that at the time of the second operation, after the first one has been properly performed, that the redundant vaginal walls have practically disappeared. He has performed this a number of times in aged women and found it well borne, as it can be quickly done and involves no serious hemorrhage. Two cases are reported illustrating the results. He thinks spinal cocainization will perhaps be found particularly suited to this class of cases.

See also THE JOURNAL of November 16, p. 1338.

62.—See abstract in THE JOURNAL of November 9, p. 1266.

63.—Ibid. November 16, p. 1338.

64. **Concomitant Strabismus.**—Hubbell explains strabismus as primarily an abnormal condition of the oculo-motor nerve centers. There is no such thing as a muscle-shortening or elongation at its outset. Such conditions are the result, not the cause, of strabismus. By keeping this point in mind that it is primarily an abnormality of innervation—a vice of the controlling nerve centers—we should be saved from many errors of treatment.

65.—See abstract in THE JOURNAL of November 9, p. 1266.

66. **Milk Sugar.**—Jacobi's article is largely polemic, defending his recommendation of cane sugar in infant feeding against the criticisms of Huebner. He points out that the amount of milk-sugar in human milk varies at given periods and in different persons, and that laboratory combination tests of the theoretic preparation are not reliable. There are dangers of inordinate feeding with milk-sugar producing an excess of lactic acid. Among other things rickets has been thus explained by its chemical action.

67. **Adenoma of Both Adrenals in the Newborn.**—The interesting features of this case are summed up by the author as follows: 1. The presence of adenomatous hyperplasia in both adrenals, probably also in the left adrenal of Marchand, associated with retrograde changes in the right adrenal of Marchand, would suggest a congenital anomaly or defect in the development of the adrenal *anlage* from the Wolffian body. (The three-lobed left lung is also evidence of anomalous development.) 2. Suppression of the urine and death from uremia caused by toxic acute parenchymatous degeneration of the kidneys in this case. He describes the diagnosis of adrenal hemorrhage from adenoma and gives the following characteristics of the latter: 1. Absence of evidence of hemorrhage in or about the capsule. 2. The presence of a narrowing peripheral zone of apparently normal cortical tissue, beneath which there is usually a deep brown line separating the living and necrotic tissues. 3. The central portion composed of reddish-brown necrotic tissue without signs of extravasation or organization and showing on microscopic examination the remains of dead cells with blood-pigment in the capillaries between the cells.

72.—See abstract in THE JOURNAL of November 16, p. 1342.

74.—Ibid., p. 1341.

84. **Modern Methods in Country Practice.**—The elaborate paraphernalia recommended for diagnosis, etc., are remarked upon by Tonkin, who says that the country physician should be able to make all the more ordinary microscopic and chemical examinations of the blood, urine, pus and stomach contents. Any ordinarily intelligent patient can understand why the country physician could not make skiagraphs of fractures or thorough ophthalmoscopic examinations, but he would not understand the necessity of sending sputa, blood, or pus away for examination. The microscope is a necessary part of the physician's outfit and for sputum examination no other apparatus is necessary. Blood examinations are unnecessarily neglected. We do not require an exact count of the red and white cells. Any extensive leucocytosis may be at once detected by examining a thin film of blood under the ordinary

cover glass. Pernicious anemia is characterized by the striking variations in the size of the red cells and the presence of nucleated red cells of extensive size and by the tendency of all the colored cells to stain dark brown with eosin. Chorosis is differentiated by the red cells taking the red stain only slightly. The Hammerschlag's specific gravity method should be enough to estimate the hemoglobin and he gives the figures and the method. A chemical analysis of the stomach contents may not be required, but ordinarily the test meal can be used by the ordinary country doctor. He also describes a contrivance for intracellular infusion of saline solution which is easily devised, consisting of a pint or quart bottle with a two-holed rubber cork, one carrying a small glass funnel, the other a glass tube at right angles with the cork to which is fastened three or four feet of rubber tubing with a slim aspirating needle. Place some sterilized absorbent cotton in the mouth of the funnel to act as a filter, leaving the cork loose enough to permit of escape of air. When the bottle is full, fit the cork down tightly and pour the solution into the funnel until it runs from the needle, allowing it to run until the funnel is empty when the apparatus is ready for use. The saline solution can easily be made by putting 50 grains of pure salt to the pint of water. The rate of infusion should not exceed one ounce per minute for a patient weighing 135 pounds.

87. **Gastric Hyperacidity.**—This term, which is confused sometimes with hyperchlorhydria, implies simply an excess of acids whether due to total HCl., free HCl., acid salts or fermentation acids. Hyperchlorhydria is of more limited signification, implying a definite group of symptoms brought about only by an excess of free hydrochloric acid. Cowie has experimented on the stomach analyses of a large number of patients with different forms of insanity and offers evidences in favor of the neurosis theory and the theory of anatomical changes in the gastric mucosa. He reviews the relation of starch digestion to hyperchlorhydria, its frequency, which he finds much less than that of hyperacidity, its symptomatology and diagnosis. He thinks in all cases showing hyperchlorhydria it is of importance to recognize whether it is a functional neurosis or whether it is due to anatomic changes. In the absence of tissue bits we remain in uncertainty unless clinical symptoms point directly to a so-called nervous basis.

106. **The Arid and Semitropic Southwest.**—Betts' article is a description of the climatic features of Southern Utah, Arizona, and Southern California as compared with other western localities like Denver and Salt Lake City. He finds that there are many advantages in Salt Lake climate with its absence of extremes, and also in Southern Utah and portions of Arizona, which are not yet fully utilized by health seekers and physicians. He thinks the ideal climate for consumption is one which will stimulate the greatest possible outdoor life. Hence a mild, dry climate of moderate altitude, with a high percentage of sunshine, low wind rate and comparatively free from sources of tuberculous infection, best meets the requirements.

107.—See abstract in THE JOURNAL of July 13, p. 137.

114. **Somnambulism.**—The theory brought out here by Gasser is that there is a circulation in the nervous system of some sort which he thinks gives the only comprehensive interpretation of the facts of the functions of the organism in the various conditions of consciousness, etc.

115. **Unjust Food Laws.**—Randall argues for the use of formaldehyde in food preservation and disinfection, and thinks that the prohibition of its use may do more harm than good. He thinks that it is the one agent that will solve the harmless sterilization of milk, and quotes Foulerton in support of his view.

122. **Smallpox.**—Chapman, from his analysis of the facts, thinks that the three causes now operating over the country most likely causing the continuance of the present epidemic of smallpox are the following: 1. Mistaken or tardy diagnosis. 2. Failure to enforce quarantine. 3. Inattention to vaccination, either in the insertion of the virus or the lack of observation of the patient afterward.

127. **Postpartum Hemorrhage.**—After reporting several cases in his own experience, Jump says they have taught him in connection with what he has learned of the experience of others: 1. That there should always be plenty of hot water ready for use in case the delivery should require it. It is a good plan to add a little turpentine to the hot water when using it to control uterine hemorrhage. 2. Never again to administer quinin or any other drug for the purpose of hastening labor. He finds there are other physicians besides himself who consider quinin as the possible cause of postpartum hemorrhage. Another thing he never insists on is the patient's remaining in bed, nor does he care what position she gets into until it is time for the head to be delivered, and he makes as few examinations as possible. He finds that in slow labors if the patients will kneel on the floor and lay their heads upon the bed for a few minutes this position tends to relieve the parts and to induce strong pains. If he finds labor so tedious as to endanger the life of the baby or the health of the mother, he gives an anesthetic and uses forceps. 3. As a prophylaxis immediately on the termination of the second stage, he administers a teaspoonful of a mixture of one part of tincture of capsicum and ten parts fluid extract of ergot. This seems to produce a permanent contraction quicker than does ergot alone.

129.—See also title 142.

132. **Syphilis Insontium.**—Shelmire believes that syphilis contracted innocently is more common and important than is usually supposed, and reports several cases, all but one in physicians, in which it was thus acquired.

133. **Drug Habits.**—Lott recommends an apparently rather heroic method of treatment in morphinism by hydrobromate of hyoscin. He gives 1/100 of a grain and follows it by 1/200 of a grain from thirty minutes to an hour for from twenty-four to forty-eight hours, until the patient has taken from 40 to 60 doses, sometimes decreasing or omitting a dose, closely watching the pulse and respiration. The object is to secure hyoscin intoxication. When that is reached, as is shown by the restlessness, dilated pupils, dry throat, hallucinations, etc., he gives only enough to keep it up for from twenty-four to forty-eight hours. The patient is allowed water freely and is closely watched by the nurse, and if necessary a little dose of morphin may be given or strychnin, nitroglycerin or digitalis for the heart. At the end of the first stage of treatment the patient comes out from under the drug and no longer craves his usual dose, and then he begins the second stage with pilocarpin in 1/8 gr. doses, repeated every hour until its physiologic effect is secured. Then the time is lengthened between the doses, but they are kept up long enough to eliminate the drugs that have been stored in the body; in other words, until the last vestige of hyoscin symptoms has disappeared. There will be likely to be some diarrhea and pain in the knees, elbows, etc., and sometimes cramps. For these he gives subgallate of bismuth for the diarrhea and sometimes bromids or similar sedatives. Then under the stimulation of wholesome nutritious food at the end of a week, the patient begins to reach the normal condition.

142.—See also title 129, above.

143. **Heredity and Acquired Characters.**—Kime believes in the heredity of acquired characters and offers the following as a plausible, practical and consistent statement: "Acquired individual, permanent characteristics, produced through natural or perverted functions of the body become hereditary in character. The earlier in life such characteristics are acquired, the greater the tendency to transmission, and when carried through successive generations, tend to become permanent hereditary characteristics." He refers to various evidences in favor of this view, among them those of Talbot and Wolff on Jews, and as deductions from the above upholds the right of the State to interfere with whatever customs, etc., may lead to defective heredity. It is our duty to have proper legislation and registration to prevent the propagation of criminals, insane, inebriates and disease.

145. **Continued Malarial Fever.**—Under this name Howell describes a fever which may occur with or without chills, and

is slightly remittent in character, the pulse following the temperature and proving a valuable guide. If it does not come down with the temperature, it indicates that the disease is not progressing favorably. In rare instances the disorder may have a sudden onset. The tongue is atypical, the edges are red and the border has a light colored coat; the center is covered with a brown coating, and strawberry spots show on the white border. In the latter part of the disease the tongue becomes dry and cracks, and there is anorexia, constipation, scanty urine from the beginning with some albumin as the disease progresses, some headache and backache are present, not the photophobia or hebetude of typhoid. Physical examination shows an enlarged liver and hypertrophied spleen. After the seventh day there is usually tympanites throughout the abdominal cavity, but no rose spots are present. His treatment has been largely the use of calomel in the beginning with magnesium sulphate, giving quinin for four or five days and reducing it gradually or discontinuing it at the end of that period. When the quinin has been stopped, and sometimes before, he begins with a 4-ounce mixture composed of one-half ounce of dilute nitro-muriatic acid, and three and one-half ounces of elixir of lactopeptin, and gives one teaspoonful every four hours while the patient is awake, so long as the bowels are not too much irritated by it. He controls the fever with phenacetin in small doses and cold water. He uses a careful diet and specially recommends buttermilk and beef tea made with Mosquera's beef jelly. He does not express a positive opinion as to the nature of the disease.

FOREIGN.

British Medical Journal, November 9.

Prognosis in Relation to Disease of the Nervous System. Judson S. Bury.—Bury reviews some of the elements which he thinks essential factors in the determining of prognosis: 1. As regards the attacking agent, our knowledge of the various agents is too limited to help us much; a few points in the nervous system seem to be fairly certain; there is good evidence that irritation of the sensory nerve may lead to muscular atrophy, the absence of thyroid secretion seems to be the cause of impaired brain function in myxedema. We are daily acquiring more knowledge in regard to poisons producing nervous diseases such as alcohol, lead, arsenic, and those produced in the body. By analogy we reason the existence of action of other toxins. Two striking features may be noted, viz., the selective action of poisons and the immunity which is sometimes the direct result of that action. Syphilis is especially noted as regards both these points and it is remarked that since we have to speak with great caution about the course of disease or its production by this toxin of which we know so much, hence there is need of greater care in speaking of the action of poisons whose effects are known so little as those which we assume to be the exciting agents of such disorders as multiple sclerosis, Landry's paralysis and many other conditions. The prognosis in relation to the morbid anatomy is next considered. The mere size of the lesion appears to often have very little effect on the prognosis of the disease. Portions of the brain may be extensively damaged while other parts like the medulla afford very little space for any abnormal growths or disease without serious involvement. Lugaro claims that some parts of the nerve cells are more seriously involved than others, and that the lesion of chromatic substance is reparable while those of the other parts of the cell are less so, but Bury considers this statement in its fuliest application somewhat doubtful. The nature of the lesion is also hard to determine and he is inclined to believe that each poison has its own point of attack and that the earliest change in each disease has its own peculiarities unknown to us at present, but which if visible and thoroughly recognized would enable us to diagnose the condition and foretell its developments. The only manifestations of disease are symptoms, and how they are to be interpreted is a question; the difficulties are increased by the fact of idiosyncrasy. The sudden changes that may occur in serious nervous diseases like the brightening up, for instance, in tubercular meningitis which has been observed, and the temporary improvement from direct irritation in insanity are mentioned. The necessity for care in the forming of judgment is emphasized. He says it is difficult to understand how the ups and downs which are such marked features in the clinical history of chronic nervous disease can be explained on the hypothesis of primary progressive degeneration of neurons owing to exhaustion of their specific vital energy, and apart from the direct action of toxins circulating in the blood. Assuming that the poison is the most common exciting cause of nervous disorders, prognosis will vary with knowledge of the proper treatment for its elimination. In most cases we know neither the nature of the poison nor the method in which it is introduced into the circulation and treatment is purely empirical and often fails. We employ massage, baths, purgatives, alteratives, and place the patient under the best hygiene conditions and yet often without producing any immediate results. We need also remedies for counteracting the effects of poisons, and here we must hope for fresh discoveries regarding the effects of glandular extracts and the nature of toxins and their antitoxins. The influence of one disease upon another is worthy of renewed investigation; also further studies are necessary to establish the influence of one part of the nervous system on another, the value, for instance, of the sensory impulse in maintaining a proper nutrition of motor neurons as affording an explanation of the beneficial effects of massage, passive movements, and galvanism. Proof of this and other facts which may be derived from a study of the pathology and history of symptoms give us hope for the future and suggest that further study, clinical, pathological and chemical, will do much to improve the prognosis of many nervous disorders.

Local Treatment in Diseases of the Upper Air-Passages. Sir Felix Semon.—In this second lecture Semon takes up the local manifestations of general systemic diseases, particularly tuberculosis, and thinks that we should avoid as much as possible the word "cure" when speaking of the chances of treatment. In systemic disease the process is not purely local and though we relieve the manifestation we can not promise that the arrest will be a permanent one. Secondly, in no case is there greater need of individualization in treating disease on its own merits than in laryngeal tuberculosis, and the situation and extent of the local disorder will have to be carefully considered. If there is only infiltration without broken surface, he advises to leave matters alone. If there is ulceration the question of its situation and extent are of paramount importance and the local treatment will have to vary according to the amount of ulceration and its effects on diseased portions of the larynx. Sometimes energetic treatment will yield gratifying results in single ulcers, but no general rule can be laid down. In ulcers of the epiglottis, mucous membrane over the arytenoid cartilages and elsewhere, the difficulties are greater and treatment less satisfactory. Local treatment is legitimate and if intralaryngeal measures fail and dysphagia be excessive, or a subglottic ulceration spread to the posterior wall of the larynx, external operation may be considered. But the external wound in these cases is apt to become infected and a second extensive operation become necessary. Where the whole or nearly the whole of the mucous membrane of the larynx is one mass of ulceration with perichondritis and chondritis or caries, palliative measures alone are suitable and nothing has given him so much satisfaction as the insufflation of orthoform. The patient's general health and pulmonary condition are also to be taken into consideration. If local treatment is determined on it must be efficiently carried out. In syphilis of the larynx he has for a long time ceased to include local treatment as the routine measure in his methods. That means he does not exclude it, but would not make daily applications in addition to constitutional treatment, which last he relies upon. In affections of the upper air-passages due to disease of the central nervous system, he adheres to the use of electricity, especially in functional aphonia, and he also advocates prophylactic tracheotomy. In cases of bilateral well-developed paralysis of the abductors where suitable treatment fails in widening

of the glottic space, he would fully explain the situation to the medical adviser or the patient himself and his family and let them share the responsibility of the operation. In local manifestations depending upon local disease of the correlated areas Semon refers at length to the influence nowadays believed to be exercised by the state of the nose on inflammatory disease of the larynx and pharynx. While admitting this to a certain extent he thinks it is overestimated and the worst of it is that the theory is carried into practice, and useless nasal operations performed. In affections of the upper air-passages supposed to exert an influence on the other organs of the body, he says that the original sound principle has been hounded to death by being exaggerated. There is no doubt that there is a certain amount of influence, but the so-called nasal inadequacy has not the importance that is claimed for it. It is perfectly unintelligible to him how a slight degree of obstruction in the nose proper, especially on one side, can have such a distressing effect upon the middle ear which he has often seen ascribed to it. Unless the Eustachian tube is involved he sees but little possibility of ear trouble. He looks upon the endeavor to improve the labyrinth disease by removing a crest from the nasal septum with feeling much akin to those which animate him when he sees primary inflammations of the larynx treated by way of the nose. Nasal reflex neuroses are, he thinks, the most unsatisfactory subjects in modern medicine. The idea of the late Professor Hack has been exaggerated and carried to extremes by his followers. All that we can say is that in a number of cases physiologic reflexes are produced from the nose just as a reflex cough is sometimes produced from the external auditory meatus. The typical affection of nasal reflexes of the neuroses is hay fever, and the treatment of pathologic conditions of the nasal mucous membranes in many cases relieves it. Similarly, genuine bronchial asthmas are complicated by nasal polypi or may be relieved by removal of the latter. Hack's doctrine could never have obtained the popularity it has if there had not been something in it, but the mistake which his enthusiasm led him to make, has been exaggerated by his adherents and this is still being done. He tabulates the experience of various observers as to asthma and nasal irritations, and criticises severely Dr. Dundas Grant's views. The local symptoms and symptoms of obscure origin are noticed. The morbid readiness to discover disease, this desperate effort to find in every case and at any price a local explanation which has been in the ascendant of late years is, he believes, unsound, retrogressive, and greatly to be deprecated. We must keep in mind the necessity of proper proportion being observed between the gravity of the disease and that of the interference; the latter part of his article is a protest against the views and practices of certain authors.

Some Symptoms Produced by Tumors of the Optic Thalamus. J. MITCHELL CLARKE.—Clarke reports a case of brain tumor associated with marked intention tremor in the left arm and to a less degree in the leg, and involving the right optic thalamus, extending backwards and downwards into the subthalamic region, where it invaded the opposite side and pressed on the right internal capsule and the crura cerebri. It also involved the subthalamic region, red nucleus, aqueduct of Sylvius, and flattened and displaced the quadrigemina. Section showed degenerated tracts from the right hemisphere and well-marked and definite degeneration in the left cerebellar peduncle, which was not present on the right side. He thinks that the tremor especially occurring with tumors in the optic thalamus and those of the corpora quadrigemina and to a less degree the cerebellum, the balance of evidence is in favor of their being due to implication of the superior cerebellar peduncle, the course of events being that the tumor first affects the peduncle and later in the course of growth presses upon and more or less destroys the pyramidal tract in the internal capsule, crus or pons, and that thus the tremor appears first, but later disappears owing to the occurrence of more complete paralysis and of spastic contraction. Further investigation is required as to the implication of what special fibers of the superior cerebellar peduncle and tremor is due.

The Lancet, November 9.

The Personal Factor in Tuberculosis. DYCE DUCKWORTH.—The principal point in Duckworth's article is the identity of scrofula with tubercle and the individual predisposition of the patient. He maintains that we should pay due regard to the personal factor in tuberculosis and if we do this we will probably do more to avert the disorder from humanity than by any other course. Our modern pathologists discredit this too much and lay too much importance to the parasite itself. He also protests against too free estimation of cures in tuberculosis. The local disorder simply becomes quiescent and there may be recrudescence and relapse at any period during the patient's lifetime.

Freezing-Point of Blood and Secretions as an Aid to Prognosis. ALEXANDER OGSTON.—Ogston reports a number of cases in which cryoscopy was applied for diagnostic purposes and which, in his opinion, showed the value of the method. He thinks the high freezing point is probably a symptom of disease and the lower freezing point in some of his cases are purely owing to hepatic renal disease. It is his opinion that one of the most important fields of cryoscopy would be its power of indicating otherwise undetectable disease of the liver, at least in the practice of the operating surgeon.

The Sanatorium in the Treatment of Phthisis. T. CLIFFORD ALLBUTT.—The sanatorium treatment of tuberculosis is discussed by the writer, who sums up the chief questions he propounds in the following: "1. Can mixed infections be recognized from fever curves? 2. Can we distinguish between economical (*wirtschaftliche*) healing and complete (*wissenschaftliche*) healing? If so, what is the mean term of residence for the economical healing of early cases? How long in certain active cases, say from 6 to 8 per cent., is a febrile patient to be kept to bed in the reasonable hope of recovery? For instance, in a public sanatorium are we justified in retaining patients who have been confined to bed for six months, five months, or even for four months? 4. What estimates of improvement and what rules of prognosis can be based upon physical signs alone? 5. Is multiple tuberculosis, for instance, in lung and testicle too hopeless a condition for a public sanatorium? How far is it comparable with an equal extent of mischief in one organ? 6. Of what use, if any, is massage? 7. Of what use, if any, is hydrotherapy? 8. Are special pulmonary exercises appropriate at certain stages of progress; and if so, when, and under what conditions? 9. Must we repair the body at the expense of the life of the mind? Can we not give even some educational value to the sanatorium besides the medical drill of it?"

Archives Generales de Med. (Paris), August.

Pseudo-Neuralgic Variety of Rheumatic Spondylosis. H. FORESTIER.—There are three varieties of spondylosis, the ankylosing, simple and pseudo-neuralgic. The spine is more or less rigid in all three, but in the latter variety the patient stands erect, while there is marked stooping in the others. The pseudo-neuralgic pains are acute, lancinating and bilateral. Gonorrheal antecedents are liable to induce a tendency to ankylosis. A general douche-massage on a sloping table with two masseurs working on the spine is the final touchstone which differentiates the curable simple and pseudo-neuralgic spondylosis from the variety with ankylosis.

Diazo-Reaction in Typhoid Fever. E. SACQUEPEE.—The diazo-reaction was negative in only 17 of the 567 cases of typhoid fever which Sacquepée has collected, including 23 personal observations. Its final disappearance indicates speedy defervescence. It may vanish without warning at any time, but its persistence in spite of the downward temperature curve is an indication of some complication or of an associated disease such as peritonitis or tuberculosis.

September.

Diagnosis of Tuberculous Meningitis. MARCAN-MUTZNER.—Two cases are described showing that there may be mononucleosis of the cerebrospinal fluid in the absence of tuberculous meningitis, and that the latter may be accompanied by a polynucleosis.

Presse Medicale (Paris), October 23.

Gummatous Lesion in Frontal Lobe Simulating Lesion in Rolandic Region. G. DIEULAFOY.—A man of about 40, with a history of old syphilis but otherwise in good health, suddenly developed Jacksonian epilepsy in the night with other symptoms of a gummatous lesion so advanced that death ensued in a few days. The symptoms plainly localized the lesion in the region of Rolando but the autopsy disclosed that it was in the first convolution of the left frontal lobe. Lepine has witnessed three similar cases and Lowitz and Chipault have also published a case each in which the supposed site of the lesion was trephined. The region of Rolando was found intact and the autopsy later revealed the tumor in the frontal lobe. There were no peculiarities in the Jacksonian epilepsy in these cases to differentiate the frontal from the Rolandic type, but there is no record of the crural type of epilepsy in these frontal cases, and this may possibly prove a point to remember in the differentiation.

October 30.

To Avoid the By-Effects of Spinal Cocainization. GUINARD.—The water used in the solution of cocain is probably the cause of the headache, hyperthermia, etc., observed sometimes after spinal cocainization. Guinard has completely avoided all these by-effects by using the patient's own cerebrospinal fluid as the vehicle. He draws 60 to 80 drops of the fluid into a receptacle while 6 or 7 drops of a concentrated solution of cocain in the proportion of 1 cg. of cocain to 2 drops of water are automatically added to the cerebrospinal fluid as it flows. The mixture is aspirated into the syringe and reinjected into the subarachnoid space at once. Fifty operations performed under spinal cocainization by this method were not followed by a single post-cocainic incident in any case.

Four Cases of Tetanus Cured by Intracerebral Injections of Antitetanus Serum. LETOUX.—The conditions of success are early injection of as much as 20 c.c. of the serum for each hemisphere. Letoux injects it in the most prominent portion of the frontal eminence, with a needle 6 cm. long. The injection required seven to twenty-seven minutes. The serum does not cure the nerve cells already affected by the poison, but it protects the others against it. Subcutaneous injections have no action on the poison except as it is passing from the primary wound to the nervous axis. Consequently they are only useful as a preventive measure, while intracerebral injections are curative.

Compress Method of General Anesthesia by Ethyl Chlorid. A. MALHERBE.—Two to four grams of ethyl chlorid are poured on a compress which is then applied to exclude the air over the mouth and nose of the subject. Narcosis is complete in twenty to forty seconds, and lasts three or four minutes, with no stage of excitement. It can be prolonged by new applications of the chlorid, thus enabling operations of fifteen to twenty minutes to be performed with ease. For longer operations, Malherbe supplements the chlorid with chloroform.

Vaselin Subcutaneous Prothesis. DELANGRE.—Suppuration around the mass of paraffin was observed in 3 out of 17 cases in which paraffin had been injected into the tissues for cosmetic or utilitarian purposes. Among the cases cured by this means was one of vesico-vaginal and one of entero-vaginal fistula, and the restoration of a lower lip after extensive resection during the extirpation of a cancer.

Aid to Diagnosis of Cerebral Compression. VIDAL.—In the lack of any definite local symptom or anamnestic data on which to base the diagnosis, in a case of generalized epilepsy, Vidal had the patient inhale amyl nitrite. The intense congestion of the brain which it induces entails an epileptic seizure in such cases when there is any obstacle to the free expansion of the brain. In this case the immediate fulminating seizure confirmed the diagnosis of cerebral compression, and hemicraniectomy disclosed several tumors in the dura mater. Their ablation was followed by complete cure of the epileptic symptoms.

Surgical Diagnosis by Means of the Blood. T. TUFFIER.—During the last two years Tuffier has had the blood examined in 60 dubious cases to determine the existence of suppuration, tumors or internal hemorrhage, and he announces that information can thus be obtained, of the greatest value to the surgeon. In one case for instance, osteo-sarcoma had been diagnosed, but the blood indicated suppuration, and Tuffier followed the latter indication with success. In all cases of suppuration, irrespective of their extent or localization, the blood shows hyperleucocytosis of the polynuclears, with increased numbers of red corpuscles and diminution of the hemoglobin in them. In case of tumors of connective tissue origin, such as sarcomata, there is also a polynuclear hyperleucocytosis but much less extensive than in case of suppuration. In the latter the white corpuscles attain three and four times their normal proportion. In case of tumors of epithelial origin, the hyperleucocytosis involves the mononuclears, at least in the first stages of the neoplasm before it is complicated by infectious processes. This mononucleosis accompanying cancer is characterized by the decrease in the amount of hemoglobin contained in the red corpuscles, while the number of the latter is not diminished. In case of anemia from hemorrhage the total number of reds is diminished but their composition is unchanged. It is possible thus to differentiate a cancer from an ulcer of the stomach, and a cancer of the uterus from a hemorrhagic metritis. Equally important information can be derived by centrifugalization of the cerebrospinal fluid after a traumatism. The presence or absence of figured elements in the fluid will establish the existence or absence of an intrameningeal hemorrhage. In a number of dubious cases Tuffier found this measure a most important means of differentiation, otherwise impossible.

November 2.

Abdominal Surgery After Bullet Wound. REYNES.—A young man of 30 was shot in the abdomen and although the general condition was excellent, pulse and temperature normal, with no signs of hemorrhage or incipient peritonitis, laparotomy was done seven hours after the wound. Extensive hemorrhage was found proceeding from injured mesenteric arteries, and eleven perforations of the intestines with stercoral filtration. The anesthesia was done with A.C.E. and the operation lasted three hours. Recovery was smooth and rapid.

Semaine Medicale (Paris), October 23.

Treatment of Pannus with Radiating Heat. J. HAMBURGER.—The patient lies on the operating table. A few drops of a 3 per cent. solution of cocain are instilled and the eyeball held immovable by an assistant. The thermocautery is then approached close to the eye without actual contact with the tissues, thus submitting the pannus to the radiating heat. The vessels nourishing the pannus are then sectioned with the tip of the thermocautery and after instillation of atropin and insufflation of iodoform a light dressing is applied. The vascular injection rapidly disappears, the exudate is resorbed and the cornea regains its transparency.

October 30.

Ventroscopy During Operations by the Vaginal Route. DMITRI DE OTT announces that one of the great disadvantages of the vaginal route can be entirely obviated by using a small incandescent lamp no larger than a walnut, which can be introduced into the abdomen through the vagina. If the outer wall of the abdomen is seized with forceps near the umbilicus and lifted up, it is possible by the brilliant illumination afforded by the little lamp to see not only all the small pelvis, but the appendix, cecum and even parts of the stomach, liver and gall-bladder. The round ligaments and the posterior wall of the bladder are especially visible. The lamp can be permanently fastened inside the abdominal cavity by inserting it in the concavity of the retractor applied at the upper angle of the incision. By this means the light does not shine into the operator's eyes while the cavity below is brilliantly illuminated. The Trendelenburg position enables better oversight of the abdominal cavity. De Ott always tampons the opening between the vagina and the peritoneal cavity before raising the pelvis, in order to filter the air that rushes in as the intestines sink down toward the diaphragm.

Cure of Incontinence of Urine by Epidural Injection of Cocain. Albarran and Cathelin announce that they have succeeded in improving or actually curing fifteen patients of incontinence of urine by one to several injections of 1 c.c. of a 2 per cent. solution of cocain. The only two cases which resisted this treatment proved to be incontinence resulting from tuberculosis of the urinary organs. They also found that equally good results were obtained from the injection of 15 to 20 c.c. of artificial serum. A single injection was sufficient to cure nocturnal incontinence in three children.

Allg. Wien. Med. Zeitung, September 10.

Lavage of the Stomach for Nervous Vomiting. A. Benderski.—A dozen and more cases are related all improved and a number permanently cured by rinsing out the stomach with warm water as a method of treatment for nervous vomiting. The benefit invariably derived should recommend lavage of the stomach as the first step always in such cases.

Berliner Klin. Wochenschrift, October 21.

Physostigmin as a Remedy for Paralysis of the Intestines. C. Von Noorden.—Veterinarians have long appreciated and utilized the alkaloid derived from the Calabar bean—eserin, as a means of inducing tetanic contraction of the relaxed intestine, with consequent anemia and evacuation of its contents. Physicians have always been timid in regard to it, and it has never been applied on man for this purpose although it has proved so successful in subcutaneous injections in horses, in experiments on animals and in ophthalmology. Von Noorden now reports five cases in which rapid action was necessary on account of threatening heart failure or other cause. One patient was a physician who had for years exhibited symptoms of a heart defect, controllable by digitalis. Eight days after a radical operation for inguinal hernia, extreme tympanites developed and the forcing up of the diaphragm interfered with the respiration and heart action. Physostigmin was administered three times during the day in 0.5 mg. doses. Flatus passed abundantly during the night and the abdomen was apparently normal the next day. In another patient the abdomen was distended by gas to a circumference of 84 cm. Prompt relief was obtained by administration of 0.75 mg. physostigmin four times during the day. The patient was a woman of 53. The results were equally prompt and satisfactory in two cases of typhoid fever. The physostigmin was given in the form of the salicylate, in a powder, rejecting every sample that had turned red. Atropin is an antidote to physostigmin. Fraser has reported that it will save animals after ingestion of 3.5 times the smallest fatal dose.

Subacute Weakness of the Heart in the Course of Cardiac Defects. C. A. Ewald.—A remarkable case is described only to be explained by the assumption that a long-existing cardiac defect—still in the stage of symptomless compensation—suddenly became complicated by a myocarditis. The heart action was intensely disturbed by this combination, but under the influence of heart tonics and sedatives, the removal of the obstacles to the peripheral circulation, possibly supplemented by an inherent tendency to recovery, the morbid process retrogressed without entailing any essential injury of the heart muscle. During the course of two years the condition of the patient grew constantly worse until it seemed absolutely hopeless. He had been kept under the influence of morphin for nine months, and the edema had required draining for three weeks. The sputum had been frequently hemorrhagic and of the color noted in case of thrombosis and embolism of the lungs. Recovery was rapid after it once commenced, and was complete except for the indications of the previously existing compensated cardiac defect.

October 28.

Influence of Retention of Bile on Secretory Functions of Stomach. S. Simnitzky.—This article reports the results of 81 examinations of the gastric functions in 7 cases of catarrhal icterus, 1 of Weil's disease with liver colic, 3 of hypertrophic cirrhosis of the liver and 1 of icterus from compression of the bile duct by a neoplasm in the pancreas. The research was conducted at Botkine's internal clinic and at Pavloff's laboratory of physiology at St. Petersburg. It conclusively demonstrated that the retention of bile increases the secretory functions of the stomach. Hyperacidity was evident in every case and it subsided parallel to the diminishing retention of bile. The hyperacidity was due almost exclusively to uncombined hydrochloric acid, showing an exaggeration of the secretion. As the retention of bile diminished, the chemistry of the stomach returned likewise to normal, while on the other hand, the hyperacidity returned with recurring retention of bile. Experiments on dogs confirmed these clinical findings. The secretion was increased both during the first and later hours after a meal, showing an exaggeration of both the "psychic" and the "chemical" secretion. He found in sixty tests on 3 dogs with gastric fistulæ made according to Pavloff's method, that the nature of the food had a certain influence on the secretion in case of artificially induced stasis of bile. After ingestion of milk the secretion increased 100 and 400 per cent. over the normal secretion in such circumstances. After a meal of cooked whites of egg it increased over 200 per cent., while the cooked yolks of egg caused an increase of 50 to 400 per cent., accompanied, however, by nausea, vomiting, thirst, diarrhea and loss of appetite. In normal conditions the amount of hydrochloric acid secreted varies very little during the hours after a meal, but in case of retention of bile the first intense hypersecretion rapidly diminishes after the first hours, indicating exhaustion of the glands after their first excessive activity. This is an important fact to bear in mind in treating such conditions, so as to avoid playing into the hand of the morbid process.

Centralblatt f. Bakteriologie (Jena), October 8.

Influence of Heat on Tubercle Bacilli in Milk. C. Barthel.—Tubercle bacilli in fresh milk can be killed by heating to 176 F. for even one moment. But the same heat applied to milk that had been standing until it was slightly sour, failed to kill the bacilli even in five minutes. In testing milk, therefore, the acidity of the samples should be that of normal milk in order to obtain results that can be compared.

October 15.

Bacteriology of Typhoid Pneumonia. A. Dieudonne.—Stuehlern has published two cases of typhoid lobar pneumonia and Dieudonné describes another. All were differentiated by the hemorrhagic character of the sputa. The typhoid bacilli were found in the sputa late into convalescence as in the case of plague pneumonia.

Centralblatt f. Gynaekologie (Leipsic), October 5.

The Eclampsia Question. K. A. Herzfeld.—In looking over the reports of 18,000 dissections at the Vienna Institute of Pathology during the last ten years, 81 cases of eclampsia were found. In 38 the record described indications of chronic nephritis, in 25 of parenchymatous degeneration of the kidneys and in 18 compression of both ureters. Compression of the ureters was observed in the majority of cases of eclampsia in primiparæ, first exhibited during the dilating stage with a fetus at term. In 32 out of the 81 cases a hemorrhagic hepatitis was mentioned, with compression of the ureters in 4: in 28 there was parenchymatous degeneration of liver and kidneys with likewise compression of the ureters in 4. In 21 cases no macroscopic alterations were noted in the liver but compression of the ureters had occurred in 10. Chronic Bright's disease with more or less severe changes in the heart was found in 46.6 per cent., bilateral compression of the ureters in 22.3 per cent. and acute nephritis, etc., in 31.1 per cent. The conclusion from these data seems evident that in the majority of cases of eclampsia there is an existing predisposition from some lesion or affection of the urinary system. This assumption is further sustained by the fact that the cases in which eclampsia appears in the early stages of pregnancy are considered the most severe. They are almost inevitably cases of pre-existing severe nephritic processes, an important point for the prognosis. Eclampsia is not a uremic process; it seems to be rather an intoxication of the maternal organism from the waste products of its own and the fetal metabolism.

Previously existing disturbance in the uropoietic system hinders the elimination of these waste products and favors their accumulation in the blood. Another fact noted by Herzfeld was that compression of the ureters had been noted in every case in which the eclampsia had commenced in a primipara at the dilating period of delivery. It was never found in a pluripara nor in a primipara in whom the eclampsia had commenced during the early stages of pregnancy or postpartum. Consequently, when in presence of a primipara in eclampsia, commencing during the dilating period of delivery, compression of the ureters and anuria can be assumed with almost certainty, and delivery should be hastened. Cesarean section is the most rapid and sparing means of delivery under these circumstances.

Plastic Method of Treating Vesico-Vaginal Fistula. N. WOLKOWITSCH.—Eight very extensive and practically inoperable cases of vesico-vaginal fistula were cured by mobilizing and drawing down the lower portion of the uterus and suturing the side of the cervix over the defect. The uterus has a tendency to rise and resume its former position with the exception that the anterior lip of the cervix is fastened a little lower than normally. The bladder was evacuated and irrigated through a very small high incision in a few of the cases. It was found that systematically repeated distension of the bladder proved successful in developing the faculty of retention.

Dermatologische Zeitschrift (Berlin), October.

Connection Between Tabes and Preceding Mercurial Treatment. NEISSER.—Only 53 per cent. of the cases of tabes observed by Neisser had received previous mercurial treatment. In 41 per cent. a single course of mercurial treatment had been followed, and several courses in only 5 per cent. These figures show the lack of any connection between preceding mercurial treatment and the development of tabes later.

Etiology of Eczema.—Bockhart, Bender and Gerlach presented communications on this subject at the recent Naturforscher Congress, describing their research and establishing that the staphylococci are frequently found numerous in the skin in health, collected in the follicles. The vesicles which develop over the follicles contain the germs from the first, and in a later stage the staphylococcus is found almost in a pure culture in all the vesicles. The staphylococcus produces two quite different toxins, staphyloplasmin and staphylotoxin. The staphylococci always induced impetigo in the numerous tests, while injection of the products of their metabolism invariably induced eczema. The inoculations were made by the scientists on themselves.

Roentgen Treatment of Hypertrichosis. HOLZKNECHT.—Permanently favorable results follow Roentgen treatment of hypertrichosis in elderly individuals with a close and heavy growth of hair. Young persons with a finer growth of hair are not treated by this method, as the benefits derived do not counterbalance the harm done by the atrophy of the skin.

Deutsche Med. Wochenschrift (Leipsic), October 31.

Functional Test of the Liver. H. STRAUSS.—The relations of the liver to processes of neutralization of poisons and to the combustion and utilization of albuminoids and carbohydrates have been studied at Senator's clinic during the last two years with a purpose to determine some simple clinical test of the functional activity of the liver by the composition of the urine. Eight patients with liver affections, after a test dinner, repeated twice, were given 20 gm. of sodium butyrate. Investigation of the urine afterward showed an increase in the elimination of volatile fatty acids in six cases. The two negative cases were one of carcinoma of the liver and one of occlusion of the common bile duct. The tests of the function of the liver in respect to the albuminoids were fruitless, but important results were obtained in respect to the metabolism of the carbohydrates. These tests were based on previous research conducted by Sachs under Strauss' directions, which demonstrated that frogs deprived of their livers were less tolerant to levulose than intact frogs. The subject was investigated thoroughly on 29 patients with liver affections and 58 presumably healthy persons. The test was the administration of 100 gm. of levulose fasting. The urine emitted during the four following hours was investigated by Trommer's, Selivanoff's and the fermentation tests and polarization. The results proved the existence of levulosuria in 90 per cent. of the liver patients, and in 10 per cent. of the 58 healthy subjects. It is possible that the latter included some cases of mild, latent liver affections responsible for the few positive results. This alimentary levulosuria appeared generally in the first and second hours, more rarely in the second and third, and amounted to a proportion of at least 1 per cent. of the total levulose which had been ingested. The three cases of liver affections in which the test was negative included one of atrophic cirrhosis of the liver accompanied by severe diarrhea, which possibly hindered the absorption of the levulose, and one of acute cholelithiasis. The conditions were evidently very different from those entailed by a chronic affection. The third was a cyst in the liver which had been stationary for nine years and ample compensation had probably developed. The results of this research establish that in levulose we possess a means by which we can test the functional capacity of the liver in a certain direction more effectively than by any other method known to date. The results are the more remarkable as we know that healthy subjects and also diabetics, tolerate levulose better than dextrose, and von Mering has demonstrated that dogs deprived of the pancreas are able to form glycogen out of levulose even after they have lost the faculty of forming it out of dextrose.

Elimination of Typhoid Bacilli in the Urine. SCHUEDER.—Typhoid bacilli may be eliminated in enormous quantities in the urine of typhoid fever patients. In 671 tests of the urine instituted by Schueder on 22 patients the bacilli were discovered in the urine in 22.7 per cent. Most of them were severe cases with complications on the part of the kidneys, indicated by albuminuria, but they were occasionally found in the milder forms. This elimination of bacilli through the urine may occur at any time during the disease or convalescence. The latter occurs most frequently and the bacilli can be detected in the urine weeks after final defervescence. Nineteen other writers have already reported similar findings and noted the coincidence of albuminuria. Their tests were positive in 177 out of 599 cases of typhoid fever. The urine, therefore, must be considered capable of imparting infection and also the water in which typhoid patients or convalescents bathe, as millions of bacteria may be discharged into the water if the patient happens to urinate during the bath.

New Standpoint for the Treatment of Albuminuria. EDEL.—Diuresis is promoted by improving the conditions of the circulation. This is proved by the increase after changing from the vertical position all day to the horizontal at night, by the lesser albuminuria in the afternoon and after the administration of diuretics, etc. All such factors promote diuresis by improving the conditions of the circulation, and the increased diuresis abolishes the albuminuria. Edel has been treating albuminuria on these principles, stimulating the circulation by mountain climbing and other physical exercises, supplemented by respiratory gymnastics, and has found this treatment very effective as an adjuvant in the cure of albuminuria.

Natural Means of Defense Against Angina in Scarlet Fever and Diphtheria. L. KUERT.—The movements of the muscles in swallowing are an effective aid in the defense of the throat against infectious processes. Kuert therefore recommends the sucking of candy, etc., as a preventive and curative measure in scarlet fever and diphtheria.

Jahrbuch f. Kinderheilkunde (Berlin), September.

Etiology of Chorea Minor. T. FROELICH.—In the history of 47 cases of chorea minor at Christiania acute rheumatism was noted in 31.9 per cent.; some other infectious disease in 8.5 per cent., and infection of an unknown nature in 34 per cent. No infectious antecedents could be discovered in 25.5

per cent. The girls outnumbered the boys by 39 to 8, and the manifestations of the affection were more pronounced in them.

October.

Inhalations of Oxygen for Children. E. Hagenbach-Burckhardt.—Cyanosis is immediately relieved by inhalations of oxygen. It has proved so valuable in cases of diphtheric stenosis in the writer's experience at Basle that a large amount is kept in the diphtheria ward constantly ready for use. The general condition of the children usually improves rapidly after the relief of the cyanosis by the inhalations. It has been the means of saving life in certain cases and also in a few instances of heart disease in adults.

Mitteilungen a. d. Grenzgeb. (Jena), viii, 4 and 5.

Operative Treatment of Phlegmonous Meningitis. O. Witzel.—The possibility of successful surgical intervention in cases of phlegmonous meningitis is demonstrated by Witzel's experience with four patients. Two were cured and two were improved but succumbed later to the recurrence of the meningitis. He found it necessary to resect the skull until sound arachnoid was reached. The phlegmonous process is liable to extend between the convolutions of the brain in a zone of cloudy infiltration. The entire process and the zones of infiltration should be covered with an absorbing and aspirating tampon. Even very extensive defects in the skull can easily be remedied by inserting a screen of silver wire in a secondary operation, as he has demonstrated again and again. The drawback of the necessity of this secondary intervention is but a trifle in comparison to the importance of success in the primary intervention. The tampon must be applied in such a way that its removal later will not mechanically injure the brain nor entail a breach in the wall of granulations around the meningeal space. He accomplished this by working a long strip of gauze between the dura and the surface of the brain, arranging it in concentric circles like a wreath about 4 cm. wide, around the edge of the gap in the bone, between the surface of the brain and the skull. A second, flat tampon is laid over the open space in the center. This is changed in a few days before granulations form. The wreath portion should be left undisturbed for about fourteen days. If it is twisted like a rope as it is being removed, it comes away without bringing any of the granulations with it.

Muenchener Med. Wochenschrift, October 29.

Development of Affections of the Organs After a Contusion. Jordan.—This article was prepared at the request of the committee of organization of the recent Naturforscher Congress. The conclusions of the extensive investigations of the subject in various clinics, etc., are that a single contusion can be incriminated in the development of a tumor only in a very small percentage of cases. Only a minimal importance can be ascribed to trauma in case of carcinoma. Sarcoma occurs more frequently than carcinoma after traumatism, but the proportion is still very small. Preceding trauma to be a conclusive factor in the development of a tumor, must have been accurately observed by a physician and its topography recorded, and the tumor must correspond exactly to the site of the incriminated contusion. The interval between the time of the trauma and the development of the tumor must coincide with the period of evolution of the tumor. There must also be proof furnished that an incipient tumor had not already existed at the spot. As these conditions are rarely possible of realization, it is practically impossible to adduce clinical evidence in regard to the causal connection between the trauma and the tumor. The conditions are more favorable in case of surgical tuberculosis and a causal connection can be assumed when the injury is conclusively proven, when the lesion develops at the point of the contusion and when the first symptoms develop immediately after the injury or after a reasonable interval, not exceeding a few months. An unmistakable causal connection can be accepted when osteomyelitis develops at the point of the contusion immediately after the trauma, within a few days to two weeks at farthest. The myelitis may develop in a subacute or chronic form and the abscess may not appear for several months, but the first symptoms must develop within the first few weeks to denote any connection with the trauma. As the consequences of a slight contusion are transient, a long period of incubation for an osteomyelitis excludes the possibility of its dependence on the trauma. The question as to a causal connection between a contusion and appendicitis can be decided in the affirmative when the cecal region was involved in the traumatism and when the manifestations of appendicitis appear in an acute form in a previously healthy person, immediately after the trauma. In case the subject had had previous attacks of appendicitis, or symptoms in the right iliac fossa had indicated some chronic inflammatory changes in the appendix, fatal perforation following upon the contusion must be attributed to the trauma as the causal factor.

Therapeutische Monatshefte (Berlin), October.

Sea Air for Nervous Affections. Ide.—When sea air is ordered for a neurasthenic patient he usually rushes down to the seashore, spends all his time on the beach, frets more or less over the expense and returns after two or three weeks to make up by extra work for the brief holiday. The result is an exaggeration of the nervous trouble. The sea is too exciting for such patients at first. They should be gradually accustomed to the air and surroundings, but if these precautions are observed, there is nothing to compare with the effects of sea air in nervous affections. Its effect on the skin is like that of hydrotherapy, but it has the advantage of oxygenating the system at the same time. Ide advises that such patients should stay at a house some little distance from the beach, with quiet, sunny rooms sheltered from the wind. After thoroughly resting from the fatigue of the journey they should seek sheltered spots out of doors and after three or four days walk down to the beach several times a day, resting afterward each time, warmly covered. If there is little sleep or appetite the walks must be restricted and the patient should rest in bed several times a day or permanently. The sea air makes such demands on the metabolism that the stays on the beach should not be allowed to increase the metabolism beyond what the powers of digestion and assimilation are able to keep pace with. The patient should always rest for an hour before each of the principal meals of the day. As the strength increases four to six hours a day can be spent on the beach. Long trips and excursions should be carefully avoided. Ide's remarks apply more particularly to the resorts on the coast of the North Sea.

Treatment of Fever in Pulmonary Tuberculosis. A. Meyer.—A temperature of 37.3 C. (99 F.), is fever. A tuberculous patient with this temperature should go to bed and not get up again until he has been free from fever for three days. Meyer has known cases in which the patients stayed thus in bed for six months and more, and then regained complete health. Reclining is not sufficient. The patient must be actually in bed. He practices in the Riviera and advises his patients not to open their windows at night during inclement weather; fluid food as long as the temperature is over 38.3 C. (101 F.), as in case of fever from any cause, with several quarts of milk, raw eggs beaten up with wine, eggnog, etc., eight times a day with soups of all kinds, etc.; no antipyretics. Most hydrotherapeutic measures are too fatiguing, but a cold water bandage around chest and back is an excellent aid in reducing the fever.

Therapie der Gegenwart (Berlin), October.

Uric Deposits in the Body and Means of Dissolving Them. W. His, Jr.—A drug to be effective in dissolving out the deposits of urates in the body must be able to form a combination with uric acid which is more readily soluble than the acid itself and its alkaline salts. It must pass unchanged through the body and exhibit its dissolving powers at the points where they are needed. It must be harmless even in protracted use. The alkaline salts and diamins have proved their inefficiency considered from this standpoint, but nuclein and thymus acid and formaldehyd have demonstrated that they are able to pass undecomposed through the organism and appear unchanged in the urine, where they form exceptionally soluble

compounds with the uric acid and glycocol. They have not yet been applied to dissolve gouty tophi and deposits in the joints. Stimulation of the circulation by local applications is the best method known to date for this purpose. Neither the alkalies nor the diamins have proved effective in this respect. Urotropin comes very near to fulfilling the conditions of the ideal drug to dissolve uric deposits as it gives off formaldehyd in the urine. But even as much as six grams are inadequate to fasten the total uric acid in the urine of a single day, much less to dissolve already formed concrements. Its dissolving power is unquestionable, but its action is too weak for practical results.

Buttermilk as Infant Food.—Salge and Heubner report that after extensive tests their experience has confirmed the assertions of the Dutch physicians in regard to the way in which healthy and sick infants thrive on buttermilk. It must be less than twenty-four hours old, made from sour cream, mixed with sugar and flour and brought to a boil three times. It represents 714 calories to the liter. The stools are very fine but scanty. The weight shows a regular upward curve. Salge found it especially beneficial as the first food after dyspepsia and acute intestinal disturbances, in atrophy, and for supplementing nursing.

Manipulative Treatment of Wry-Neck. LORENZ.—The bloodless method of treating deformities of the hip-joint, etc., which has made Lorenz's name so familiar, has been applied to the treatment of wry-neck with complete success in a number of cases he reported at the recent Naturforscher Congress.

Operative Treatment of the Lungs. GARRÉ.—The best results have been obtained in cases of echinococcus of the lungs —90 per cent. cured. Garré reports 18 cures in 22 patients with gangrene of the lungs, and 17 cures in 35 cases of bronchiectasis. Lenhartz has reported 4 successes in 4 cases of bronchiectasis and 11 in 23 of gangrene. The gangrene was nearly or quite total in the unsuccessful cases. Incision and drainage are mentioned in the 47 cases of surgery of the lung that have been reported.

Chlumsky's Absorbable Magnesium Button.—The new intestinal button is made of pure magnesium after the pattern of the Murphy button with some slight modifications. It remains unaltered in the intestines for four weeks except that the outer surface becomes softer. The inner part then dissolves in about 10 days and the remainder in 14 to 16. The dissolving can be hastened or retarded by making the button thinner or thicker.

Hospitalstidende (Copenhagen), September 25.

New Method of Differentiating and Treating Cancer. HOWITZ.—The success obtained by freezing the tissues in the treatment of ulcus molle and of lupus, suggested that it might be of use in the treatment of cancer. Howitz therefore experimented with it and found his anticipations more than fulfilled. He reports eight patients with cancer of the uterus and vagina and two with cancer of the breast, treated by first curetting away as much of the malignant growth as possible, and then spraying with ethyl chlorid. He found that sound tissues turn rapidly white under the spray while the cancerous masses show little if any change in color. By this means it is possible to differentiate malignant disease and locate the outer limits of its extension. After the cancer has been curetted the tissues turn white under the spray but much slower and less completely than in case of sound tissue. Rapid freezing of the tissues is therefore a favorable sign for the prognosis. In numbers of cases in Howitz's experience, the microscope has confirmed the non-malignant character of a suspicious neoplasm which turned promptly white under the spray. Copious suppuration follows the spraying, then the surface granulates and normal epithelium forms. After a carcinoma of the uterus has been sprayed in this way, the uterus, if fastened by adhesions from the affection in the parametrium, regains its movability, possibly owing to retrogression of some inflammation of the uterus. This fact may prove important as an indication for extirpation of the organ, as it indicates the possibility of a permanent cure after ablation. Menstruation returns more or less to normal, the patients gain in weight, partly from the removal or destruction of the malignant masses and partly from the superabundant feeding which he always institutes as part of the treatment. He makes an earnest appeal to physicians to test this simple, absolutely harmless, inexpensive and effective method of treating malignant disease. He first curettes thoroughly, and, if necessary, cauterizes with the Paquelin and tampons with gauze. After an interval of a few days he applies the freezing spray for one to five minutes, then rinses and dries the surface of the neoplasm. He repeats this refrigeration every third day at first, later with longer intervals. Whenever a suspicious patch appears he curettes anew. Recovery was impossible on account of the advanced stage of the cases in which he has tried the method to date, but the condition of the patients was immeasurably improved and life prolonged.

October 9.

New Points of View for Treatment of Intestinal Occlusion. SANDELIN.—Instead of seeking for the point of occlusion by bringing the intestines into the incision, Sandelin recommends making it large enough to insert the entire hand, and then feel around inside the abdominal cavity until the site of the trouble is found and the condition of the mesentery determined and straightened. When the site of the occlusion is found, the intestine can be brought up into the incision and treated as necessary. This internal palpation prevents the prolapse of any loop of the intestines and materially reduces the danger of collapse, paralysis and peritonitis.

Gazzetta Degli Ospedali (Milan), November 3.

The Blood in Tuberculosis. MIRCOLI.—It has been Mircoli's experience that tuberculous patients who expectorated blood were more easily cured than those who had no hemoptysis. He has also noted that in the early stage of tuberculosis there seems to be a tendency to hemorrhage outside of the respiratory passages, a kind of tuberculous hemophilia. He found in tests on man and animals that tuberculin diminishes the coagulability of the blood, but that 0.1 per cent. of Maragliano's antitoxin added to the tuberculin arrests this influence on the coagulability. The serum in the early stages of tuberculosis is very hemolytic.

Toxicity of the Excretions in Tuberculosis. SANTINI.—The pyogenic microbes play a prominent part in the toxic manifestations of tuberculosis, Santini has established by special research. This fact is a new proof of the importance of microbian associations in tuberculosis. Maragliano announces that he has succeeded in reproducing on animals lesions analogous to the tubercular in every respect, by means of the tubercle toxins alone.

Sodium Cacodylate in Tuberculosis. EVOLI reports that he has derived great benefit in pulmonary tuberculosis from the administration of sodium cacodylate. Maragliano has not found it any more effective than other preparations of arsenic or any substance which tends to increase the auto-defense of the organism, by stimulating the production of larger amounts of antitoxin.

Treatment of Tuberculosis by Nascent Iodin. A. CAVAZZANI.—The injection of an iodid into the blood of animals causes the generation of nascent iodin in the lungs when the animals are afterward forced to inhale the fumes of essential oil of turpentine. After thorough experimental confirmation of this fact, Cavazzani applied it to the treatment of pulmonary tuberculosis in the clinic, and now reports numerous complete cures from this nascent iodin method of treatment during ten years of experience. This simple and effective treatment has no inconveniences except that it requires months and sometimes a year or so before the cure is complete. Some of his patients have been completely cured for more than six years. He mentions that at first the symptoms become aggravated under this treatment. He applies it in both acute and chronic cases and has thus cured patients whose tuberculosis dated from several years.

The Heart in Chronic Deforming Rheumatism. RONCAGLIO.—Examination of thirty patients with chronic rheumatism, between 55 and 74 years old, showed endocarditic symptoms in only two, and in these the lesion was limited to the aortic ostium. This difference in its action on the heart is another proof in favor of the essential difference between acute articular rheumatism and the chronic variety.

New Patents.

Patents of interest to physicians, etc., November 5 and 12:

686,028. Catamenial sack. Adelaide Cortland, Pittsburg, Pa.
685,989. Seat for relieving piles. Peter Kendrick, Trenton, N. J.
685,894. Hot-water bag. Mortimer S. Williams, Newton, Mass.
686,578. Forceps. David F. Bowersox, Aaronsburg, Pa.
686,270. Inhaler. Wm. B. Dewees, Salina, Kan.
686,670. Dermal steaming apparatus for the head. Michael J. Fitzgerald, Boston.
686,281. Stomach pump. Walte Gerry, Ventura, Cal.
686,451. Hypodermic injector. Wm. M. Haynes, Sherman, N. Y.
686,616. Apparatus for testing strength and relative action of the external muscles of the eyes. Rudolph N. Johnquest, Ansonia, Conn.
686,332. Device for storing and administering serums. Herbert F. Prescott, Detroit, Mich.
686,338. Surgical safety appliance. Avery W. Ready, Jersey City, N. J.
686,535. Pocket eye-tester. Henry D. Reese, Abbeville, S. C.
686,638. Massage glove. Reuben E. Saffold, Rochester, N. Y.
686,425. Invalid lifting and moving device. Heinrich Sommerfeld, Canton, Kan.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Nov. 7-13, 1901, inclusive:

Walter K. Beatty, contract surgeon, from duty at the General Hospital, Presidio of San Francisco, Cal., to Fort Huachuca, Ariz., for post duty.

Perry Lee Boyer, lieutenant and asst.-surgeon, U. S. A., recently appointed, to proceed from Woodstock, Va., to Washington, D. C., reporting on arrival to Col. W. H. Forwood, president of the Faculty of the Army Medical School, for the prescribed course of instruction.

Alfred E. Bradley, captain and asst.-surgeon, U. S. A., from Fort Snelling, Minn., to Manila, P. I., via San Francisco, Cal., for assignment in the Division of the Philippines.

Peter J. A. Cleary, lieut.-col. and assistant surgeon-general, member of a promotion board at San Antonio, Tex.

Rudolph G. Ebert, major and surgeon, U. S. A., member of a promotion board at Vancouver Barracks, Wash.

Henry L. Gilchrist, lieutenant and asst.-surgeon, U. S. A., member of a promotion board at Vancouver Barracks, Wash.

Joseph B. Girard, lieut.-col., deputy surgeon-general, relieved from duty as chief surgeon, Department of the Columbia, and will proceed to Honolulu, H. I., to relieve Major Blair D. Taylor, surgeon, U. S. A.

James D. Glennan, major and surgeon, Vols., from the Division of the Philippines to San Francisco, Cal., reporting on arrival to the Adjutant-General of the Army for orders.

Herbert G. Gunn, contract surgeon, leave of absence from the Department of California extended.

Francis J. Ives, major and surgeon, U. S. A. (promoted from captain and asst.-surgeon, U. S. A.), to report in person to Col. Calvin DeWitt, assistant surgeon-general, president of the examining board convened at the Army Medical Museum Building, Washington, D. C., at such time as he may be requested by the board, for examination to determine his fitness for promotion, and upon the completion thereof to return to his proper station, or to the place of receipt by him of this order.

George W. Joan, lieutenant and asst.-surgeon, U. S. A., recently appointed and now at Danville, Ky., to Washington, D. C., for the course of instruction at the Army Medical School.

Frank R. Keefer, captain and asst.-surgeon, U. S. A., member of an examining board at Fort Monroe, Va., vice Capt. Alexander N. Stark, asst.-surgeon, U. S. A., relieved.

Franklin M. Kemp, captain and asst.-surgeon, U. S. A., former orders amended so as to direct him to proceed from the U. S. Military Academy, West Point, N. Y., to Manila, P. I., by the first available transport from New York City, N. Y., for assignment in the Division of the Philippines.

James S. Kennedy, captain and asst.-surgeon, U. S. Vols., from Fort Sam Houston, Tex., to Manila, P. I., via San Francisco, Cal., for duty in the Division of the Philippines.

Henry S. Kilbourne, major and surgeon, U. S. A., member of an examining board at San Francisco, Cal.

John S. Kulp, captain and asst.-surgeon, U. S. A., member of an examining board at the Army Building, New York City.

Clarence J. Manly, lieutenant and asst.-surgeon, U. S. A., from duty in the Philippines to San Francisco, Cal., reporting on arrival to the Adjutant-General of the Army for orders.

Charles F. Mason, captain and asst.-surgeon, U. S. A., member of a promotion board at San Antonio, Tex.

Raymond F. Metcalfe, lieutenant and asst.-surgeon, U. S. A., recently appointed, to proceed from Buffalo, N. Y., to Washington, D. C., to attend the session of the Army Medical School.

Robert M. O'Reilly, lieut.-col., and deputy surgeon-general, from Fort Monroe, Va., to San Francisco, Cal., for duty as chief surgeon, Department of California.

James M. Phalen, lieutenant and asst.-surgeon, U. S. A., recently appointed, to proceed from Chicago, Ill., to Washington, D. C., to attend the session of the Army Medical School.

Edwin W. Rich, lieutenant and asst.-surgeon, U. S. A., recently appointed, to proceed from Winthrop, Mass., to Fort Totten, N. Y., for duty at that post.

James F. Hall, lieutenant and asst.-surgeon, U. S. A., recently appointed, to proceed from Lowell, Mass., to Washington, D. C., to attend the session of the Army Medical School.

Allen M. Smith, captain and asst.-surgeon, U. S. A., from the Division of the Philippines to Baltimore, Md., as attending surgeon and examiner of recruits at that place.

Blair D. Taylor, major and surgeon, U. S. A., on being relieved from duty at Honolulu, H. I., by Lieut.-Col. J. B. Girard, will proceed to Fort Snelling, Minn., for post duty.

Frank H. Titus, major and surgeon, Vols., recently appointed and now at Portsmouth, Ohio, to proceed to Manila, P. I., via San Francisco, Cal., for duty in the Division of the Philippines.

Robert S. Woodson, captain and asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., reporting on arrival to the Adjutant-General of the Army for orders.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended Nov. 16, 1901:

Pharmacist J. Cowan, ordered to the Boston Navy Yard.

Surgeon G. T. Smith, detached from the *Amphitrite*, and ordered to the *Puritan*, when commissioned.

P. A. Surgeon R. S. Blakeman, detached from the Naval Hospital, Norfolk, Va., and ordered to the *Hartford*.

Asst.-Surgeon E. G. Parker, detached from the *Hartford*, and ordered home to wait orders, upon reporting of relief.

Asst.-Surgeon W. L. Bell, detached from the Naval Hospital, Cavite, P. I., and ordered home to wait orders, when relieved.

Asst.-Surgeon L. W. Bishop, detached from the *Independence*, and ordered to Naval Hospital, Cavite, P. I.

Asst.-Surgeon H. C. Curl, detached from the Naval Hospital, Cavite, P. I., and ordered home to wait orders.

Asst.-Surgeon G. M. Mayers, detached from the Pensacola Navy Yard, and ordered to the Naval Hospital, Cavite, P. I.

P. A. Surgeon C. M. DeValin, detached from Naval Hospital, Portsmouth, N. H., and ordered to the *Rainbow*.

P. A. Surgeon S. G. Evans, ordered to the Naval Hospital, Portsmouth, N. H.

Asst.-Surgeon W. H. Bell, detached from the *Franklin*, and ordered to the Naval Hospital, Norfolk, Va.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Nov. 16, 1901:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 27-Nov. 3, 1 case.
Indiana: Evansville, Nov. 2-9, 2 cases.
Kansas: Wichita, Nov. 2-9, 1 case.
Louisiana: New Orleans, Nov. 2-9, 7 cases.
Massachusetts: Boston, Nov. 2-9, 22 cases, 3 deaths.
Michigan: Detroit, Oct. 27-Nov. 2, 1 case.
Nebraska: Omaha, Nov. 2-9, 4 cases; South Omaha, Nov. 1-8, 2 cases.
New Jersey: Nov. 2-9, Camden, 3 cases; Newark, 29 cases, 2 deaths.
New York: New York, Nov. 2-9, 10 cases, 1 death.
Ohio: Cincinnati, Nov. 1-8, 1 case.
Pennsylvania: Allegheny City, Nov. 2-9, 2 cases; New Castle, Oct. 1-31, 4 cases; Norristown, Nov. 2-9, 10 cases, 1 death; Philadelphia, Nov. 2-9, 72 cases, 8 deaths; Pittsburg, Nov. 2-9, 1 case.
Tennessee: Memphis, Nov. 2-9, 1 case.
Utah: Salt Lake City, Nov. 2-9, 2 cases.
Vermont: Burlington, Nov. 2-9, 1 case.
Wisconsin: Green Bay, Nov. 2-10, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Oct. 19-26, 2 cases.
Belgium: Antwerp, Oct. 19-26, 3 cases; Ghent, Oct. 11-18, 2 deaths.
Brazil: Pernambuco, Sept. 6-30, 116 deaths; Rio de Janeiro, Sept. 15-Oct. 4, 205 deaths.
Canada: Nov. 2-9, Halifax, 7 cases; Quebec, 25 cases.
Colombia: Bocas del Toro, Oct. 22-29, 3 cases; Panama, Oct. 27-Nov. 6, 125 cases.
Egypt: Cairo, Oct. 7-14, 1 death.
Great Britain: Oct. 19-26, Liverpool, 1 death; London, 180 cases, 6 deaths
India: Madras, Oct. 5-11, 2 deaths.
Italy: Naples, Oct. 12-19, 31 cases, 1 death.
Russia: Moscow, Oct. 12-19, 4 cases, 4 deaths; Odessa, Oct. 19-26, 3 cases; St. Petersburg, Oct. 12-26, 4 cases.
West Indies: Curacao, Oct. 19-26, 4 cases, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, Sept. 15-Oct. 13, 11 deaths.
Mexico: Vera Cruz, Oct. 26-Nov. 2, 23 cases, 10 deaths.
India: Bombay, Oct. 8-15, 1 death; Calcutta, Oct. 5-12, 20 deaths; Madras, Oct. 5-11, 40 deaths.
Java: Batavia, Sept. 14-Oct. 5, 286 cases, 183 deaths.

PLAGUE—FOREIGN AND INSULAR.

Philippines: Manila, Sept. 7-28, 3 cases.
Brazil: Rio de Janeiro, Sept. 15-Oct. 13, 19 deaths.
India: Bombay, Oct. 8-15, 179 deaths; Calcutta, Oct. 5-12, 12 deaths.
Russia: Odessa, Nov. 10, present.

CLINICAL OBSERVATIONS IN PERICARDITIS.*

FRANK BILLINGS, M.D.
CHICAGO.

Pericarditis is essentially a secondary process occurring in the course of some general infection. The local manifestations may be so slight as to escape observation and the general symptoms to which the local disease may give rise may be obscured by the constitutional disturbance of the primary general infection. It happens, therefore, that the diagnosis of pericarditis is more often made at the autopsy than clinically.

Dry or plastic pericarditis may occur without symptoms, and unless careful auscultation be made daily in the course of rheumatic fever, pneumonia, etc., the chief diagnostic sign, the pericardial friction rub may escape detection.

With effusion, pericarditis may cause an irregular remittent or intermittent type of fever, usually of moderate degree; respiration is often hurried; the pulse frequently quickened and altered in rhythm and quality, and there may be nervous disturbance. However, these same general symptoms may be present as the result of the general infection of which the pericarditis is only a part, and unless careful physical explorations of the heart are made daily or at least often, even this ordinarily easily recognized type may remain undiscovered clinically.

My friend, Dr. Preble, will write under etiology, of the frequency of the disease, and naturally of the different infective types. He will show that the acute disease, as it occurs in pneumonia, is recognized usually in the postmortem room and not clinically.

The following case illustrates this point:

CASE 1.—G. H., male, aged 38, a laborer, was admitted to ward 8, Cook County Hospital, March 13, 1898. The illness began four days before admission with a chill, followed by fever, pain in the left lower chest aggravated by breathing and cough, general bodily aching and discomfort, and headache. The cough increased and he expectorated a tough, blood-stained sputum. There was constipation and loss of appetite. He had used alcohol and tobacco to excess.

On examination it was found that the lower left lobe was consolidated and there was bronchial breathing and moist râles heard over the affected lobe of the lung. It was noted that the cardiac area of dulness was somewhat increased, but no adventitious sounds were heard on auscultation. The urine contained a trace of albumin, and many hyalin and granular casts. The patient was slightly delirious. The temperature was 102 F., the pulse 120, regular and soft; the respirations 44.

The observation on the evening of the day of admission showed a pleuritic friction over both lungs in the mammary region. There was moderate cyanosis. The delirium was more marked. The pulse was quicker and weaker.

The patient died within thirty hours of admission, with the clinical diagnosis of left pleuro-pneumonia, right pleurisy, myocarditis and nephritis.

The autopsy revealed: Left lobar pneumonia; pericarditis, with 100 c.c. of sero-fibrinous fluid and the pericardial layers covered with fibrinous exudate; right cardiac dilatation; acute endocarditis; double fibrinous pleuritis; cloudy swelling of kidney; fatty degeneration of liver and acute splenitis.

In acute rheumatic fever, pericarditis is probably not so fatal as in pneumonia. This type is most often recognized clinically. This has placed rheumatism in the front rank as a cause of pericarditis. Occasionally, and especially in children, the rheumatic infection may be localized entirely in the pericardium, or more often the articular disturbance follows upon the local pericardial infection.

When so beginning, it may be ushered in by all sorts of symptoms.

It may occur suddenly and acutely with precordial pain or post-sternal or epigastric distress, or with dyspnea, in which the respiration may run to 50 or more per minute. In a child the writer has seen the respirations increased to 100 per minute, and this the first symptom or sign. The pulse is usually increased in frequency, but never at the beginning in proportion to the respiratory movements.

Again, the acute process may be ushered in by a few days of premonitory languor, anorexia, constipation, restless sleep, and slight disturbance of temperature, circulation and respiration.

In one case the writer has recently seen, in a boy of 7 years, the premonitory signs last named were, to the attending physician, suggestive of typhoid fever or malaria. Blood examinations excluded both of those infections and then a careful physical exploration of the chest revealed pericarditis with effusion.

When pericarditis occurs in the course of rheumatic fever, the most careful daily scrutiny is often necessary to recognize the onset. If preliminary observations have been made the local infection is usually easily recognized by the appearance of the pericardial friction rub, or by the presence of the effusion. The not unusual hyperpyrexia of rheumatic fever, with the associated delirium or other nervous disturbance, the rapid and often irregular respiration and the rapid heart action, may obscure the general symptoms of the accompanying pericarditis.

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section.

Endocarditis is not an infrequent condition in rheumatism with pericarditis, and acute myocarditis may also occur coincidentally. The infection of all three cardiac structures at one and the same time usually manifests itself in very profound general and severe local symptoms. The following case is one of rheumatic pericarditis, beginning, probably, primarily in the pericardium and subsequently in the joints.

CASE 2.—J. G., aged 22, single, American, engineer's helper, was admitted to Cook County Hospital, April 2, 1901. No history of rheumatism in the family. Patient had rheumatism 7 years ago. Typhoid fever 8 years ago and pneumonia when 7 years of age. Contracted gonorrhea, Jan. 5, 1901, and still suffers from it.

About March 12, patient was seized with sharp oppressive pain in the region of the heart, with dyspnea and inability to lie down because of a sense of smothering. Local hot mustard applications modified the pain. The next day the right knee became painful and swollen. Later the left knee, ankles, wrists and the smaller joints of the hands became involved. The pain in the heart region ceased after the first day and did not recur.

In about two weeks he became so much improved that he rose from the bed, but within 24 hours became speedily worse and was obliged to return to the bed and remain there on account of swollen, painful joints.

On admission, pulse 106, respiration 40, temperature 102 F. The skin was covered with sweat, the face flushed, the lips and nails cyanotic. The knees, ankles, wrists and some of the smaller joints of the hands swollen and tender to the touch. Fluctuation easily elicited in the right knee.

The thorax: Respirations rapid and shallow; chest bulging perceptibly in left mammary region; pulsation waves could be seen over the whole precordia, but most marked at the left fourth and fifth ribs. The apex-beat could be felt in the fifth interspace in the nipple line. Dulness extended over the whole precordia, from 2 inches to the right of the sternum to 2 inches to the left of the left nipple and to the level of the second left rib above. The outline of dulness was classical for pericardial effusion, a truncated triangle with the base downward. The dulness was marked in the right fifth interspace, obliterating the usual lung resonance at the angle formed by the liver, heart and lung. The wide extent, too, of dulness to the left, far beyond the normal relations of the apex to the left heart border, was noted. The lines of dulness shifted somewhat with the position of the patient.

On auscultation a to-and-fro friction murmur was heard at the second right rib and at the fifth left rib and the apex of the heart. A loud systolic murmur was heard at the apex, which was transmitted into the left axilla and heard plainly at the angle of the left scapula. A soft diastolic murmur was heard at the second right interspace near the sternum and was transmitted down the sternum. The second pulmonary sound was accented. Resonance was good over the whole left lung, excepting as noted in relation to the heart. There was dulness over the right lower thorax from the sixth rib downward, and lessened vocal fremitus, resonance and respiratory murmur in the same area. A few moist râles were heard over both lungs.

The liver and the spleen, not palpable. No glandular enlargements.

Slight, whitish, urethral discharge, in which a few gonococci were found in stained cover-glass slip.

The urine: Specific gravity, 1014; acid; albumin present; no casts.

Under the use of salicylates, alkalies, digitalis, ice bag to precordia, diluent drinks, milk diet, and absolute rest, the patient rapidly improved so that two weeks later all evidences of articular inflammation were gone. The pulse had fallen below 90, the temperature was practically normal (the highest temperature at any time was 102.8 F.) and the respirations to 28 to 30.

The outline of heart dulness had completely changed. The apex-beat was just within the nipple line and the left border of dulness just outside the nipple, while the dulness in the right fifth interspace was much less. Friction could still be heard at the fourth and fifth left interspace. The endocardial murmurs remained as before. There was doubtless an associated endocarditis, but this was implanted upon an old endocarditis, for the patient was told during the rheumatic attack which occurred 7 years ago, that the heart was involved.

The acute, rapid and benign course of this case is characteristic of the rheumatic form of the disease, as compared with that which occurs in some of the other infections. Not only was resolution rapid, but from the moment the patient was under the influence of antirheumatic medication, he became much less uncomfortable.

Pericarditis, usually with effusion, occurs like pleurisy in chronic nephritis. The associated uremic symptoms may mark the general symptoms due to the pericarditis, especially if there be myocardial changes, with accompanying pulse changes, altered respiration and disturbed sensorium due to uremia.

The following case is representative of this class:

CASE 3.—W. B., aged 40, carriage painter, married, was admitted to Cook County Hospital, June 18, 1900. Has suffered frequent attacks of articular rheumatism since he was 21 years of age. Had gonorrhea twice. Family history not obtainable.

Present illness began about May 1, 1900, with impaired vision, while he was at work. Dyspnea was soon after noticed and soon became especially aggravated when exercising or when lying down. Edema of the feet and legs gradually developed. He rose three or four times at night to urinate. Lost in strength and endurance; appetite became poor. Bowels were constipated. Had no severe headache and did not lose consciousness.

On admission, patient is poorly nourished and pale. Is restless in bed and remains in a semi-recumbent posture. Hands tremble. Facial expression indicate suffering and at the same time is apathetic. Mind clear, but perceptions slow. Skin cold and dry. Respirations rapid, superficial; expiration prolonged. Face puffy; eyelids edematous. Pupils equal, pupillary reflexes normal. Mouth dirty, teeth, tongue and post-pharynx covered with dry, clotted, dark blood. Radial pulse small and weak; radial arteries thickened.

Chest: Symmetrical. Resonance over right lung normal. Dulness over lower left chest, from a line on the level with angle of the scapula and nipple above, downward; upper line of dulness changes with position of patient. Vocal fremitus diminished over area of dulness; respiratory sounds diminished over area of dulness. No râles; no friction.

Heart: Apex-beat at sixth rib just inside nipple line. Dulness begins above at third rib—on the right half inch to right of the sternum, on the left one and a half inches to left of the nipple. No adventitious sounds were heard. The valvular sounds weak and faint.

Liver not palpable. Spleen not palpable. Edema of feet and legs.

Urine: Specific gravity, 1010; acid; much albumin and many hyaline and granular casts were found.

The respirations ranged from 26 to 30; the pulse from 88 to 100. The patient's chief complaint was dyspnea and fatigue. There was no pain and no cyanosis. He grew more and more apathetic and weaker, and died in coma on the second day after admission.

The clinical diagnosis was chronic nephritis, myocarditis with dilatation of left heart, right pleurisy with effusion, and uremia.

The autopsy revealed: Sero-fibrinous pericarditis, with a good deal of bloody fluid; both layers of pericardium covered with a layer of fibrin; left pleurisy with effusion; chronic myocarditis, with hypertrophy of heart, and chronic interstitial nephritis.

The form of the cardiac dulness and the relation of the apex-beat to the left border dulness should have made a diagnosis of pericarditis possible in this case.

Pyo-pericarditis, when due to the ordinary pyogenic cocci, presents the same difficulties in diagnosis as in pneumonia or other severe infections. This is true because the general infection produces such profound constitutional disturbance that the local condition may be overlooked.

The following case is illustrative of the point:

CASE 4.—F. S., aged 54, Polander, laborer, widower, was admitted to ward 4, Cook County Hospital, March 31, 1900. Patient says he was never ill before. He denies venereal disease. He takes alcoholic drinks in moderation.

About February 14, six weeks ago, the present illness began with a chill, followed by fever and sweat. There was dyspnea and soreness in the front of the chest. He coughed much and expectorated considerable yellowish sputa. There was backache and later swelling and soreness of the ankles. Three days ago a diarrhea commenced and has continued. He has had no appetite. Has lost in weight and strength.

On admission the patient is much emaciated. The face is flushed, the skin is hot and dry. Pupils equal and contracted. Lips parched. Tongue dry and brown. Breath offensive. Pulse 120 per minute, weak and regular.

Thorax: Large and symmetrical. Respirations 26 to 30 per minute; shallow and regular. Hyperresonance over both lungs. Moist râles heard over both lungs, greatest in number over posterior inferior portions. Respiratory murmur somewhat exaggerated but less loud over lower right lung behind. Expiratory sound prolonged everywhere.

Heart area obscured by overlying lung. Apex-beat not felt. Heart sounds are faint. No murmur and no friction rub heard. Liver not palpable. Spleen not palpable.

Skin of body and legs covered with small pustules varying in size from a pinhead to a pea. Left wrist and both ankles swollen and tender. Slight urethral discharge; cover slip preparations show intracellular, biscuit-shaped diplococci. Fluid withdrawn from fluctuating swelling over left external malleolus, showed the presence of pus. Cover slip, stained preparations and cultural tests proved the presence of staphylococcus pyogenes aureus in the pus from the abscess and also from the blood.

The Widal test was negative. A blood count showed 15,200 leucocytes per cu. m., polymorphonuclear leucocytes predominating.

The urine was reddish; acid; 1017; much albumin present; many granular casts, and a few red blood cells.

The patient's temperature was remittent in type. In the evening of the first day it reached 104.4 F. The pulse and respiration increased. The patient became delirious, had hiccough and became very weak. He died on the third day, the pulse reaching 140 and the respirations 56 per minute.

The clinical diagnosis was septico-pyemia, with chronic nephritis and chronic myocarditis.

The autopsy revealed: Sero-fibrinous pericarditis; a quantity of dark straw-colored fluid in pericardium; visceral and parietal layers covered with fibrin; recent adhesions between layers of pericardium and between pericardium and pleura; osteomyelitis of sternum; double fibrinous pleuritis; healed tuberculosis of both apices; left heart hypertrophy; calcareous degeneration of aorta; beginning cirrhosis of liver; miliary abscesses of spleen and kidney; chronic parenchymatous nephritis; purulent cystitis and urethritis, and purulent arthritis.

Tubercular pericarditis is much more common than is generally supposed. Of cases which come to autopsy probably 10 per cent. of all cases, acute and chronic together, will be found to be tubercular. Tubercular infection of the pericardium occurs probably in three ways. In tubercular septicemia, through the lymphatics or by direct extension from the mediastinal lymph glands, neighboring pleura, spinal column, etc.

Clinically it may occur as a dry or sero-fibrinous form. With tubercular processes recognized elsewhere in the body, or with the discovery in the pericardial fluid of tubercle bacilli microscopically, culturally, or by animal test, the diagnosis could be made. Otherwise the form of infection would not be recognized, and in practice it is not.

The following interesting case is one showing the difficulty of recognizing the etiologic infective bacterium:

CASE 5.—G. T., aged 29, single, colored, stone mason, was admitted to ward 4, Cook County Hospital, Oct. 2, 1899. The patient says there is no tuberculosis in the family. Father died of heart disease, mother and seven brothers and four sisters living and well. Had gonorrhea last year from which he made a good recovery. Denies syphilis. Has had measles, pneumonia, and malaria.

Five years ago had typhoid fever, and during convalescence suffered from right femoral thrombo-phlebitis, with gangrene of both great toes, so that amputation of toes became necessary. At the same time he suffered from ulcers of both legs. The right leg was worse than the left. There has been more or less edema of the right leg since the attack of phlebitis, and ulcers of the leg have usually been present.

The present illness began four weeks ago, with severe pain in the left costal margin in the splenic region. The pain became so severe that he was obliged to give up work and was sent to Cook County Hospital, where he remained a week in ward 22. The pain becoming less, he left the hospital. He attempted to work but was obliged to stop on account of general weakness. He had several slight chills during the next few days with fever, and five days ago a severe chill occurred, lasting a half hour. Some fever resulted, but no sweating. He feels weak, but there is no pain. The appetite is good and the bowels regular.

Examination: Large, well-nourished, healthy-appearing man. Expression natural, mind clear. Eyes, ears, nose, mouth and throat negative. Submaxillary cervical axillary, supratrochlear and inguinal lymph glands slightly enlarged and palpable.

Thorax, large, roomy. Expansion symmetrical.

Heart: Relative dulness increased; pear-shape with base downward, extending from the left second costal cartilage downward and outward to one and a half inches to left of the left nipple, and on the right to one inch to the right of the sternum. The right fifth interspace was flat on percussion. The apex-beat could be indistinctly felt in the fifth interspace just inside the nipple. There was friction to and from, a rub heard at the base of the heart and also along the left border near the nipple. There was slight bulging of the chest and somewhat lessened expansion of the left upper chest, but no impulse waves could be seen in the pericardium.

There was slight dulness over the lower right lung behind, with lessened respiratory murmur in the same area and also in the left infraclavicular region. Otherwise the lungs were negative. The pulse was soft, compressible, regular and 100 per minute.

The abdominal wall was rigid. The spleen not palpable. The liver extended, apparently below the costal margin in the mid-axillary line, but the edge was not palpable.

The lower extremities were edematous, the right more dropsical than the left. There were scars of healed ulcers on both legs and an unhealed varicose ulcer of the right leg. The right long saphenous vein was varicose and contained several phleboliths. There were stumps of amputated toes and deformities of the remaining toes. The condition of the lower extremities was the result of the typhoid fever of seven years before and had no relation apparently to the present illness. The temperature was but slightly increased.

On the third day an operating needle was inserted to a depth of one and a quarter inches in the fifth left interspace, one and a quarter inches to left of sternum; 10 c.c. of blood-tinged serum was obtained.

The urine: Amber color; acid; specific gravity 1023; no albu-

min; no casts; no bile. The centrifuge deposit revealed a few hyaline casts.

The patient became gradually worse objectively, although he expressed little feeling of discomfort. The temperature ranged from 99 to 103 F., with the minimum temperature usually in the morning and the maximum in the evening. The pulse was feeble, often irregularly intermittent and later presented the characteristic pulsus paradoxus. The respirations were shallow and ranged from 30 to 40, but the patient did not complain of dyspnea. There was a moderate amount of cough, and a little muco-purulent sputum. Repeated examinations of the sputa from day to day did not reveal tubercle bacilli.

A blood examination revealed 5,200,000 reds, 5750 white cells, and 88 per cent. hemoglobin (Fleischl).

It was noted on the fifth day that the precordial bulging was much greater and that dulness was increased. It extended above to the second rib on the right, to two and a half inches beyond the right border of the sternum, and on the left, to five and a half inches beyond the left nipple. The apex-beat could not be located. The heart sounds were very feeble and distant. No friction sound could be heard. There was relative dulness over the left infraclavicular and over the left scapular region. Broncho-vesicular breathing and a few moist râles could be heard in the same regions. The veins of the neck were distended, especially during inspiration. The patient was inclined to lie on the left side and was most comfortable with the head considerably elevated.

October 17, it was noted that the precordial bulging was greater. The dulness extended as high as the first rib, and six inches to the left of the nipple; on the right, dulness extended three inches beyond the right edge of the sternum at the fourth rib, and extended obliquely outward and downward just below the right nipple. The apex-beat could not be located. No friction was heard. The heart sounds were very feeble. The left lung dulness was the same as previously noted, but there were more râles, both moist and dry. The right lung gave negative findings. The pulse was feeble, especially during inspiration. The veins of the neck were much distended. Widal's test made at this and at subsequent periods, in the dilution of 1 to 10, showed loss of motility and incomplete clumping of the bacilli. This reaction was doubtless due to the attack of typhoid of seven years ago.

At this time the temperature was irregular in type, but lower on the average than when first admitted. It ranged from 97 to 102 F., but no longer followed the physiologic morning remission and evening exacerbation type.

The patient was still fairly comfortable. He made no complaint of pain, but had some dyspnea. He lay upon the left side with the head elevated. Cough was troublesome, but there was but little sputa. There was no left recurrent laryngeal nerve paralysis. The pupils were equal. The mind was clear.

November 2, a small trocar was inserted in the chest, through the fifth interspace, one and a half inches to the left of the sternum, and 1260 c.c. of brownish, slightly turbid fluid was withdrawn. This fluid contained a large amount of albumin. The specific gravity was 1020. Microscopically, there was found many red cells, a few polymorphonuclear leucocytes and large granular flat cells. Stained cover slips showed groups of short, thick, evenly-stained bacilli. Cultures revealed a pure growth of colon bacilli. Careful tests were made to differentiate from typhoid bacilli.

After the tapping, the patient expressed relief from a suffocative feeling which had been oppressing him for a few days. After tapping, it was noted that the bulging of the chest was less and the dulness somewhat decreased, although dulness still extended above to the first rib, five and a half inches beyond the left nipple and to the right border of the sternum. The dulness decreased more on the right than on the left or above.

The pulsations of the heart could be felt over the whole precordia, but the exact point of the apex-beat could not be located. It was, however, apparently not outside the left nipple line. A loud to-and-fro friction rub could be heard plainly over the precordia, loudest at the base of the heart and along the sternum. Relative dulness remained about the same in the left infraclavicular and scapular regions and dry and moist râles could be heard. The radial pulse was stronger and the pulsus paradoxus had disappeared.

The temperature remained as last noted. The respirations were not diminished and soon after increased in frequency. A blood count made November 8 showed 5,200,000 red cells, 4200 white cells and 90 per cent. hemoglobin (Fleischl).

It was noted that the signs of a gradual increase of the fluid in the pericardium were returning, and on November 11, 1050 c.c. of fluid was again withdrawn. This was turbid and reddish, alkaline in reaction, specific gravity 1022, and contained much albumin, a few polymorphonuclear leucocytes and red cells. No bacteria were found in this fluid in stained specimens and culture media inoculated remained sterile.

The tapping again relieved the patient's dyspnea and the pulse became stronger. He complained from this time on of weakness, the appetite was gone, he was apathetic, and usually lay half asleep, often muttering incoherently. When roused the mind was clear. Fluid gradually accumulated again in the pericardium, bringing more subjective distress, especially dyspnea.

The urine now contained much albumin and many hyaline and granular casts. Edema of the legs increased and the face became puffy. Friction rub was heard over the right chest, behind and in front. Moist râles increased in the left upper lobe and became numerous in both lungs posteriorly. The patient died suddenly November 23, fifty-two days after admission. The clinical diagnosis was pericarditis with effusion, right pleuritis, hypostatic congestion of both lungs, and nephritis.

The postmortem revealed the pericardium greatly distended with a clear straw-colored fluid; pericardium greatly thickened and adherent posteriorly to both lungs; pericardiomediastinitis, the whole surface of visceral layer covered by numerous large villi and nodules. In addition there was: Hypertrophy of the heart atelectasis of the left upper lung; adhesive pleuritis on the right side, adhesive peritonitis about liver and diaphragm; passive hyperemia of liver and spleen; tuberculosis of peribronchial, peripancreatic, retroperitoneal mesenteric and mediastinal glands, and finally edema of lungs. This case was reported by Dr. H. Gideon Wells.[1]

Here the pericarditis was the result of direct extension of tuberculosis from the mediastinal glands. Clinically it was impossible to diagnose tuberculosis.

To Dr. Robert H. Babcock was assigned the subject of adherent pericarditis, and I shall therefore leave to abler hands the clinical aspects of that form of pericarditis. The foregoing illustrations of pericarditis of several varieties, etiologically considered, present clinically, as far as the heart and pericardium are concerned, practically the same signs and symptoms.

CARDINAL SIGNS.

The cases further illustrate the importance of the three cardinal signs of pericarditis, namely, 1, the pericardial friction rub, 2, the form or outline of the precordial dulness, and 3, the position of the apex-beat, especially in relation to the left border of the precordial dulness.

The pericardial friction rub is doubtless present in every case of pericarditis in some period of its course. It is practically the sole local sign in plastic pericarditis. It may not be recognized in pericarditis with effusion, although it is probably present in every case at any early stage of the disease, and in cases which recover after the disappearance of the effusion. It may be present, too, during the stage of effusion.

I shall not discuss its character or the means of differentiating it from endocardial or pleuritic murmurs.

1. The Pathology of Active Tuberculosis of the Pericardium, JOURNAL A. M. A., May 25, 1901, p. 1451, vol. xxxvi, No. 31.

This is fully discussed in many good text-books on medicine and diagnosis.

The form of the outline of dulness in pericardial effusion is also characteristic. The pear-shape outline with the base downward; the dulness, even in the early stage of effusion, in the fifth right interspace, close to the sternum, obliterating the resonant angle formed by the lung, heart and liver; the dulness over the sternum extending to or above the second rib, together with the outline of the left border dulness, all these are easily recognized and almost pathognomonic. It is true that a greatly enlarged heart, with all its chambers dilated from myocarditis, and a weak diffusible apex-beat may present an outline of dulness which so nearly resembles that of pericarditis with effusion that it may be impossible to differentiate between them, without puncture. The limits of this paper will not permit the discussion of many of the interesting points concerning the precordial dulness of cardiac, vascular, lung and pleural diseases, and especially as compared with pericarditis.

The location of the apex-beat in pericarditis with effusion is characteristic. When it is perceptible it will always be found that the left border of dulness is relatively far removed from it, as it is not in any other cardiac disease.

In large effusions it may be obscured and at other times the right ventricle may strike the chest wall in the region of the nipple, or undulatory waves may be seen as the only evidence of the heartbeat against the chest wall. However, it matters not how the apex beat or the impulse of some other part of the heart against the chest wall be ascertained, it will be found that the point of contact of the heart against the chest wall is always relatively far removed from the left border of precordial dulness, as compared with the relations of the apex-beat to the left border dulness in all other conditions.

OTHER SIGNS.

Some of the other signs of pericarditis have been named in the reported cases. They are as follows: The relatively rapid respiration and dyspnea; the signs of compression of the left lung, evinced by the left interscapular and subscapular dulness and bronchial breathing; the rapid heart action, the pulsus paradoxus, and the asymmetry in size of the pulse of the radials; the irregular type of temperature; the paralysis of the left recurrent laryngeal nerve; the unequal pupils; the disturbed mental state of the patient, and still other phenomena. These are not so characteristic as the three cardinal signs first named, but are important and significant when present.

Pericarditis is an easily recognized condition. Frequent careful systematic examination of the precordium should be made in all infectious diseases, and if this is done pericarditis will not escape one. The diagnosis will then be made during life and not at the postmortem table as is unfortunately now the case in at least 50 per cent. of the cases of pericarditis which autopsy reveals.

100 State Street.

Treatment of Eczema.—Spiegler recommends painting the patch with equal parts of caustic potash and distilled water for a minute at most, and then cauterizing with equal parts of nitrate of silver and distilled water. The dressing then applied can be left undisturbed until complete recovery. This method of treatment is applicable only to chronic, limited, circumscribed eczema with no signs of inflammation.—*Derm. Cbl.* from Kaposi's Festschrift.

THE PATHOLOGY AND PATHOGENESIS OF PERICARDITIS.*

JOSEPH McFARLAND, M.D.

Professor of Pathology and Bacteriology in the Medico-Chirurgical College of Philadelphia.

PHILADELPHIA.

The ancients supposed disease of the heart to be incompatible with life, the heart being the center of life. Galen, in the second century after Christ, observed pericarditis in the lower animals and inferred its occurrence in man. Before this knowledge had been gleaned, all peculiarities of the structure or appearance of the heart were supposed to denote attributes of character. Thus, Haller speaks of the "hairy hearts" of Leonidas, Lysander and Aristomenes, as indicative of great bravery, those "hairy hearts" undoubtedly being viscera covered with stringy fibrin.

ETIOLOGY.

The disease is now known to be of frequent occurrence. It is most common in adolescence and early adult life, between the ages of 15 and 30. It occurs in childhood and in infancy, and rarely in the fetus. It also occurs in late adult lif and sometimes in senility. Knopf saw pericarditis 10 times among 459 cases of diseases of childhood, occurring between 1 and 11 years of age.

It is more frequent in men than in women, probably because they are more exposed to its causes. Concerning the relative frequency authors vary. Barthez and Rilliet observed it in 21 men and 3 women. Bamberger gives the ratio as 38 to 25, and Sibson at 35 to 28. All classes of society are liable to the affection, and it is not known that occupation or social condition has any predisposing tendency toward it.

It is customary to divide the cases into two classes: 1. Primary or idiopathic; 2, secondary or metastatic.

1. As all cases depend upon infection, and so far as we know, all the lesions depend upon the local operation of infectious agents, idiopathic pericarditis signifies nothing more than that the infectious agents having entered the circulation through some undiscoverable lesion, have produced their first visible changes in the pericardium. Inasmuch as such an accident must be much less frequent than the entrance of bacteria through recognizable lesions, primary pericarditis is extremely rare. Most writers of experience report that they have seen one or two cases of primary pericarditis, but all agree that it is very rare. Bauer in von Ziemmsen's Handbook states that out of the 3000 autopsies which occur yearly in Munich, he sees only two or three cases of idiopathic pericarditis.

2. Secondary pericarditis, on the other hand, is not infrequent and is a common complication of the infectious diseases. It occurs chiefly by hematogenous metastasis, but may also result from lymphogenic metastasis from contiguous infectious processes, and from internal and external traumatisms.

Traumatism as a cause of pericarditis may be disposed of in a few words, as it is of importance only as it affords an avenue of entrance for micro-organisms, or produces conditions favorable to their colonization in the tissue. External punctured and incised wounds are harmless, if performed under aseptic conditions. Ordinary wounds of the pericardium, if infected, produce a localized form of inflammation, not analog-

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section.

ous to the usual forms. The extent and character of the lesions will, however, vary according to the nature of the infectious agent introduced.

Internal traumatic lesions are not uncommon. Foreign bodies in the esophagus and stomach may perforate the pericardium. Tuberculous vomica may rupture into it; abscesses of the spleen, liver, lung, heart wall, mediastinal glands, etc., may burrow into it. Empyemas sometimes form fistulous communications with it, and echinococcus cysts and aneuryisms of the aorta sometimes rupture into it. Abscesses and other morbid conditions of the mammary gland and skin sometimes descend and invade the pericardium. In all of these conditions the morbid anatomic picture will vary according to the circumstances of the case, none of them conforming to the descriptions later to be given of the true clinical pericarditis.

Lymphogenous metastasis may occur in many of the local contiguous affections mentioned in which no actual traumatic lesion exists. In this manner, disease of the mediastinum, pleura, etc., may occasion pericarditis.

Hematogenous metastasis is seen in nearly all of the infectious diseases, but especially in the following: 1, rheumatism; 2, pyemia; 3, septicemia; 4, pneumonia; 5, chorea; 6, endocarditis; 7, other acute infectious diseases; 8, tuberculosis; 9, scurvy; 10, blood diseases, and 11, malignant disease.

Rheumatism is more liable than any other of the infectious diseases to be succeeded by pericarditis. The percentage of cases given by various writers differs widely. Bauer attributes this to the variation in the characteristics of rheumatism as it occurs in different places. The highest percentage of cases is given by Williams, who thinks it is 75 per cent. The following table gives the percentages of various authors:

Williams, 75 per cent.; Leudet, 22; Bamberger, 30; Chambers and Thompson, 20 to 30; Bauer, 16 to 20; Ball and Sibson, 20; Wunderlich, 19; Duchus, 16; Latham, 5, and Teller, 4.7 per cent. The occurrence of pericarditis is rare in subacute rheumatism and is said not to occur in chronic rheumatism. It therefore is to be looked for in the acute forms, and in gonorrheal rheumatism. The disease is more liable to occur in the polyarticular forms than in the monoarticular forms, and it is said to be most frequent in those cases in which the inflammation wanders quickly from one joint to another. Pericarditis may be the first expression of rheumatic infection, preceding the articular symptoms, or it may succeed them. The usual time for its occurrence is between the 6th and 14th days.

Pyemia is frequently accompanied by pericarditis, the relations of the two processes being so clear that no further mention of it need be made.

Septicemia is also frequently complicated by pericarditis. The statistics of Kirke and Willigk showing 5 out of 91 cases.

Pneumonia is liable to be accompanied by pericarditis in something over 7 per cent. of the cases. Leudet saw it 6 times in 83 cases.

Chorea is not infrequently complicated by pericarditis, Roger having observed it in 5 out of 71 cases, and Olivier in 1 out of 30 cases.

Endocarditis is quite frequently complicated with it. This is both because the two conditions are liable to depend upon the same cause, and because of the likelihood of metastatic infections in endocarditis.

Various other infectious diseases in which the occurrence of pericarditis does not take place with any regularity must also be mentioned. Among these are scarlet fever, smallpox, relapsing fever, measles, erysipelas, gonorrhea, syphilis, dysentery, cholera, typhoid fever, vaccinia, cerebro-spinal meningitis and diphtheria.

Tuberculosis may lead to pericarditis both by metastasis, continuity of tissue, and the rupture of vomica into the cavity. The lesions occasioned may be either local or general, and the exudation is nearly always purulent. Indeed, Birsch-Hirschfeld states that the majority of cases of pericarditis with chronic purulent exudation are tuberculous.

Scurvy is usually associated with hemorrhagic extravasations into the tissue and upon the serous membranes, and is nearly always accompanied by superficial lesions of the mouth and skin, which favor the entrance of bacteria into the circulation. Both of these conditions, together with the general vital depression that exists in scurvy, favor the development of pericardial infections, so that pericarditis with sero-sanguinolent, and purulent exudates are common. The effusions that can occur under these conditions may be enormous. Sometimes, in scurvy, pericarditis may be endemic and Koch is satisfied that it is identical with the *morbus cardiacus* of the ancients.

Blood diseases with diminished vital resistance, such as hemophilia, hemorrhagic diathesis, purpura, leukemia, diabetes, etc., may also be complicated with pericarditis. For the same reason the disease also occurs in alcoholism, cirrhosis of the liver and in nephritis. It is in chronic nephritis that pericarditis is most apt to occur, its development usually coinciding with the first symptoms of uremic blood poisoning. The frequency of its appearance is given by Taylor as 33 per cent.; by Bamberger, 14; by Rosenstein, 7, and by Frerichs, 4.5 per cent.

Malignant disease, as in carcinomatous invasion of the pericardium from primary disease of the mammary gland, esophagus, thyroid gland, etc., may by invasion of the pericardium lead to the diminution of its vital resistance, the occurrence of an unusual quantity of sero-sanguinolent exudation, and so predispose to the occurrence of infections, should bacteria in any way reach the tissues.

BACTERIOLOGY.

There is no specific micro-organism of pericarditis. The manifold conditions in which the disease occurs, and the varied morbid anatomic appearances which it presents, suggested this before experimental research in bacteriology proved it.

In the sero-fibrinous form of the disease, the study of numerous cases has revealed the presence of streptococci, staphylococci, pneumococci, bacillus pyocyaneus, the bacillus of Friedländer, and the bacillus tuberculosis.

In the purulent form, streptococci, staphylococci, bacillus coli communis, bacillus of Friedländer, and the tubercle bacillus have been found.

The hemorrhagic form is apt to be tubercuious, so that the tubercle bacillus may be found, together with other accidental organisms.

In the pyo-pneumo-pericarditis, and in fetid pericarditis, with communications with the lung, esophagus, etc., numerous saprophytic micro-organisms may be found.

MORBID ANATOMY.

It is customary to divide pericarditis into numerous forms according to the peculiarities of the exudate. The forms usually described being as follows:

1, Pericarditis sicca; 2, sero-fibrinosa; 3, purulenta;

4, adhesiva chronica; 5, hemorrhagica, and 6, tuberculosa.

Concerning the frequency of occurrence, the best figures obtainable seem to be those of Breitung, who collected 324 cases of pericarditis among the autopsies of the Berlin Charité, between the years 1866 and 1876, and found the following distribution:

Pericarditis sero-fibrinosa, 108; hemorrhagica, 30; purulenta, 24; tuberculosa deuteropathia, 24; tuberculosa idiopathia, 2; adhesiva partialis, 111; adhesiva totalis, 23, and ossificans, 2 cases.

It is an error to think of these names as referring to distinct forms of the disease. They are for the most part stages of the same process, and a description of the morbid process will make this clear. The first expression of the inflammatory process is found in redness and dryness of the surface of the pericardium—pericarditis sicca—upon which the vessels stand out with unusual distinctness. The natural glaze of the surface is lost, and the two surfaces, parietal and visceral, when they come in contact, rub one against the other with an unnatural degree of friction, which is painful to the patient, and which gives the well-known friction-sound to the ear of the auscultator. It may be that a few flakes of fibrin appear upon this dulled surface, and are rolled into threads by the incessant movements of the heart.

The disease may advance no further than this, and terminate in perfect recovery, but usually the excitant by which the disease is produced occasions further changes, and the inflammatory hyperemia is succeeded by a period of transudation, in which in most cases a clear serous fluid is poured out into the sac. Almost immediately a deposition of fibrin takes place from the fluid upon the surface of the membranes, chiefly, however, upon the heart itself. It forms a more or less coherent membrane which can readily be stripped off, leaving a fairly healthy surface behind. The membrane is, however, almost immediately changed in appearance by the movements of the heart, which tend to gather the sticky material into irregular forms. Upon the right ventricle, and especially upon its inferior and right surfaces, and upon the right auricle, the combined pressure and movement of the heart roll up the fibrin into threads of rounded form, which, after a time, give that part of the organ a shaggy, villous appearance—*cor villosum*. The left ventricle which has a different movement, and is freer of pressure, usually presents a reticulated membrane which is not unlike a piece of omentum upon its surface. As the accumulation of serum and precipitation of fibrin go on, the pericardial sac becomes distended, its base being broad, the precordial area tending to bulge it. The quantity of accumulated exudate usually reaches one-half to one pint, but it is not rare for it to reach a quart. Corvisart and Louis mention cases with exudates of 1000 and 1200 grams. Montague found one with 1850 grams of exudate, of which he withdrew 1000 grams by puncture. Gosselin once saw 2000 c.c. of fluid in the pericardium. The largest serous accumulation that I have seen recorded is that of Corvisart, who found 8 pounds of serum in one case.

If the bacteria upon whose activity the pericarditis depends are of markedly chemotactic influence, the exudate may be more or less purulent from the start. How often this is the case it is difficult to conclude from the number subsequently found to be purulent, and it is usually supposed that it is not uncommon for the sero-fibrinous exudate to become purulent in consequence of further changes in the local conditions. In 39 cases studied by Louis, the exudates were: Serous, 9; purulent, 7; sero-sanguinolent, 10, and sero-purulent, 13.

The purulent exudates are apt to be larger than the sero-fibrinous exudates. Martin has seen 3¼ pounds of purulent matter, and Alonzo Clark, 1 gallon of sero-pus in the pericardium. In cases of purulent exudation the pericardium is still found to be covered by the fibrin as previously described.

Should general conditions, such as the existence of scorbutus, or of local conditions, such as extremely active inflammation, exist, blood may be added to the exudate, whether previously serous or purulent. It is chiefly in scorbutus that bloody effusions occur, and it is almost inconceivable to what extent the pericardium may be distended. Andrea has seen 2 pounds of blood in the pericardial sac, and in scorbutic cases Kyber has found as much as 10 liters of bloody fluid.

The terminations of the process will depend upon its severity and the extent of damage done. When the disease does not advance beyond the stage of congestion, the return to the normal is a very simple matter. So soon as the membrane becomes covered with fibrin, however, new conditions present themselves and it is well-nigh impossible for recovery to take place without leaving marked changes behind.

The deposition of fibrin upon the already diseased surface is shortly succeeded by the degeneration and destruction of its covering endothelial cells. The connective tissue of the sub-endothelial layer of the pericardial membrane now begins to grow, and into the spaces of the fibrinous deposit a delicate, well-vascularized granulation tissue grows, extending as the fibrin melts away. Transmigrated leucocytes penetrate the tissues and aid in the removal of the fibrin.

The result of the presence of this growing tissue is that contiguous surfaces of the membrane are apt to grow together by firm fibrous unions, and that upon surfaces not in contact, more or less regular connective tissue indurations, and callous formations form. The length of time required for the formation of these adhesions is probably considerable. Their duration is permanent, though in the course of time the influence of traction may modify them.

While the absorption of the serum from sero-fibrinous exudates presents no great difficulties, the case is different when the exudate is purulent, for the burrowing tendency of the pus must be considered. Purulent exudations may be absorbed. They may, however, burrow in various directions and discharge externally. The usual seat of pointing is the precordium. Fabricius saw a purulent pericarditis point in the 2d left intercostal space. Wyss saw the pus penetrate a rib and be discharged externally. Rich reports a case that bored through the sternum and presented as a subcutaneous enlargement the size of an apple on the anterior chest wall. Sometimes the pus burrows down the back simulating the descending abscesses of Pott's disease; rarely it points sub-phrenically. One of the interesting terminations is into the lung, the pus being discharged through the bronchial tubes. This occasions what is known as a pneumo-pericarditis or a pyo-pneumo-pericarditis. In these cases, not only is the pus discharged into the bronchial tubes, but there is an opportunity for the purulent effusion in the pericardium to receive saprophytic bacteria from the lung and become fetid.

The purulent inflammation also leads to great thicken-

ing of the membrane. Horn has reported an interesting case of extraordinarily thick pericardium and Nunier has seen the membrane thickened and callous, with imbricated scales like a pineapple.

After evacuation of the pus there is usually some residual exudate, and in cases which terminate by resorption, the residuum is prone to undergo calcification. A most interesting case is reported by Drummond in which there was an extensive bone-like deposit between the layers of the muscular tissues of the heart—"a thick bone-like mass ran across the whole left ventricle, penetrating the entire wall of the heart like a wedge and reaching into the cavity of the left ventricle." Variot observed a case in which the left ventricle was covered by a solid hard plate of chalky matter on its whole anterior surface. Other cases of calcification have been observed by Tiessier and Richards.

PROGNOSIS.

The effect of pericarditis upon the heart is of great importance. No considerable disease of the epicardium is possible without involvement of the heart. The superficial layers of muscular fibers usually show cloudy swelling, later hyaline or fatty degeneration. In cases with purulent exudate the pus may also gradually work its way between the muscular bundles.

The changes that thus take place during the height of the disease predispose to acute dilatation of the heart, and a fatal termination of the disease may thus be brought about. If this does not occur, and if the patient recovers from the pericarditis, the regenerative cicatricial processes that go on lead to fibroid interstitial changes in the wall of the heart. If many adhesions form and interfere with the action of the heart, a very marked hypertrophy of the organ may occur to compensate for the embarrassment.

The tuberculous disease of the pericardium differs from the form described in that it is essentially chronic and purulent from the beginning. A proper description of the various pictures presented by this disease is made impossible by the time allotted to this paper.

Syphilitic pericarditis has been observed by Orth and by Lancereux, who observed gummatous formations in the pericardia of syphilitic children.

ETIOLOGY OF PERICARDITIS.*

ROBERT B. PREBLE, A.B., M.D.
PROFESSOR OF MEDICINE, NORTHWESTERN UNIVERSITY.
CHICAGO.

The etiology of pericarditis has been discussed so often and by so many that it is indeed difficult to present a discussion of it to a body of this character in such a manner as to arouse interest. For this reason it seemed better to disregard the extensive literature upon this subject and utilize the reports of three hundred cases as a text, dwelling upon some points of interest presented by them and drawing attention to some things in which they differ from generally accepted statements. The cases in hand consist of 80 cases ending in recovery and 220 ending in death, of which 190 were examined postmortem; 244 of these cases are acute pericarditis and 56 are of the chronic form with partial or complete obliteration of the pericardial sac. The cases are derived in part from the records of the Cook County Hospital, where many of the cases were seen personally and in part from private records.

The immediate exciting cause of the pericardial inflammation is usually unknown and apparently undiscoverable by our present methods. We know that there are certain diseases in which pericarditis frequently occurs as a complication, but whether the irritant causing the inflammation is a bacterium or a toxin is still uncertain. For example, the pericarditis accompanying the chronic diffuse nephritis may be of toxic origin; some authors, indeed, speak of it as a uremic pericarditis, or it may be of bacterial origin as others believe. So also the pericarditis of rheumatism may be due to a bacterium, or may be as some suspect the joint inflammations to be, of toxic origin. In a limited number of cases bacteria have been found in the exudate, pus cocci, pneumococci, tubercle bacilli, bacillus pyocyaneus and others, but in many cases the exudate is sterile. In many cases the irritant body reaches the pericardium through the lymph channels, or by direct extension, but doubtless there are numerous cases, apparently of this sort, which are really hematogenous.

It has been customary to divide the cases of pericarditis into two groups, primary and secondary, meaning by the former cases in which there is no manifest disease, to which the pericarditis appears as a complication. Most authors state that careful attention to etiology has reduced the primary cases to a vanishingly small group. This is doubtless true, but there is no apparent reason why the pericardium should so differ from other serous membranes that it does not become the seat of a primary inflammation. Of the cases which went to autopsy there is but one which could in any way be regarded as a primary pericarditis, and even in this case there was an old adhesive pleuritis, which might easily have been tubercular or the remains of a former pneumonia. This fact might be regarded as strong evidence against the existence of a primary pericarditis. There are 12 cases with 3 deaths in which the diagnosis of pericarditis alone is made. It is impossible to say how many of these cases should be regarded as examples of primary pericarditis, but in all the pericarditis was the prominent clinical feature and in several careful search for some cause failed to reveal any. Although there are no examples of pericarditis following injury of the pericardium in this series, such cases occur and in them the relation of cause and effect is too manifest to require any discussion.

Let us first take up the 244 cases of acute pericarditis or rather the 232 cases left after deducting the 12 cases already mentioned, grouped according to the primary disease and in the order of relative frequency.

First come 79 cases of pericarditis with acute pneumonia of which 73, i. e., 92.4 per cent. ended fatally. In 55 of them it is stated what lobes were involved in the pneumonia. In 23 cases the pneumonia was in the right lung, 21 in the left, and 11 times both lungs were involved. The percentages do not differ very greatly from those given by Aufrecht, Grisolle and Huss as to the relative frequency of the right, left and bilateral pneumonia, as shown in the following table:

	AUFRECHT, GRISOLLE, HUSS. Per cent.	PERSONAL. Per cent.
Right-sided pneumonia	52.0	23 cases, i. e., 42
Left-sided pneumonia	35.2	21 cases, i. e., 38
Bilateral pneumonia	12.8	11 cases, i. e., 20

* Read in a Symposium on Pericarditis at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee of the Section.

The right-sided pneumonia is complicated less often and the bilateral pneumonia more often than should be expected. More detailed consideration derives some interesting facts. According to Juergensen's figures, pneumonia is limited to one lobe in 65.75 per cent. of the cases, but in this series there are only 20 monolobar pneumonia, i. e., 36 per cent., which is approximately but one-half the normal number; there are 22 bilobar cases, i. e., 40 per cent., nearly twice the percentage given by Juergensen, 22.35 per cent.; there are 9 cases with 3 lobes involved, 16 per cent. as compared with 8 per cent., and 4 cases with 4 lobes involved 8 per cent. as compared with less than 2 per cent. The danger of pericarditis developing as a complication of pneumonia increases with the extent of the pneumonia and is relatively greater with left than with right-sided pneumonia. The various lobes are involved in about the normal percentages. In the 55 cases there were 107 lobes involved and the percentages correspond very closely to those of Juergensen as nearly as his figures can be utilized.

The following table shows this clearly:

	JUERGENSEN.	THIS SERIES.
Right lower	...29 per cent	25.23 per cent.
Right middle	...14 per cent.	14.94 per cent.
Right upper	....18.7 per cent.	16.82 per cent.
Left lower	.....25.4 per cent.	26.16 per cent.
Left upper	.....12.3 per cent.	16.82 per cent.

The most marked exception to the rule occurs in cases in which the right upper lobe alone is involved. Normally these cases make up 12.15 per cent. of the whole, but to this series they contribute but 2 per cent. This may be looked upon as compensation for the greater danger of cerebral complications which characterizes the R.U.L. pneumonia. Another important exception is the pneumonia of the entire left lung, which normally occurs in but 8.54 per cent. of all cases, but in this series makes 22 per cent. of the total.

When only a single lobe is involved, the especially dangerous lobes are the right middle and the left upper. The right middle furnishes 5 per cent. of the unilobar pneumonia complicated by pericarditis and only 1.77 per cent. of all pneumonia, the left upper 20 per cent. and 6.96 per cent. respectively. The most probable explanation of this is that the pericarditis results from direct extension from these lobes, both of which lie in closest anatomical relation to the heart.

The frequency with which pneumonia is complicated by pericarditis can not be definitely stated, for the statistics vary from a fraction of 1 per cent. to 8 or more per cent. Probably the figure given by Chvostek, 5 per cent., is about right, i. e., about 1 pneumonia in 20 is complicated by pericarditis. Utilizing the figures derived from this series of cases, we may say that with one-lobed pneumonia the chances of complicating pericarditis is 1 in 40; with two-lobed pneumonia, 1 in 10; with three-lobed pneumonia, 1 in 10; with four-lobed pneumonia, 1 in 5; with pneumonia of entire left lung, 1 in 8.

Next in point of frequency come the cases which present clinically an acute articular rheumatism or the effects of such an attack in an endocarditis. These cases number 65, of which 37 are accompanied by inflammatory changes in the joints with or without endocarditis and 28 are free of articular changes, but show old changes in the endocardium and fresh changes in the pericardium.

The most marked contrast between these cases and the pericarditis complicating pneumonia is the mortality. Seventy-three of 79 cases of pneumonia with pericarditis ended fatally, while in this group there are fifteen deaths and most of these were due to endocarditis or cardiac insufficiency.

Let us consider first the 37 cases presenting acute joint changes, of which 11 showed also an endocarditis. This is in rather marked contrast to the figures of Sibson, who has an elaborate paper upon pericarditis in Reynold's "System of Medicine." Sibson had 63 cases of pericarditis, of which 54 presented endocardial changes also. This is a much higher percentage than these cases give even if we take all 65 cases together yielding 39 cases of endocarditis. This is probably due to the fact that these cases are nearly all adults and the bulk of them males. The same rule holds for pericarditis and endocarditis, the danger of these complications is greatest during the first two decades of life; the younger the patient, the greater the danger of cardiac complications. Sibson found that one-half of the male and more than one-half of the females were under 20.

Sturges, in 100 fatal cases of heart disease in children, found 54 of rheumatic origin and all but 6 of these showed also a pericarditis.

In this series there are 56 males and 9 females, which would indicate a very great predisposition on the part of male patients. This inference can not, however, be made, because of the very great excess of male patients in the hospital. Sibson, however, finds in his series of 35 males and 28 females, which is in proportion to the number of cases of acute articular rheumatism as 1 to 4 and 1 to 6 respectively, and finds that beyond 21, males are attacked three times as often as the females. These figures differ from those of the Commission of the British Medical Association, which examined the reports of 655 cases of acute articular rheumatism, in 111 of which there was a pericarditis, 56 males and 55 females.

There is no invariable relation between the number of joints involved or the severity of the changes, but in general the more numerous and the more severe the joint changes, the greater the danger of pericarditis developing.

Sibson, Ball, Wunderlich, Leudet, all place the percentage of cases of acute articular rheumatism developing pericarditis at 20 per cent., the British Commission at 16.94 per cent., Bamberger and Eichhorst place it at 14 per cent. and Latham as low as 7 per cent. With few exceptions, of which Stokes, Graves, West, Trousseau and others have reported examples, the joint changes precede the pericarditis by about 10 days to 2 weeks; 6 to 10 days (Hughes), 14 days (Bamberger), 11 days (Sibson).

Chronic rheumatism and gonorrheal rheumatism rarely excite pericarditis, but examples of both have been recorded by various authors.

Of the 65 cases of pericarditis of rheumatic origin, 39—i. e., 60 per cent.—were accompanied by endocarditis, a figure somewhat lower than that of Sibson, who found the combination in 54 of 63 cases—i. e., 85.7 per cent. This is from 3 to 4 times the normal percentage of endocarditis—namely, 20 per cent. Of the cases in which the endocardial lesion is specified, two-thirds are of a single valve and one-third combined aortic and mitral. This is the normal relative frequency of univalvular and bivalvular endocarditis. Of the single valve lesions, the mitral are three times as common as the aortic. A case of combined rheumatism and endocarditis is very apt to be further complicated by a peri-

carditis, but this danger is no greater for aortic than for mitral endocarditis.

The third group, consisting of 26 cases, is made up of pericarditis developing in the course of a nephritis. The frequency with which this complication occurs is variously stated by various authors, Rayer putting it as low as .5 per cent. and Buhl as high as 35 per cent. Probably the correct figure is about 15 per cent.; this is the figure obtained by Meier from 321 autopsies on patients with nephritis. Sibson puts the figure at 8.4 per cent. for England, 10.4 per cent. for Germany and 3 per cent. for France. While it may occur with any form of nephritis, it is particularly apt to occur with the chronic diffuse nephritis with contractions. This is the form of nephritis in all of these cases. Sibson states that he found pericarditis twice in 15 cases of acute Bright's disease not following scarlet fever, and no cases with the nephritis following scarlet fever; once in 62 cases of large white kidney; 23 times in 162 cases of granular kidney; twice in 22 cases of amyloid kidney. It has been justly regarded as a serious complication as is shown by the fact that 22 of this series ended fatally, 21 being examined postmortem.

The explanation of the relation of pericarditis and nephritis has been a matter of dispute ever since the relation was noted by Bright in 1827. Theoretically, we can imagine three possible relations, 1, an acute infection exciting both pericarditis and nephritis; 2, an acute infection in a nephritic, exciting a pericarditis, and 3, pericarditis developing in a nephritic patient without any manifest cause except the nephritis. This last group is the one which concerns us and all of the 25 cases belong here.

The older writers, like Bright, Traube, Wagner, Bartels, believed that the pericarditis was of toxic origin and excited by the altered state of the blood. Kéraval tried to excite pericarditis by injection of urea, carbonate of ammonia and the like into the pericardial sac of healthy animals, but failed to obtain any results. He, however, retained the opinion that the pericarditis was of toxic origin. More recently Beco produced slight pericarditis in 3 rabbits, and marked in 1, by ligating the ureters. He does not, however, think that this proves the uremic origin of the pericarditis. Still more recently Chatin examined the pericardial fluid and the toxicity of the blood serum in four cases, and in all found the fluid sterile and the toxicity of the serum low.

Lécorché and Talamon, noting the frequent association of the pericarditis with inflammation of the lungs, pleura or endocardium, thought the pericarditis an infection. With the exception of one case by Bosc, in which the pneumococcus was found, the fluid has been found sterile, four times each by Banti and Chatin, once each by Beco, Merklen and Dessy.

The next group is the tubercular group, consisting of 24 cases, all ending in death, and 20 subjected to autopsy. In 6 of these the pericarditis is a part of an acute miliary tuberculosis; of the other 14 cases the lungs were the seat of a chronic tuberculosis in all. Three times empyema, once right and twice left, was present. Many of the cases showed also a chronic inflammation of the pleura, in a few the bronchial, mediastinal and mesenteric glands were involved. Of the four cases not examined postmortem one was a tubercular pneumonia, two were combined tuberculosis of pericardium and pleura, one was a tuberculosis of lung, pleura, pericardium and peritoneum.

There are 11 cases grouped as sepsis, 10 of known origin and 1 kryptogenetic, all ending fatally. In 5 cases the original infection is remote from the pericardium, twice an osteomyelitis and three times a cellulitis. In 5 cases direct extension may be assumed, once from a right-sided pyo-pneumothorax with gangrene of the lung, once from a subphrenic abscess secondary to a carcinoma of the stomach, twice from suppurative mediastinitis and once empyema probably of pneumonic origin.

Then come six cases of aneurysms of the ascending or transverse aorta, four with acute pericarditis and two with rupture of the aneurysm into the pericardial sac. There are four cases of typhoid associated with pericarditis, three ending in death and autopsy and one recovering. Lastly, there are seven cases in which tuberculosis, pleuritis, endocarditis, myocarditis, aneurysm and nephritis are so combined as to make it uncertain which factor is most important in determining the pericarditis.

There are 56 fatal cases of chronic pericarditis, all with autopsies, and in 37 of them one can infer the cause with a fair degree of certainty. The uncertainty of the clinical diagnosis of adherent pericardium has led to the exclusion of all purely clinical cases. Cases in which a positive clinical diagnosis of concretio cordis can be made are so few that they may be neglected for purposes of this sort. Of the 37 cases in which the cause seems clear 19 are found associated with chronic diffuse endocarditis, 11 with tuberculosis, 5 with chronic diffuse nephritis and 2 with aneurysm of the aorta.

Of the 19 cases associated with endocarditis, which in all cases was chronic, although in a few there was an acute exacerbation, 10 were upon both the aortic and mitral valves, 5 on the mitral alone, 3 on the aortic valves alone and 1 on the mitral and tricuspid. These figures are of interest when one recalls the figures as to the relative frequency of the various valvular lesions given by Sperling from the Virchow Institute. According to these combined aortic and mitral lesions make up but one-quarter of the entire number, yet in more than one-half of the 19 cases of combined endocarditis and obliterative pericarditis, the endocardial lesion was double. The danger of pericarditis is six times as great with a mitral and aortic endocarditis as with either lesion singly. I believe this fact can be utilized in the clinical diagnosis of concretio cordis. Obliterative pericarditis was found three times with simple aortic endocarditis and five times with simple mitral, i. e., 3 to 5, a relatively high figure, for normally simple mitral is four times as common as simple aortic endocarditis. The danger of pericarditis is proportionate to the extent of the endocarditis, and aortic endocarditis is more often accompanied by pericarditis than is mitral endocarditis. This differs somewhat from the cases of acute pericarditis where it did not seem to make any difference whether the endocarditis was aortic or mitral.

All of the 11 cases of obliterative pericarditis associated with tuberculosis showed a chronic tuberculosis of the lungs; most of them showed in addition an obliterative pleuritis either unilateral or bilateral, and in a few instances there are tubercular foci elsewhere in the body. Three of the cases showed also an acute diffuse miliary tuberculosis. It is manifest from this that tuberculosis is by no means so potent a factor in the production of the obliterative pericarditis as has been generally stated. When one recalls the very large num-

ber of patients suffering from pulmonary tuberculosis these few cases appear very insignificant. Sepsis, especially the attenuated form known as acute articular rheumatism, when accompanied by endocarditis, is a much more potent factor.

There are four examples of concretio cordis accompanied by nephritis. In none of these is there any manifest cause of the pericarditis except the nephritis, and while it is generally stated and generally true that pericarditis accompanying nephritis is an advance courier of death, this is not always so, as was illustrated when speaking of the acute pericarditis, and we must assume the nephritis as the cause in these cases. It is, of course, possible that the concretio cordis came from some other cause and the nephritis is superimposed.

In two instances the obliterative pericarditis was associated with an aneurysm of the aorta. In 19 cases the process which excited the old pericarditis could not be determined at all, or at least not with certainty. In 9 of the cases the immediate cause of death was an acute croupous pneumonia, and neither history nor autopsy cleared up the questionable cause of the pericarditis. In four cases the death was due to cardiac insufficiency. In the other cases endocarditis, tuberculosis and chronic nephritis were combined in various ways, and in such manner as to prevent any safe guess as to which, if either, caused the pericarditis. The most noteworthy fact in these cases is the large number of deaths caused by pneumonia—9 out of 19.

CONCLUSIONS.

1. Cases of acute pericarditis clinically primary occur, but are rare.

2. Diseases to which pericarditis appears as a complication are in order of their frequency; pneumonia, 34 per cent.; rheumatism, 28.36 per cent.; chronic diffuse nephritis, 11.2 per cent.; tuberculosis, 10 per cent.; sepsis, 4.7 per cent.; aneurysm, 2.6 per cent.; typhoid, 1.7 per cent.

3. The more extensive a pneumonia the greater the danger of this complication.

4. The danger is somewhat greater with left than with right-sided pneumonia.

5. Where only one lobe is involved the danger is least with a right upper-lobed pneumonia, and greatest with a right middle or left upper-lobed pneumonia.

6. With a unilobar pneumonia the chances of a pericarditis are 1 in 40; with a bilobar or trilobar, 1 in 10; with a quadrilobar, 1 in 5, and with a pneumonia of the entire left lung, 1 in 8.

7. The mortality of pneumonia with pericarditis is 92.4 per cent.

8. Rheumatic pericarditis is complicated by endocarditis in 60 per cent. of the cases, i. e., three to four times the normal rate of cases of endocarditis.

9. The danger of pericarditis complicating rheumatism is the greater the younger the individual, and is somewhat greater with males than with females.

10. So far as acute pericarditis is concerned, the site and extent of the endocarditis is apparently of no importance.

11. Pericarditis appears as a complication of all forms of nephritis, but particularly the chronic diffuse nephritis with contraction.

12. It is an extremely ominous thing, for 22, i. e., 84.6 per cent. of the cases died.

13. It is still uncertain whether the pericarditis is toxic or infectious.

14. Tuberculosis excites only one-tenth of the cases, and when one considers the extreme frequency of tuberculosis, pericarditis must be regarded as a rare complication.

15. Pericarditis may be a part of a generalized acute tuberculosis, but is more often the result of a chronic tuberculosis of the lungs or mediastinal glands.

16. Septicemia and pyemia contribute a very considerable number of cases of pericarditis. The primary focus may be remote or close to the pericardium.

17. Aneurysm of the aorta causes 2.6 per cent. of all the cases, a very high figure when one recalls the comparative infrequency of aneurysm.

18. Typhoid fever, which is rarely complicated by inflammation of the serous membranes, other than the peritoneum, contributed 4 cases, which is 1.7 per cent.

19. The cases of obliteration of the pericardium are due to the following causes arranged in order of importance; endocarditis, tuberculosis, chronic nephritis, aneurysm.

20. More than one-half of the cases, in which the cause was clear, were due to endocarditis, or rather to some cause common to both the endocarditis and the pericarditis, and more than one-half of these cases showed a combined aortic and mitral endocarditis.

21. Relatively six times as many cases of obliteration of the pericardium occur with aortic and mitral endocarditis than with either lesion singly.

22. Tuberculosis causes but few cases of obliterative pericarditis.

23. Pericarditis, accompanying nephritis, is not always fatal, but may apparently end in the formation of adhesions.

[Remainder of papers in the Symposium, with the discussion, will follow next week.]

THE EXTRACTION OF CATARACT WITHOUT IRIDECTOMY.*

S. D. RISLEY, M.D.
PHILADELPHIA.

Until very recently I have performed all extractions of cataract by the combined method, that is to say, with iridectomy, and in a considerable percentage of cases the iridectomy was performed as a preliminary operation from four to six weeks before the extraction was undertaken. This plan was adopted for the reason that I believed the prognosis was better, especially with preliminary iridectomy. For the past few years, prompted by the favorable reports of other surgeons, I have done the simple extraction, but with a few exceptions only in selected cases. The grounds for selection were the absence of any noteworthy pathological history, or discoverable indication of pronounced uveal disease; a promptly reacting iris, a pupil which dilated readily to at least large medium under a mydriatic; and a lens with more or less well-defined sectors and without transparent anterior cortex, that is to say a ripe cataract. A long history of asthenopia, preceding the failure of vision from incipient and immature cataract, a more or less discolored iris, sluggish in its reaction to light and shade, and to mydriatics, white patches on the lens capsule, a dark or brownish lens, injected conjunctiva and swollen caruncles associated with headache, and a protracted ripening of the cataract, furnished a group

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

of conditions which excluded the case from any attempt at simple extraction. Many of the excluded cases came under observation in their early history when it was still possible to study the existing intraocular conditions in one or both eyes. Chorioidal disease associated with vitreous degeneration was frequently found. The degeneration of the lens in this group of cases usually began with a granular, outlined nucleus and disease at the posterior pole, probably of the posterior capsule, to be followed by peripheral spicules and the tardy ripening or opacification of the entire lens; or the anterior cortex remained for an indefinite period translucent and became amber colored. The participation of the uveal tract in this chronic disease process was indicated by the sluggish iris which did not respond fully to the mydriatic and by a chronic dilatation of the anterior perforating ciliary vessels. To attempt to dislodge the lens from the diseased posterior capsule, to force it through the small pupil of an inelastic iris, prone at best to inflammatory reaction from its association with the general uveal disease, thus causing an inevitable traumatism, was regarded as unwise surgery. The compound operation, often with preliminary iridectomy, was therefore adopted in the group of cases more or less accurately described in the foregoing remarks.

TECHNIQUE OF SIMPLE EXTRACTION.

Even in favorable cases the technique of simple extraction is of signal importance. With rare exceptions where the result has been in any respect disappointing it could be traced to wanting docility upon the part of the patient or to a fault on my own part in some detail of the operation. I have not always found it possible to accurately carry out in all its details my own conception of the rigid mechanical and mathematical requirements of a perfect technique. A variety of circumstances are lurking unseen to trip the most wary. A most carefully selected knife for some unaccountable reason proves faulty and disappointing at the critical moment; the slightest change in the location of the cornea in relation to the source of light presents annoying reflexes and adds materially to the deceptive conditions due to the optical or refraction effects of the curved surface of the cornea, and as a result the counter puncture is not exactly as designed; any too vigorous effort to correct the position of the eye by means of the fixation forceps may distort a readily yielding globe, not only producing changed optical conditions in the cornea, which may be deceptive as to the exact location of the knife, but causing the iris to fall in front of its edge. When the possible action of the patient is added to these it is obvious that the realization of a perfectly correct technique is not always obtainable.

The knife I prefer is ground hollow, 2 mm. wide and 28 to 30 mm. long, and I carefully select one with a point not so finely drawn as to be invisible when held before the dark surface of the iris. A too fine point is often responsible for the faulty counter puncture. The puncture and counter puncture are made exactly at the clear limbus, the width of the knife blade above the horizontal meridian of the cornea. The section is then carried upward without deviation to the upper border of the cornea where it is made to dip slightly backward to secure a conjunctival flap. The section is made while the lids are held apart with a soft spring speculum, the eye being fixed with toothed forceps grasping the conjunctiva and subconjunctival tissue at the lower end of the vertical meridian of the cornea near the limbus. An anchor or T-shaped capsulotomy is then made and the speculum removed. The upper lid is raised by an assistant either with the finger or an elevator; the posterior lip of the wound is supported firmly by a horn spatula and the lens caused to present by pressure with the finger below, exerted through the lower lid, which is made to follow the escaping lens with a to and fro movement to secure the escape of any tardy remnants of cortex which may be scraped off by passing through the pupil and wound. No effort is made to immediately replace the prolapsed iris except by a gentle stream of warm sterile physiological salt solution from a fine pointed pipette. If the iris does not return the lids are closed gently and a light rotary massage with the tip of the finger, exerted through the upper lid, and a moment's rest permitted. If any tendency to prolapse remains it will usually be found to be due either to a faulty corneal section, which is shown by a tendency of the wound to gape, or by the collection of fragments of cortex behind the iris, or possibly by a rupture of the suspensory ligament above and the presentation of vitreous at that point behind the iris. In either of the last named conditions gentle pressure backward and downward upon the iris with the round surface of the spatula will often reduce the vitreous or cause the imprisoned fragments of lens cortex to present in the pupil.

In every case where subsequent prolapse of the iris actually occurred or when the tendency to prolapse was manifested by a distortion of the pupil and adhesion of the periphery of the iris to some portion of the wound during convalescence, the tendency was obvious at the time of the operation. Exceptions to this rule are furnished by one case in the following reports when the prolapse was produced on the fifth day, by straining in the attempt to urinate. The operations, with few exceptions, were made under cocain and usually with a dilatation of the pupil by atropia. A solution of salicylate of eserin was uniformly instilled after the last sterilization of the eye and immediately before the corneal section was made. The effect of this is to maintain for an hour or more the contraction of the pupil, and a lessening of the probability of prolapse during the most critical period of convalescence, after which the atropia dilatation is resumed. Irrigation of the anterior chamber for the purpose of washing away any remaining cortex was studiously avoided except in the earliest operations. I prefer to trust to the absorption of small flakes of cortex rather than risk the rupture of the suspensory ligament by protracted efforts for their removal by manipulation or the occurrence of striped keratitis from the irritation of the fluids used in washing out the anterior chamber.

AFTER TREATMENT.

If the iris did not promptly return after the delivery of the lens, or if the pupil manifested any tendency to distortion in the direction of the wound the dressings were not applied immediately. If the tendency to prolapse increased, a narrow iridectomy was made and the case classed with the compound operations. There was cause for regret in every case when this rule was neglected. After thorough irrigation with warm boracic acid or salt solution the conjunctival flap was carefully replaced, the lids of both eyes closed and fixed by strips of isinglass plaster, placed in the form of the letter X.; over these a moist square of gauze and a pad of cotton. This was in turn fastened by a strip of isinglass carried from temple to temple and a second strip placed diag-

onally from the center of the brow downward and outward to the cheek. A knit bandage with tapes was then applied over the eyes and while the tapes were held firmly at the temples by an assistant the ends were carried backward and forced between the pillow and occiput without raising the patient's head and tied in

Name, Age, Volume.	Operation Notes.	Convalescence.	Prolapse.	Remarks and Vision.
1, L. D., age 66 . .	10, 10, '92—Operation smooth.	Without incident. 11, 30, 92—secondary, leaving a large round, cent. p. 5, 15, '93—V. = 6/IX. +12 ⊃ + 1 C. 180°.	None . . .	3, 29, '97 - +14 S. V. = 6/VII 1/2.
2, N. Y., age 68. . .	11, 17, '99—Smooth upward section; then patient behaved badly. Lens extracted with loop; some loss of vit. and prolapse of iris.	11. 8—wound healed kindly. Ether administered on second day and prolapse excised and eye did well.	Prolapse excised on second day.	Notes incomplete: good vision.
3, E. A., age 75. Morganian Cat., xiii, 204; illiterate; blind fourteen years.	11, 5, '94—Lens escaped in capsule on completion of section and iris folded itself in upper angle of Ant. Ch., leaving a gibbous pupil, clear and black.	11, 7, '94—no reaction; pupil still gibbous. 11. 14—pupil changed to a flaring coloboma up as after a broad iridectomy. Conj. catarrh. 11, 21—tear duct washed out. 1, 14, '95—Iris is now unfolding itself from above and appears below upper limbus.	None; pupil ovoid.	1, 14, '95—V. = 6/IX.
4, J. C., age 59, Farmer.	10. 23, '99—smooth extraction, small conj. flap; eye closed with pupil slightly ovoid.	10, 25—eye quiet, no reaction. 10, 28—A. C. filled with blood clot and blood on dressings. No pain. Patient thinks he injured eye in the night. 11, 20—blood slowly absorbed, leaving gray capsule. Capsulotomy, leaving clear pupil. 11, 22—no reaction.	None	11, 24, '99—+10 ⊃ +3C. ax. 180°. V. = 6/VI.
5, M. A., age 66 . .	5, 29, '99 - conj. flap; iris punc. by knife point but disentangled and smooth section made; clear, black central pupil, slight distortion up and out.	No reaction until seventh day. Slight iritis with flushed eye and two synechiæ with strong band across, pupil oval. Capsulotomy with bent keratome. No reaction. 6, 30—capsulotomy.	None.	6, 30; +10 D. V. = 6/VI.
6, C. L., age 66, O. S.	5, 17, '99—operation smooth; conj. flap; clear black pupil, but ovoid, with tendency to prolapse; eserin instilled and light dressing; in an hr. pupil central and nearly round. Eye dressed as usual.	First dressing 16 hrs. after operation; no pain, no puffing of lids. Eye not opened. On 2d day eye opened and iris prolapsed into wound, filling entire section. Spec. introduced, eye washed. Cocain and broad iridectomy made, leaving clear wound and moderate coloboma. No reaction, eye healed without incident.	Prolapse on second day excised.	Much opaque cortex on 2d d.; prob. post. which prob. coll'ct'd behind iris, causing prolapse; 6, 19, capsulot'my; V. = 6/XII.
7, C. L., age 66, O. D.	11, 13, '99—conj. flap; opr. smooth; pupil clear and black, slightly ovid; upper rim drawn slightly upward, tending to prolapse.	Eye recovered without reaction, but upper margin of pupil drawn upward, but entangled in wound, which is smooth.	None, but pupil ovoid.	11, 30, '99; +10 ⊃ +2 C. ax. 170°. V. = 6/IX.
8, A. G., age 70; high grade imbecile.	10, 9, '99—ether anes.; conj. flap; profuse bleeding into A. C.; central round pupil.	No incident, but capsule gray.	None	12, '99; +10 ⊃ +2 C. ax. 90°, V. = 6/IX.
9, J. T., age 70. . .	3, 6, '99—Operation smooth; conj. flap; round, central pupil.	No reaction.	None	3, 15, '99; sees time on watch; 4, 19, '99, +2 ⊃ +3 C. ax. 165°. V. = 6/XII.
10, A. W., age 67. .	11, 28, '98—smooth extraction; pupil black, slight notch above.	No incident; some cortex in capsule above and below, clear black center.	None	V., no record.
11, S. R., age 58; coal worker.	11, 28, '99—operation smooth; central, round, clear pupil.	12, 9—eye white.	None	12, 9. '98; sees time on watch; 12, 16, '98, +8.50 ⊃ 5.50C. ax. 180°. V. = 6/VII—1/2.
12, L. C., age 65. . .	11, 4, '98—Operation smooth; large conj. flap. (Paralysis.)	11, 18, '98—eye healed without reaction, round central pupil; but on eighth day lost power over left arm, which spread to complete paralysis of left arm and leg. Sees time on watch.	None	P. round, black, reacting to light: sees time on watch; sent home without glass.
13, R. W., age 49. .	10, 10, '98—too small section; pupil central but slightly ovoid upward.	10, 14—eye red; much opaque cotex and gray membrane; 12, 12—secondary.	None	2, 23, '99; +10 ⊃ 5 C. ax. 25°. V. = 6/V.
14, A. H., age 74. .	12, 13, '97—conj. flap; smooth sect.; patient squeezed and ext. lens immediately after capsulotomy; clear black pupil; slt. tear in upper rim.	12. 17—some conj. injection and delicate adhesions to capsule; 12, 27—eye white.	None	V., no record.
15, M. B., age 60. .	11, 15, '97—Operation smooth; round, central pupil; clear.	11, 17—no reaction; 11, 24—gray membrane; 1. 3, '98—secondary.	None	1, 10, '98; +10 ⊃ +2 C. ax. 135°. V. = 6/VI.
16, T. W. K., age 60	Some loss of vitreous.	Periphery of iris adherent. Hemorrhage in A. C., oval pupil.	None	V. = 6/LX.
17, L. A. H., age 66; O. S.	Tough capsule; some cortex remains; 11, 1, '97.	Mild iritis with synechia on eighth day. Much opaque cortex; 1, 10, '98—capsulotomy.	None	1, 26, '98; +10 ⊃ +2 C. ax. 90°. V. = 6/VI.
18, A. R., age 49; eye had been injured.	11. 15, '97—small nick in extreme periphery of iris while making sec.; eye squeezed by patient, suddenly extruding lens after capsulotomy; round. central. black pupil; no tendency to prolapse.	11, 17—A. C. restored; eye not red; 11, 22—says he "banged" his eye in the night; small cyst of conj. above section; bandage; 11, 26—small synechia capsule; 1. 3, '98—capsulotomy; 1, 7—marked reaction and iritis; cold compresses.	None	4, 4, '98; +10 ⊃ + 2C. ax. 180°. V. = 6/IX.
19, G. H , age 50; O. S.	10, 18, '97—tough capsule; soft cortex; hard nucleus; cort. removed with spoon; round, cent., black p.	No incident; 11, '97—secondary; central pupil; 11, 8, '97 - +6 ⊃ +4 C. ax. 90°. V. = 6/XXX.	None	1, 12, '98; +10 ⊃ +2 C. ax. 180°. V. = 6/XII.
20, R. McN., age 68	3, 29, '97—large amount of soft cortex delivered with a spoon; some retained; bead of vitreous presented, but none lost; round, central pupil, upper half black.	4, 2—A. C. restored; eye too red; opaque cortex fills pupil; 4, 5—pain, gray point in cornea at inner angle of wound; later a gray membrane hung from this; conj. chemotic and c., but slowly subsided, leaving a slight pouting of wound at inner angle, pupil drawn toward it; iris tucked into angle but not prolapsed into wound as far as can be seen.	None	1, 14, '97; +10 ⊃ +2 C. ax. 150°. V. = 6/LX. 4, 19, '97; V. = 6/XX.
21, O. S., I. S., age 55; washerwoman	12, 14, '96—tough capsule; lens ext. in capsule with loop; no vit. lost.	12, 16—A. C. restored and eye quiet; stri. keratitis along border of section above; 4, 26—capsulotomy.	None	1, 14, '97; +10 ⊃ +2 C. ax. 150°. V. = 6/LX. 4, 19, '97; V. = 6/XX.
22, O. D., I. S., age 55	5, 31, '97 - extraction simple, no notes	Iritis, synechia, gray capsule	None	7, 16, '97; +13 = 6/XV. Capsulot'y advised; but did not return.
23, T. B , age —; O. S. Comp. ext., V. = 6/VI. Iris fell before K.	3, 22, '97—Operation smooth; central, round, clear pupil.	No incident; 4, 26. '97 - capsulotomy.	None	4, 30, '97; +9. V. = 6/IX.
24, O. D., P. C , age 51.	11, 16. '98—iris fell before knife at extreme periphery, making small opening; otherwise opr. smooth; large amt. wht. flocculent cortex.	No incident	None	11, 25, '98; +9 ⊃ 2 C. ax. 60°. V. = 6/XV. 1. 4, '97; +11 ⊃ +1 C. ax. 30°. V. = 6/XII.
25, J. McG., age —; O. S. fell before K. and made iridectomy.	10, 9, '96—lens found app. dislocated, when capsulotomy was attempted; ball soft, but lens presented by pressing on ball below and was delivered easily; clear, blk., cent., rd. pupil; no tendency to prolapse.	No incident; 11, 13, '96—capsulotomy	None	11, 23, '96; +10 ⊃ +1 C. ax. 180°. V. = 6/XII.
26, J. McD., O. D..	2. 3, '96—smooth extraction; central, round, clear pupil; counts fingers.	No incident until fifth day; some injection of conj., and on seventh day slight synechia to capsule.	None	2, 28, '96; +12. +1 C. ax. 115°. V. = 6/XII.
27, O. S., J. P. R., age 52.	11, 25, '95 - operation smooth; small rupture in upper rim of pupil by escaping lens; no tendency to prolapse; small. clear, central pupil; round, except small notch above.	Recovery without incident.	None	4, 5, '96; +10 ⊃ + 1 C. ax. 180°. 4, 29, '96; +11 ⊃ 1 C. ax. 15°. V. = 6/VI. 2, 6, '99; not poss. by ordinary observ. to tell operated eye. V. = 6/V.

Name, Age, Volume.	Operation Notes.	Convalescence.	Prolapse.	Remarks and Vision.
28, O, D., G. W. H., age 58; O. S., opr. on by Dr. Norris at Wills' Hosp. 4 yr. ago. V. = 6/XXI.	12, 16, '95—Smooth extraction; no incident; round, central pupil.	12, 30, '95—eye shows some conj. injection; no iritis Sees time on watch.	None	12, 30, '95; later V. = 6/VI. Returned in '97 with opaque cap. sule and reduced V. Secondary oper. fol- by panophthalmitis and loss of eye.
29, O. S., J. J. Connor, age 51.	11, 25, '95—smooth, round, clear central pupil.	Without incident; 3, 24, '97—capsulotomy. V. = 6/21. .	None	+11 = 6/VI,
30, Mr. Hart. . . .	Feb., '96—operation smooth; central, round, clear pupil.	Small hemorrhage on fifth day in A. C., but rapidly absorbed.	None	+13 ⊃ +1 C. ax. 10°. V. = 6/V.
31	Operation smooth; central, round pupil.	Catheter necessary; tried to escape it by getting out of bed on the fifth day; pain in eye while straining to urinate causing prolapse of iris.	Prolapse while straining to urinate 5th d.	V. = 6/XII.
32, O. S., Mrs. C. L. W., age 61.	5, 14, '00—smooth operation; clear, central, round pupil.	5, 16, '00—A. C. restored; 5, 21, '00—eye getting white; some adhesions between caps. and iris pupil; dilates irregularly.	None	6, 15, '00; +11 ⊃ +2.50 C. ax. 1. V. = 6/VII −1/2
33, A. O., age 68. .	11, 19, '00—opr. smooth, except upper rim of p. caught in removing cystotome; spec. removed; lens app. settled back, and in escaping was preceded by small amt. of very fluid vit, leaving part of lens at inner side p., deeply placed; eye closed, fearing greater loss of vitreous.	11, 20, '00—A. C. restored; 11, 23—eye doing well, no reaction, some swelling of conj. flap; outer half of pupil clear and black. 11, 26, '00—eye almost white, but much bulging of conj. flap and app. gaping of wound under it; pupil round; compress bandage; 1, 18, '01 cataractus mass slowly absorbing; 3, 15—cortex almost disappeared.	None	6, 15, '91; +11 ⊃ +2.50 C. ax. 10°. V. = 6/VII−1/2.
34, O. D., R. F., age 57.	11, 19, '00—smooth; lens extrac., leaving some soft cortex; patient turned eye strongly downward, rupturing the susp. and causing a gush of fluid vitreous; eye closed with round, central pupil.	11, 21—eye doing well; 11 23—some pain in night and morning; hemorrhage in A. C.; 11, 26—eye almost quiet; large, dark blood clot in lower angle of A. C.	None	1, 2, '01; +10.50 ⊃ +4 C. ax. 180°. V. = 6/V ?
35, Mrs. S. W., age 70.	11, 19, '00—smooth; conj. flap; anchor section in cap.; lens delivered, leaving much soft cortex, which was removed with spoon.	11, 26, '00—without incident; some pouting of conj.; white band in capsule; central, round pupil; 12, 10, '00—band cut in two.	None	12, 17, '00; +9.50 ⊃ +1.50 C. ax. 130°. V. = 6/VI.
36, O. S., J. L., age 67.	12, 3, '00—(dull knife) pupil remains oval, up and out.; a few flakes of cortex in A. C.	Without incident	None	12, 21, '00; +10 ⊃ +1.75 C. ax. 180°. V. = 6/VI.
37, M. P., age 68. .	Opr. smooth; small conj. flap; large quant. of soft cortex fol. a large lens; small, central, round pupil.	3, 1, '01—Capsulotomy	None	V. = 6/VII½.
38, D. W., age 64. .	4, 1, '01 - Opr. smooth, small amt. of gray cortex in a central, round p.; slight tendency to become irreg. at pupillary margin; becomes entirely round on stroking with lid.	Iris adherent; capsulotomy; sees time on watch; pupil oval.	None	4, 15, '01; V. = 6/IX. Before discharged sud. attack of Iritis, fol. by steamy cornea and increased tens.
39, J. P. R., age 54, O. D.	Feb., '99 operation smooth; central, round black pupil.	Eye recovered without reaction; clear, round pupil . .	None	Mar., '99; +10 ⊃ +1 C. ax. 180°. V. = 6/V.
40, R. F., age 57. . .	5, 6, '01—ether anesthesia; oprera.. smooth; central, round, p., gray cap.	Recovery without incident; round. central pupil; small gray band diagonally across it.	None	5, 27, '01; +11 S. V. = 6/XV.
41, R. W., age 50; O. S.	Operation smooth; central, round, black pupil.	Recovery without incident.	None	+11 ⊃ +3.75 C. ax. 150° V. = 6/VII.

front. The operations were invariably performed on the bed the patient was to occupy subsequently so that the necessity of moving from operation table to bed was avoided. These details I believe to be important since the inevitable muscular tension due to raising the head while applying the roller bandage, or in moving the patient to the bed, favor the reopening of the wound and consequent prolapse of the iris. It is probable that most prolapses occur at this juncture.

The following morning the bandage was removed and the lids inspected. If there was no swelling or undue discharge the isinglass strips were not disturbed. The bandage was reapplied and allowed to remain for twenty-four hours. The dressings were then removed, the lids gently opened, the eye irrigated with warm boracic solution, a drop of atropia instilled and after inspection the bandage reapplied, omitting the isinglass strips from the lids if the anterior chamber had refilled.

The tabulated histories of 41 cases, all occurring at the Wills Eye Hospital, are included in the report. The following is a summary: The operation was smooth, that is to say, without noteworthy incident in 31 cases, and complicated in 10. Convalescence progressed without incident in 22 cases. It was complicated as follows in 19, prolapse of the iris in three, namely, Cases 2, 6 and 31 of the series.

CASE 2.—The patient behaved badly; the lens was extracted with the loop with slight loss of vitreous, but eye closed with a nearly round pupil; wound healed promptly, but the iris was found prolapsed on second day and was excised. On discharge from the hospital, V. = 6/X11.

CASE 6.—Operation smooth, but pupil ovoid. Eserin was instilled and a light dressing applied. In an hour pupil was black, central and nearly round. On second dressing iris was found prolapsed and was excised. There was much opaque cortex, the collection of which back of the iris while still transparent at the time of operation had become opaque, its swelling probably accounting for the tendency to prolapse. V. = 6/X11 at time of discharge from the hospital, with some gray capsule.

CASE 31.—Operation was smooth, leaving a clear, round central pupil. It was found necessary to empty his bladder with the catheter during convalescence. In trying to escape this on the fifth day during the absence of the nurse from the ward he sought the urinal and while straining to urinate felt a sudden pain in the eye. A small prolapse of the iris into the nasal end of the wound was found. Although the eye was white before the accident, it became red and convalescence was protracted. V. = 6/X11 at time of discharge from the hospital. It will be observed that in two cases the prolapse was foreshadowed at the time of operation by the ovoid pupil and a tendency to prolapse. In one of these the patient acted badly. It would have been better to have performed the iridectomy in both cases at the time of extraction.

In the third case the prolapse was obviously due to the patient's imprudence. The pupil was oval in five cases from adhesion of the periphery of the iris to some portion of the wound. In the remaining 30 the pupil was round and central. Conjunctival catarrh occurred in three cases. Iritis, usually of a mild type, but resulting in adhesions to the capsule and a somewhat protracted convalescence, occurred in eight cases, commencing usually from the sixth to eighth day of convalescence. In all of these the capsule became gray and secondary operation was required. Notable loss of vitreous occurred in but one case and then was due to the want of self-control by the patient. There was slight

loss in two other cases, in neither of which did it lead to any notable modification of the result. There was hemorrhage into the anterior chamber three times, twice from injury, once without obvious reason. In the traumatic cases both recovered without permanent injury; in the third case the hemorrhage was profuse, quite filling the anterior chamber and the patient recovered with V. = 6/LX.

The nasal end of the wound became infected in one case, but prompt treatment arrested the progress of the ulcer, but left the periphery of the iris adherent to the wound at that point causing a slightly ovoid pupil.

Secondary operations were performed in 14 cases. An exceptionally favorable result was obtained in one patient. Both eyes were operated upon at different sittings resulting in both in central, round, freely acting pupils and V. = 6/V in each eye. He enjoys binocular vision both for distance and in reading. But one loss is to be recorded. The patient left the hospital with V. = 6/ VII ½, but returned in two years with vision sunk to 6/XV due to a gray capsule, following "a cold" in his eye. A capsulotomy was performed followed by no reaction and V. rose to 6/VI. He received his discharge from the hospital on the fifth day with the eye white. He returned the following day with the eye flushed and painful. There was a gray point at the site of the corneal puncture which was rapidly followed by purulent panophthalmitis and loss of the eye.

The visual results were as follows: V. = 6/V in 5 cases; 6/VI in eight cases; 6/VII ½ in 5 cases; 6/IX in seven cases; 6/XII in seven cases; 6/XV in 2 cases; 6/XX in 1 case; 6/LX in 1 case; good in 2 cases; no record in 2 cases; total, 40 cases.

The acuity of vision in many of the cases was recorded at the time of their discharge from the hospital. It is probable that later study would have shown better vision. In some instances when V. = 6/XII secondary operations were not attempted since that vision was sufficient for gross pursuits and further risk was not deemed advisable.†

TEMPORARY CLEARING OF A CATARACTOUS LENS.*

HIRAM WOODS, Jr., M.D.

BALTIMORE, MD.

The writings of Risley, Jackson, de Schweinitz, Weeks, Knapp, Pyle and others, have introduced into the management of partial lens opacities considerations which make the old and easy classification of incipient and ripe cataracts unsatisfactory to the observer, and unjust or cruel to the patient.

A few clinical truths seem to have been firmly established. We know that the situation of early opacities is of prognostic importance; that senility is neither the only nor the most important factor in etiology of so-called primary senile cataract; that the uveal tract, especially the choroid, should be minutely studied; that "spontaneous cures" now and then occur from absorption, with or without capsule puncture, or from luxation; that hygienic, optical and medicinal care are of importance, and seem to retard progress of lens-clouding: that ripening operations are unreliable, and probably entirely unnecessary; that if the opacity interferes with vision to a great degree, and is non-progressive, extraction of so-called immature cataracts is often a safe procedure. All these things must be considered in every case of partial lens-clouding. But there is coming up in late years another question which has, at present, a greater social than scientific aspect. I mean the usefulness of the alleged cures for cataract without operation. I am not aware of any well authenticated observations, from men whom we instinctively believe, tending to prove that massage, electricity, or "absorbing drops" can be depended upon to give results obtained by inventors of the method, when used by others. Yet patients sometimes bring us accounts of alleged cures. We attribute them to the use of atropia or eserin, to a faulty diagnosis or intentional deception. Doubtless one or another of these explanations covers the great majority of such cases. Yet we know that lens opacities often follow or accompany other eye lesions which resolve. Fuchs speaks of clouding of the lens as a symptom of choroiditis, while Dr. Risley's paper, published in 1889, impresses the fact. A few reliable reports of clearing of lens-clouding are found. At the meeting of this Section a year ago such cases were mentioned and are recorded in The Journal, American Medical Association, of Dec. 15, 1900. Dr. Bates of New York saw two cases cured, and one greatly improved under treatment by Dr. James E. Kelly. Save that the patients said they were made to drink a great deal of water, no clue is given to the treatment. A still more important observation was that of Dr. Ring of Philadelphia. He saw lens opacities disappear in a specific patient under iodid of potassium. Such cases suggest the question: Is there a kind of lens-clouding which improves as the underlying cause, probably choroiditis, gets better? If, following out the reasoning in Dr. Weeks' paper a year ago, "the development of cataract is due to a departure from the normal in the nutrition of the lens," and if "hyperplastic or degenerative changes" are thus brought about, will these changes in the lens improve as the cause of malnutrition disappears? Consensus of opinion is against such occurrence. Dr. Risley,[1] discussing the papers of de Schweinitz and Weeks, after tracing the etiologic connection between choroiditis and cataract, said: "I argued that if I could arrest the cause by treatment, I could probably arrest the progress of the opacity. . . . We never see the slightest disappearance of an opacity in the lens. When an opacity is formed in the lens, you can rest assured it will remain there." Dr. de Schweinitz in his paper[2] quotes Alt: "The choroidal disturbance yields, but the formation of the cataract goes on undisturbed in its slow and steady progress." In his remarks, Dr. Risley traced the association of choroiditis with commencement of lens opacification. He argued that the rest, obtained by partial exclusion of light, caused the disease of the choroid to subside. Thus the lens opacity becomes non-progressive. It seemed to me, after reading these papers, that the case herein reported was sufficiently important to go on record. It is not one of spontaneous recovery without operation, for it eventually came to operation; but extensive old choroidal disease existed when lens opacities were first noticed; there was a quiescent period of nearly five years during which the choroidal disease remained inactive, and the lens opacities non-progressive, or nearly so. It was impossible to secure rest to the eyes, almost unremitting near work continuing. The cataract, seen

† I wish to acknowledge the efficient aid of Dr. E. S. Saylor in collating the histories, and in preparing the accompanying table of cases.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

2. Ibid., Dec. 8, 1900, p. 1467.

after an interval of eighteen months, was apparently mature. In six months more it partially cleared, and an area of recent choroiditis was found. With increased exposure to light, through this partial clearing, and at least a moderate participation in work as possible causes, there was renewed advance of opacification, though no new chororoidal disease developed.

Mrs. E L., 72 years old, first consulted me April 9, 1890. She had been nearsighted all her life, and was wearing —9 D. for near, with occasional use of —16 D. for distance. The latter gave about 4/200 in each eye. Without glasses Mrs. L. read Jaeger 1, at two and a half inches with the right, at a perceptibly shorter distance with the left eye. Her reading lenses increased this distance to 5 inches. Beyond this, she could not read. Mrs. L. has devoted her life to literary work. Her capacity for work is almost incredible, considering the condition of the eyes. Preferring to work without glasses, her reading and writing have been done at such distance as, to use her own words, "seriously to interfere with the integrity of her nose." I could not improve vision, her —16 D. correcting all the myopia. Fundus of each eye showed large but old and limited choroidal atrophies, mostly in the neighborhood of the papilla. The foveal region was good. The left lens showed an axial nuclear opacity, rather a central deep cloud than spoke-like striations. In the lower and external periphery of both right and left lenses there were opaque streaks. Over two years—to August, 1892—passed before my second examination. A central deep cloud in the right lens was the only change observable. In July, 1893, distant vision was the same as three years previous. The left eye had lost near vision from 1 to 6 Jaeger. The central haze noticed in right lens a year before, and the opacities of the left lens seen at the first examination were unchanged. So was the fundus in each eye. After July, 1893, I did not see Mrs. L. until Dec. 31, 1894. Her daughter, a physician, had reported to me from time to time. Her reports were that her mother was doing constant work; that it was useless to try to stop her; that the left eye was practically blind, and that Mrs. L. was not coming to the city to see me until she was ready for operation. She came, however, for examination the last day of the year, 1894. No change was noticed in the right lens. The left eye had only l.p. January 1, 1895, full homatropin dilatation revealed a thin rim of red reflex at the equator. The rest of the lens had lost its transparency. Its color was reddish-yellow or amber, much darker than is ordinarily observed. No sector reflex was obtainable by oblique illumination, nor iridic shadow. I was careful to exclude an anterior vitreous opacity. Operation, though urged, was postponed until the summer, on account of the expected absence of Mrs. L.'s daughter. Six months later, in June, 1895, I went to the country home of Mrs. L. prepared to operate upon the left eye. A letter from her daughter to the effect that her mother's eye was free from conjunctivitis or other contra-indication was the only news since the examination on January 1. Mrs. L., on meeting me, wanted to know if cataracts ever cleared up. I made the orthodox reply, and went on with my preparations. She then told me that for some time she had been seeing better with the left eye, and counted my fingers at four feet. Ophthalmoscopic examination showed the fundus clearly. The axial opacity seen in the beginning and the inferior external striations on the equator were unchanged, but between the central cloud and equator the lens substance was transparent. Under homatropin a careful examination was made of the fundus. A small extravasation was found a little to the foveal side of the papilla, and below the horizontal meridian. This was subretinal. The vitreous showed a number of small muscæ. The latter and the extravasation were new. It seemed reasonably clear that an acute choroiditis had ensued which I had had no chance of observing; that the reddish-yellow lens opacity was secondary to it, and that this opacity had cleared with recovery of the choroiditis. The right eye had not changed. Three days later in my office with dilated pupil, the left eye had 10/200 d.v. with correcting glass, against l.p. six months previous, and read 4 Jaeger. I now watched the case as regularly as I could. With undilated pupil, after two months, the fundus was less clearly discernible. On June 16, 1896, definition was difficult even with dilated pupil. Vision was reduced to counting fingers at 18 inches. More hard work was in contemplation, and on July 14, 1896, I removed the left lens with iridectomy. At the time a faint outline of the fundus was discernible, through dilated pupil. There was less opacity than in January preceding. The color of the nucleus after removal was dark red. Considerable soft substance was left, the anterior chamber becoming filled with it. This was soon absorbed. A capsulotomy was done in October, 1896. Ultimate result was, and still is, 20/30 distant vision with +2 Sph. ⊂ with —7 Cyl. Ax. 90°. Plus 7 Cyl. Ax. 180° enables her to read and write at ordinary distance. The right lens has undergone no change since 1896.

842 Park Avenue.

DISCUSSION ON PAPERS OF DRS. RISLEY AND WOODS.

Dr. F. C. Hotz, Chicago—The subject which Dr. Risley brings before us is one that has been under discussion for a great many years. It is a debated question of the simple or combined extraction of hard cataracts. We know the simple extraction was abandoned at its time on account of the frequent losses by suppuration of the cornea and the place of incision was selected which was less susceptible, but making an incision too far in the periphery made it difficult to extract the lens without an iridectomy. Since we know the true nature of suppuration, and since we know how to prevent infection during operations, the peripheric incision has been abandoned and the cut placed again in the cornea, but not so far as previously. The advocates of a return to the simple operation have sometimes been so very bitter in speaking about those favoring the combined extraction that it is really refreshing to listen to such a paper as we have had this afternoon and to hear from a gentleman known to be so conservative, and who always listens to and studies both sides of a discussion. In passing before my mind the papers and discussion published on simple and combined operations I have often wondered whether it was worth while spending so much time and brain matter trying to settle the question of which operation should be done. I think if we get down to actual facts the results in both operations are about even and the apparent advantages of the one method are counterbalanced by some advantages in the other.

The combined operation is applicable to all cases; the delivery of the cataract is easier and the removal of cortical remains can be done more thoroughly. The simple operation can not be done under certain conditions, as rigid iris and posterior synechiæ; it leaves the pupil round and mobile, but always exposes the eye prolapse of the iris with all the serious consequences of this accident. If one has lost an eye successfully operated on, by this accident one may well ask himself the question whether the advantages of the circular pupil are so important as to subject the eye to any chances. Our first duty toward our patients is to employ the safest method, and as long as we can not prevent the occurrence of prolapse of the iris I personally favor the combined operation.

Dr. C. F. Clark, Columbus—I select my cases, and prefer always the simple extraction when I can do it, but I have such deep admiration for anything that Dr. Risley does or says upon such a subject that I was rather surprised at one point in his remarks. I have for years followed the plan of thoroughly irrigating the anterior chamber and have never had occasion to regret it. There must be some inconsistencies in the technique by which different men obtain their results; this is probably due to the personal equation, for I find a great many men opposed to this method. I use the pipette with salt solution and get out very thoroughly all the cortex I can after using the cystotome to outline the central portion of the capsule, which I remove as often as possible, stirring up and removing as much of the cortex as I can before removal of the lens and then irrigate again. I obtain good results and see no reason why irrigation should not be done. If there is any strong argument against this method based upon experience with it it would be a great pleasure to me to hear that argument.

Dr. Edward Jackson, Denver—I think there is no contest between the simple and combined extractions. The question is: Shall we ever do a simple extraction, and if so in how many cases? I do not know of any one who would not do an extraction with iridectomy in certain cases. I do the simple extraction largely because I believe it is the simpler operation. It presents the difficulties of a new operation to one not familiar with it. But beyond that I think it does not present any greater difficulties than the combined extraction. Furthermore, I do it because I think it gives better visual results. By that I do not mean that the average of vision as tested with the test card is essentially different from that obtained after the combined extraction. But there seems to be the same difference between the results of simple extraction, and an extraction with an iridectomy of considerable size, as between the vision with correcting lenses when the eye is under a mydriatic and when it is not. You may get as full vision under a mydriatic, but anyone who has experienced it knows that it makes a great deal of difference in the comfort with which he sees the same letters. I think the amount of light which does not contribute to perfect vision, entering the eye after extraction with iridectomy, is on the average very much greater than after simple extraction. I have had a number of persons who after simple extraction did not habitually use their glasses for distant vision. They had small pupils and saw well enough without them, although they had required at the test case just as strong glasses, 10 or 12 diopters, as is usual. That is not the most important result, to be aimed at for itself; but it indicates somewhat the practical value of the resulting vision. I would like to add, as contraindications to simple extraction, special prominence of the eyeball, and the habit on the part of the patient of nipping the eyelids together. In such cases there is great danger of prolapse. Among negroes, particularly, with strong lids and prominent eyeballs, the danger is very much greater than among Caucasians.

As to the matter of irrigation, I agree with Dr. Clark that I have never seen any reason to regret having used it, though I have seen the irrigator do harm when it was awkardly used. For five years, however, I have used it in but few cases, and now I find myself going to operation most frequently without my Lippincott syringe. This is because I think the cases have cleared up as well without as with irrigation.

Dr. J. L. Thompson, Indianapolis—It is useless to consider whether we will do simple or combined operations. That has been argued over and over, but it is my opinion that the gentlemen will come back to combined operations as they get fewer cases to operate on. We know what a beautiful thing it is at first, but when we have a prolapse a few days afterwards, we wish we had made an iridectomy. I have never lost a case after a preliminary iridectomy. We have a great many farmers to operate on in my neighborhood and from their life in the bright sunshine they acquire the habit of squinting the lids so that it is difficult to avoid doing an iridectomy even while making your corneal incision. We should never attempt to do a simple extraction on a colored woman—with the man it is all right—but with the woman their natural tendency is to yell immediately after an operation just as it is after a baptism.

Dr. Hiram Woods, Baltimore—I would like to ask Dr. Risley to say something about the use of eserin immediately after the operation. There has been considerable discussion over the question whether the contraction of the pupil by eserin does not give a larger surface of iris to be washed out by the secretion of aqueous humor and for that reason it has been proposed to use atropia. I notice that Dr. Risley used eserin in all his cases. When I saw the title of Dr. Risley's paper I looked over my last fourteen cases of simple extractions and found that I had one hernia. Atropia was used always before operation and nothing afterwards. The eye is inspected on the second day, and atropia used if the corneal wound has closed without protrusion of iris. The crucial feature, it seems to me, in the question of simple extraction is careful study of the eye condition before operation.

Dr. Risley, in closing—As stated in the paper, I abandoned irrigation because I thought it was harmful. I am, however, free to admit that the correctness of this opinion, like many others we adopt as the result of daily observation, is difficult to demonstrate. It is nevertheless true that since abandoning irrigation in perfecting the toilet of the eye I have had less trouble from prolonged redness of the eye and fewer cases of striped keratitis. Dr. Jackson remarked that he was no longer careful to have the irrigation syringe at hand, a fact which may possibly be explained by some doubt in his mind also as to its necessity or expediency.

In answer to the inquiry regarding the use of eserin, mentioned in the paper, I will say that I always operate for extraction with a dilated pupil. At the beginning of the operation a few drops of eserin solution, ½ gr. to the ounce, are instilled. The effect of this is to keep the pupil contracted for an hour or more at the most critical period for the occurrence of prolapse of the iris. After the wound is closed and the anterior chamber partially restored, which probably occurs in most cases within the first hour, the atropia reasserts its sway over the pupil.

I was much interested in Dr. Wood's paper. I regard his case as an excellent demonstration of the correctness of the views expressed in my paper, to which he referred, "the etiology of incipient cataract." I have not always found it easy to say that a given gray opacity was situated in the posterior cortex of the lens, since disease of the anterior portion of the vitreous, directly back of the lens, may present much the same appearance. Disease of the uveal tract with vitreous haze may be associated with opalescence and swelling of the lens and peripheral spicules of opacity. I have again and again seen the opalescence, and swelling of the lens, together with the vitreous haze clear up under treatment, with great improvement of vision, but I have never seen an opaque spicule disappear, a statement which, as I remember the statement in Dr. Wood's paper, is borne out in the history of his case.

Treatment of Stammering.—An editorial in *Medicine* for September states that all that is necessary to cure stammering is to teach the patient to breathe correctly. In the majority of cases the stammerer is simply affected with a want of promptitude in the vocal mechanism. He attempts to speak when there is no air passing through the larynx, and consequently no voice. It is only after a number of grimaces and false starts that he finally brings into action the muscles of respiration and succeeds in passing a column of air through the larynx. All that is necessary is to teach him to properly vocalize, namely, to expire evenly, producing a tone with the larynx to which is superadded a position of the oral mechanism necessary to produce the sound required. Attention should never be directed to the mouth, always to the respiration. It is a mistake to suppose that stammering will be outgrown. When patients recover it is due to their conscious efforts to overcome the defect, rather than to any natural tendency to its disappearance.

THE ENUCLEATION OF THE EYE IN TWO MINUTES BY A NEW METHOD, WITH DEMONSTRATION.*

A. T. MITCHELL, M.D.

VICKSBURG, MISS.

The realization of the occasional need for simplifying this operation and of making it quicker, whilst at the same time preserving an equally good stump, led to the development here described.

The classical enucleation is that of Arlt where the conjunctiva is incised around the periphery of the cornea and dissected back, in fact deliberately turned back so as to expose the tendons, which are raised on the scissors and snipped in the succession, of one lateral and then two recti in the vertical plane preceding the nerve section. Bonnett also dissects the conjunctiva, raises the tendons on a hook and cuts all of the recti before severing the nerve. Knapp follows Arlt, with the exception that he does all his dissection on the hook. Arlt's procedure is deservedly the classical one, and will probably be the one followed in nearly every suitable case by nearly every operator inasmuch as the scissors find the tendons as well as the hook and cut them in addition. If the preliminary dissection of the conjunctiva as a separate step made all around the cornea in the above operations could be dispensed with, and Arlt's use of the scissors to find and cut the tendons at the same time be made to go a step further and include the conjunctiva too, would it not be an improvement? We call his operation the classical one because after his circular severance of the conjunctiva he gets his forceps fixed in a rectus tendon with one hand whilst with the other the scissors find and snip accurately and quickly the tendons that many operators probe for with a hook first, find, lay the hook down, take up the scissors, cut and so on for each tendon separately.

It is only in the intact eyes that my operation is applicable, but in them the operation differs in the elimination of the preliminary dissection of the conjunctiva in the above common operations. So far as I can find, only the method known as the Vienna method can be urged as identical. That it may be compared I will quote in full the description of it written by Kollock,[1] of Charleston:

"The conjunctiva is opened near the outer or inner margin of the cornea and dissected away over the attachment of the rectus muscle, which is caught up and divided. The scissors are then passed rapidly around the ball, dissecting it from the orbital tissue until the nerve is reached and divided. The arms of the speculum are opened and pressed back into the orbit, to force the ball from the socket. The conjunctiva, muscles and orbital tissues are then easily divided by rotating the ball." "A careful reading of this will show that the nerve is divided before any muscle but the internal or external rectus. These explanations of the methods heretofore used will, I trust, show that the following description has some points about it that differ from the conventional."

The technique that I hope saves time and injury is in detail as follows: A curved needle with a strong double thread is passed well into the scleral tissues to give a stout hold on the eyeball. The conjunctiva was snipped vertically over the insertion of the internal rectus. The lower blade of a half-curved pair of scissors is passed under the tendon and is raised into view.

The tendon, capsulo-bulbar fascia, trabeculæ, subconjunctival connective tissue and conjunctiva, incised at one time, not quite to the end of the scissors. The lower blade, still in the capsular space, is advanced under the superior rectus and a similar cut made, the superior oblique and tissues over it next. The lower blade of the scissors is now carefully shifted downward and inserted under the inferior rectus, which with the inferior oblique is similarly divided. The bulb can now be rotated outward, and one cut for the nerve and one for the external rectus and tissues over it completes the operation.

There has been no preliminary dissecting up of conjunctiva, no feeling around with a hook, no indefinite snipping in a bloody, obscure field. All operations done with clean, clear cuts are better than if done with a multitude of small piecemeal ones.

If it is possible thus to obtain a similar result with an operation that eliminates a great deal of disturbance of the tissues, it thereby is valuable where, by reason of panophthalmitis we hesitate to enucleate because of the creation thereby of an immense absorbing surface. In cases where a prolonged waiting on phthisis bulbi is our patient's only chance for relief, as we decided because of this fear to create a large absorbing area, the old conjunctival dissection and hooks produced a danger to the meninges; this clean cutting will render possible to enucleate without such danger.

The element of speed is another point I want to call your attention to, and it can be shown to be valuable in some emergencies by a private case. This was a case of absolute glaucoma of two years' standing, that had been treated by hypodermics and a prescription of "papine." The patient came from the interior of the state where the local physicians could not obtain a consultation with an ophthalmologist.

When I found that the morphin or some other cause had given her a functional heart disease, viz., an intermittence varying from one in four to one in thirty, according to the time of the last dose of papine, we saw that a long operation would be unsafe. In the first stage of anesthesia holocain was dropped on the conjunctiva and just before incising, the suprarenal extract. This hurried the sensory paralysis and provided against blood obscuring the field. Instead of the thread, an artery forceps was fastened to the stump of the cut internal rectus tendon, and here the anesthetist made me stop, as the pulse was intermittent and thready. Repeated attempts to proceed had to be abandoned, and only by the most careful watching with the phonendoscope over her heart and one tube in the anesthetist's ear and the other in mine, could we decide to proceed. The eye was taken out in about one and a half minutes, as near as we could decide, and in about ten cuts of the scissors. The patient revived in a few minutes, and she left for home on the fourth day relieved.

The urging of the necessity of preserving the conjunctiva as a factor of importance in the fitting of an eye, can be met by stating that this operation makes a stump that practical demonstration has shown is as good as that of other operations. The curved scissors properly used cut the conjunctiva at about the same distance from the cornea that the preceding operation of a distinct dissection of the cornea does. In this operation the distance from the cornea of the conjunctival cut varies with the nearness of the recti muscles, which is 5 to 8 mm.

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee of the Section: Drs. J. A. Lippincott, Casey A. Wood and H. V. Würdemann.

1. Amer. Text-Book of Dis. Eye, Ear, Nose and Throat, p. 571.

CONCLUSIONS.

1. The method causes so much less traumatism than others that it is available where enucleation has to be done with least possible injury.

2. Where grave reasons obtain against anesthesia a quick operation is the only one that can be considered.

3. Cosmetic considerations are met as well as by other procedures.

4. An operation done quickly, with a few clean cuts, deserves comparison with the same thing most of us have seen the general practitioner take an hour of hacking and probing to do.

THE ROLE OF THE ENDOTHELIUM IN INFLAMMATION.*

E. R. LE COUNT, M.D.

ASSISTANT PROFESSOR OF PATHOLOGY, RUSH MEDICAL COLLEGE, CHICAGO.

It would certainly be superfluous before a body of representative pathologists to give a review of those publications which from time to time for the last forty years have considered the exact position the endothelial cells should occupy as regards their origin and classification. Indeed, the discussion began somewhat earlier, for Henle in a paper on the distribution of epithelium in the human body, written in 1838, noted certain facts which seemed to him to presage a change of ideas regarding the cells that line serous cavities. Not only has the discussion continued until the present time, but it is by no means ended; its very existence furnishes a good illustration of the unity of the sciences pertaining to medicine, for investigators in single branches are unable to harmonize the results of their own researches with those made in other departments; it is also often apparent that there is not entire unanimity of opinion among the authorities of certain special branches. However, as concerns some discordant ideas harmony has been attained, as for instance the agreement between embryologists and pathologists that the word "endothelium," since its introduction by His, has been applied to cells that differ in origin and therefore in the properties with which they are endowed. Most pathologists show a willingness to accept for the present the views advanced by Kölliker and Waldeyer, that the endothelium of the serous cavities differs from that of the blood channels, and that the former is more closely allied to epithelium; this is shown by the frequency with which they refer to the lining cells of serous membranes as epithelium. The usage, unfortunately, is not universal, and it is so far from being so that this consideration must embrace the cells for which the term "endothelium" was originally devised. Some anatomists as well as some pathologists, even though they accept the idea of a different origin for the two sets of cells, insist upon referring to them from the morphologic standpoint alone, and for all the cells use the word "epithelium." Although this may be advantageous by reason of its simplicity, it is nevertheless a retrogression: it is certain to confuse him who is unable to cast off at will those conceptions of the cells that concern other properties than those of morphology.

The attempt of the student to co-ordinate the perspectives of some subjects exposed to his mental vision by teachers in different lines is often distressing; for example, the difficulty with which he labors to arrange in their proper connection the facts obtained in the necropsy room and the laboratory relating to Hodgkin's disease, with the clinical features of that malady. The task is certainly as great to arrange for a proper comprehension, ideas of cells that have a morphologic unity, that however differ in genesis and in the varied activities of pathologic processes. Therefore, if for no other than purely pedagogic reasons, the difficulties should be removed as far as possible. It is doubtful whether this can be accomplished by having for certain cells various terms to designate at one time their morphology, at another their eventual fate or genesis. There is less need of new terms than there is for some leading mind to arrange a conformity of nomenclature. Of terms we have a plenty; to the previously acquired terms endothelium and epithelium, embryology has added "mesothelium" and pathologic histology "perithelium." The obstacles to a clearer understanding of the entire question are about to be augmented by the present tendency among embryologists to regard the vascular endothelium as different in origin, not only from that of serous cavities, but also from that lining the lymphatic channels.

However great these differences of opinion as to the genesis of certain of the so-called endothelial cells may be to the embryologists, it is altogether possible that the importance of these questions for the processes accompanying disease has been overestimated. At least, it is not unreasonable to conclude that the laws of specificity of cells that have found such a universal application to other structural elements would be equally applicable to endothelium. No matter how loosely this is done, it means that when in the course of embryonic development cells are differentiated to line certain channels or to cover certain surfaces, those cells are provided with a function or quality that they will always manifest even under widely varying circumstances. It also means that if such cells are provided with other functions, that these also are retained, and that the functions which form the basis of differentiation are not readily exchanged for others. It also means that when such cells revert to an embryonic condition as so often happens in pathologic processes, a reversion that Adami considers a degeneration, they never attain such a degree of prematurity that subsequent differentiation is possible with other functions and different qualities. In other words, the characteristics which the cells possess when once differentiated are always retained: endothelium remains endothelium and the embryonal endothelial cells is by no means analogous to the cell of the embryo destined for specialization into endothelium. With the acceptance of these propositions, the importance for pathologic processes of questions dealing with the genesis of this or that set of endothelial cells is greatly lessened. This remains true, notwithstanding the perplexity or interest such questions may possess for our confrères, the embryologists. Minot said in the Middleton Goldsmith lecture before the New York Pathological Society, in support of the term mesothelium for the cells lining serous cavities, "We do not have, however, at first a true differentiation of mesothelial and mesenchymal cells; all are undifferentiated, and we can readily demonstrate that the cells are interchangeable;" further, "We find that the mesothelium constantly gives off cells which join the mesenchyma, and we find later that the mesenchymal cells may take on an epithelial arrangement around any of the body cavities, which arise within the mesenchyma itself." That such an interchange of cells is possible during developmental periods is very interesting, but its import-

* Read at the Fifty-second Annual Meeting of the American Medical Association in the Section on Pathology and Bacteriology, and approved for publication by the Executive Committee: Drs. A. Steigel, W. S. Hall and L. Hektoen.

ance to the pathologist would be paramount if it was firmly established that such reciprocation took place subsequent to a time when the differentiation of the endothelial cells to line the body cavity was completed.

It must be admitted that the changes which the endothelial cells may undergo in inflammation comprise all the retrogressive processes except that of sudden actual destruction, and all the phenomena included under the terms regeneration or proliferation except those of tumor growth. It must also be accepted that the behavior of these cells in inflammation, their proneness to resist, or their likelihood to suffer great damage, is quite in proportion to their differentiation. The useful knowledge of these cells is such as will enable us to forecast what is likely to happen to the endothelium of a certain region during an inflammation of that part caused by irritants of a certain kind or intensity; such an ability can only be obtained by a knowledge of the changes that have already been noted. Therefore, I shall content myself by a few brief references to certain observations of changes in these cells, trusting that this or that phase of certain researches will not command your attention to the exclusion of broad and fundamental notions of endothelium in general, such as its function, resistance to irritants, and its degree of differentiation.

As the explanations of various physiologic and pathologic problems crowd in upon us from the domains of physics and physical chemistry, the interest in the hypothetical selective power of the endothelium of small blood vessels lessens; it grows more improbable—to use the words of Thoma—that "the endothelium lining the capillaries represents a secreting membrane which transforms nutrient material brought to it and gives off metabolic products." It is quite likely that the same causes that bring about alterations in the character and quantity of the transudate also produce such modifications in the walls of the capillaries as will allow of its passage outward.

Adami has emphasized the important part the endothelial cells play in inflammation, especially the power they possess of absorbing non-motile bacteria and acting as phagocytes; he also calls attention to the alterations they suffer in shape; the nucleus as well as the cell body becomes larger; the former contains more chromatin and the cell projects into the lumen of the vessel. It is clear from the context that he has reference to vascular endothelium and particularly that of the capillaries. Borst in producing peritonitides in guinea-pigs and rabbits with streptococci and colon bacilli, found that the endothelial cells lining the cavity underwent granular swelling, desquamation and became entirely filled with bacteria. This would seem as though the cells were undergoing destruction. On the other hand, Wallgren, who participated in the great work carried out by Professor Homén upon streptococcus infections, found that "the diminution of the streptococci in the free peritoneal fluid shortly after the injection is due not only to a reabsorption and phagocytosis, but also to an accumulation of cocci in the wall of the cavity, where they lie partly free, partly enclosed in leucocytes or endothelial cells." He believes one of the means of defense possessed by the peritoneal cavity is in certain functions of the endothelial cells lining that cavity. Lemaire, among others, has noted the phagocytic action of the endothelium lining the capillaries of the liver against colon bacilli, and Mallory has found the same organisms in clumps of cells of endothelial origin in the mucous coat of the bladder. It is altogether likely that these organisms, if not dead at the time of their incorporation, are deprived of their motility. Broden has described phagocytosis of the bacillus of tuberculosis and the intracellular digestion of leucocytes that contain such bacilli, by the endothelial cells of the peritoneum. The phagocytic action of endothelium described by Mallory, in which the endothelial cells of blood and lymph channels and of the pleural serous membranes incorporate and digest red blood corpuscles, plasma cells and leucocytes, has a very wide bearing. It has been more than once suggested that certain forms of leucocytes have their source in the endothelium, and, if this be confirmed, it can not be held surprising that parent and offspring should exhibit some likeness. This warfare between endothelium and other cells, described by Mallory, recalls that recently depicted by Dominici in a study of the changes in the bone marrow and spleen of the rabbit following inoculation with the bacillus typhosus. So far as the rabbit is concerned the reaction in the spleen is apparently one of cellular destruction; the cells destroyed are produced in the bone marrow; the destroyers originate in the spleen and the conflict is one between leucocytes.

A great part of the knowledge pertaining to the behavior of the endothelial cells in inflammation has been derived from the fierce controversy as to the origin of fibrin in acute inflammation of serous surfaces waged by Neumann, Grawitz and their pupils on the one hand, with Orth, Marchand and their followers on the other. It is quite appropriate to refer to the recent works of Abramow, Herxheimer, Gaylord and Saltykoff in this connection. The contention of the Neumann and Grawitz faction that fibrin was produced from a peculiar degeneration of connective tissue seems to have been definitely disproved. All of the observers find proliferation of the endothelium as a prominent feature of the process, and some, that it may take place by direct division. The new cells may form an unbroken row between the fibrin and the serous coat, or the fibrin may be almost surrounded by newly produced endothelium. Often the rows of cells occur double, one covering the under surface of the fibrin and one the outer surface of the serous coat, with a cleft between them. Rather than recognize that such subfibrinous rows of endothelium were regenerated from the cells of the serous coat, Neumann traced them to the endothelial cells of lymph channels, even although he admitted that such a replacement was contrary to the specificity of the cells derived from the lining of the celom. Saltykoff, who used material from necropsies, found in three of sixty cases many layered formations that resembled stratified epithelium; similar appearances have been described by Sultan in a case of chronic periorchitis, and by Heinz from the injection of iodin into the pleural cavities in animals.

It seems to be universally accepted that the fibrin ferment may arise in part at least from the destruction of endothelial cells. Hauser, Graser, Birch-Hirschfeld, Abramow and others have described these cells staining poorly, located at the centers of areas of coagulation, and Saltykoff has noted fibrin within the cells and continuous with the threads which enclosed and covered them. Many authorities have alluded to the analogy between the fibrinous inflammations of serous surfaces and the croupous or diphtheric inflammations of mucous surfaces, in the necrosis of superficial cells and the formation of fibrin that is observed in both. There is a disposition to consider both, as designed to protect the underlying tissues and to fulfill in this manner the general

plan of adaptation that obtains in the inflammatory action. The cohesion between fibrinous exudates and serous membranes is sometimes remarkable for its strength; before the close and intricate meshwork of the as yet unorganized exudate can be broken, the underlying connective tissue will tear; this intimate union is due to the interweaving of threads of fibrin among the endothelial cells (Saltykoff). Other retrogressive processes than the coagulation necrosis that accompanies the formation of fibrin, do not seem to affect the endothelial cells to any great extent in inflammation. It is true that fatty metamorphosis of the cell, karyorhexis, cloudy swelling or an appearance of granules in the cell body have been described as well as hyaline degeneration, but these changes as they affect endothelium have not formed the basis of any considerable study. The endothelial cells of blood vessels are often found in sections, lying loose in the channel, where they form clusters of spindle-shaped cells that are very liable to be mistaken for emboli.

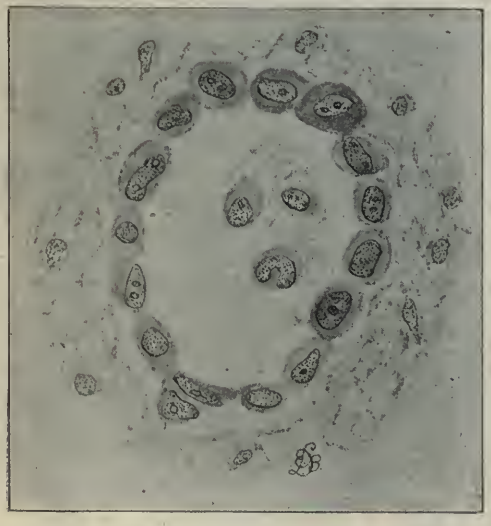
When the endothelial cells of serous membranes do not suffer necrosis they undergo a lively proliferation. Borst, studying organization of thrombi in the peritoneal cavity, found evidences of multiplication on the second day; Büttner, producing peritonitis by cultures of the staphylococcus aureus, found karyokinetic figures in these cells at the end of twenty-four hours, and Maximow, in his work on the healing of ovarian wounds, detected on the second and third days numerous dividing nuclei in the covering cells of that organ, which are supposed to retain many of their embryonic qualities. Heinz and Abramow have made similar observations. Roloff found foreign bodies covered by endothelium in fourteen hours, and Hinsberg after two days. In these respects the early and active multiplication of the endothelium of serous membranes is very similar to that which takes place in the blood vessels and the heart following the formation of thrombi.

Many observations have been made of the formation of giant cells by endothelium in both blood and lymph channels and in serous membranes. After Orth described them in the omentum in 1887 many others noticed them; previous to this Meyer, Buhl and Wagner described them in the pleura and pericardium, and the last named observer noticed some with twenty to thirty nuclei; all of these belong to the class of foreign-body giant cells; Marchand and Herxheimer have emphasized the great resistance of the giant cells, for they seem to escape destruction for longer lengths of time than the adjacent endothelium. Herxheimer gives reasons for their origin in the serosa endothelium that are sufficient to convince the most skeptical; he says: "It is made certain that the giant cells are derived from the covering cells and not from the connective tissue by finding them on both sides of the retained row of endothelium, in the midst of such, or in direct continuity with the endothelium with which they correspond in tinctorial peculiarities, both of nuclei and cell body." He believes that they are produced by the coalescence of separate cells. In this faculty we find another correspondence of properties between the endothelium of the serous membranes and that of the vascular apparatus, for it has been repeatedly affirmed that the endothelium of blood vessels may form giant cells.

In his well-known study of the histology of typhoid fever, Mallory has brought forward facts concerning the proliferation of endothelium that have fully as wide an application as those dealing with phagocytosis. He found that the toxin in this disease caused multiplication of endothelium lining blood and lymph channels in the intestine, lymph glands, bone marrow, spleen and some other organs; the newly produced cells may accumulate at the points of their formation or they may be carried to distant places.

To impress you with the broad bearings that the results of Mallory's researches have upon pathologic processes in general, allusion may be made to a case reported by v. Notthaft as pseudo-leukemia in which the clinical details and the gross anatomic changes were those of lympho-sarcoma. In the histologic examination, proliferation was found in the endothelium of the lymph channels in the skin, where the new cells had often assumed a cubical form; a proliferation of the endothelium of the capillaries of the spleen had also taken place, and, in the lungs, liver, kidneys and pancreas, a similar process is described in capillaries supposed to belong to the lymphatic system. The cells lining all these channels were usually cubical, and among these giant cells were frequent; the channels were irregularly dilated. Formations resembling the tubules of glands were abundant in the lymph glands. The nodules that resembled tumors were composed of polymorphous cells and in these giant cells and cell inclusions were numerous. Largely from the evidences of proliferation of the endothelium of such varied localities as the spleen, lymph glands, blood and lymph channels, v. Notthaft debars the diagnosis of tumor in favor of an infection. Yet another citation to illustrate the significance of such processes as Mallory has described: In a case of splenomegaly, Boivard, working under the guidance of Prudden, found proliferation of the endothelium of the sinuses in the spleen, perisplenic and mesenteric lymph glands, and of the perilobular lymph channels in the liver. He refers to the classification of this disease by the French authors as primary endothelioma, a position which Herzog has recently taken in a consideration of two cases before the Chicago Pathological Society. Boivard excludes tumor growth in the following words: "We are driven to regard the process as a hyperplasia of the spleen, characterized by an unusual development of endothelial cells and the transformation of a considerable part of the organ into dense connective tissue." If the diffuse nature of the process in the spleen could lead Boivard to exclude tumor, as seems altogether reasonable, it may be that certain other diffuse growths, characterized at present as endotheliomas, may in time be removed from this category. These references serve to indicate a possible connection between tumor growth from a multiplication of endothelial cells and other widely varying conditions ensuing from the same process. Mallory has strongly emphasized the bestowal of malignant qualities upon cells by toxins.

Of much less significance, but none the less interesting, are certain other results of the proliferation of endothelium. There have been observed in various situations, usually, however, adjacent to serous membranes, rows of cells that form gland-like channels or tubules; these formations have not infrequently led to the apprehension of tumor, on account of their great resemblance to similar formations in cylindrical celled carcinoma. They have been noticed either in human tissues or in experimental work upon animals by Apel, Paltauf, Marchand, Orth, Graser, Gaylord and Heinz. Saltykoff saw them between masses of fibrin and the original serous coat. Ribbert, in the "milk spots" of the pericardium, and Herxheimer, in a case of chronic fibrinous pericar-



ditis, by means of serial sections have traced their connection with the cells of the adjacent surface. Ribbert believes the appearance of tubules is due to cross sections of clefts. Riese has noted such tubules with cystic formations in organized deposits on the Fallopian tube, and Nagel in similar conditions of the ovary. In some tubules of this sort that I have described in reporting a case of carcinoma of the Fallopian tube, the nuclei of the cells were much poorer in chromatin than is customary with nuclei of carcinoma cells. There is no question

Tubules formed by endothelial cells. From the posterior surface of the uterus.

of the analogy between such activities of endothelium in the organization of fibrinous exudates and the proliferation of the endothelium of blood vessels to line lacunar spaces in thrombi that are undergoing organization (Welch).

Other illustrations of the disposition of endothelium to cover surfaces are furnished by Maximow, who found that wounds of the ovary when left unclosed became lined by cells from the surface, and by the recent reports

Tubules formed by endothelial cells. From the posterior surface of the uterus.

of cysts of the spleen by Ramdohr and Schmidt. The last named authors relate, in separate articles, altogether seven instances in which the spleen was covered to a greater or less extent with vesicles of various sizes filled with clear fluid. In some cases the spleen appeared as though besprinkled with dew drops, in other cases the cysts were limited to certain areas and some were encountered the size of cherries. These were all explained by the growth, through defects in the capsule, of the covering endothelium.

The ability of endothelium to form connective tissue or the active participation in cicatrization of the endothelium of certain regions, are questions that have formed the basis of many researches and many polemics. Without doubt, the older belief that this capacity was inherent in all varieties of endothelium owed its general acceptance, in a measure, to the accounts published fifteen to twenty-five years ago dealing with the organization of thrombi. That the endothelium of blood vessels should possess such a property, perhaps met with the more ready welcome, since it was so thoroughly in accord with the prevailing ideas as to the genesis of the cells. With the entrance of controversies as to the origin of the endothelium of certain situations among the embryologists, it is but natural that the endothelial or epithelial nature of certain of the cells in question should be reflected by pathologic problems. So far, the endeavor has been to separate the endothelium of serous membranes from other forms, and it is with these cells that contrary opinions have been agitated. The prolonged interest in these questions is largely to be attributed to ignorance of the exact methods by which fibers are formed normally; with the definite proof of the secretion theory or of their direct production by fibrillation of cells, or of the conditions under which either of these processes occur, will come a seasonable time for investigations to determine how this or that group of cells may share in the development of pathologic fibrous tissue.

It is generally accepted that endothelial cells may assume certain embryonal properties in inflammation and assist in the formation of granulation tissue, but there the trail is lost; differences between embryonal cells of diverse geneses as they occur in this tissue are not sufficiently marked, that the subsequent behavior of separate forms is readily traced. Büttner, in some experiments with peritoneal endothelium, found the intercellular bridges or prickles previously described by Kolossow, but there are no statements or illustrations in his report that would lead one to infer that they are retained as the cells undergo changes. Although there is no consensus of opinion as to the rôle endothelium plays in the growth of cicatrices, yet some recent works, such as those of Muscatello, Heinz, Hinsberg, Büttner and Herxheimer, point strongly to the necessity of divorcing the lining of the pleuro-peritoneal cavity from other forms of endothelium, at least so far as some of its qualities are concerned. Certain observers who concluded from experiments that the endothelium of serous membranes was directly concerned in the production of organized adhesions, have recently moderated their statements as to such an eventuality (Graser, Marchand). Büttner, who repeated Roloff's study of the encapsulation of sterile silk ligatures introduced through the peritoneum, was unable to confirm the conclusion of his predecessor as to the versatility of the lining cells. When masses of fibrin in fibrinous exudates are replaced by connective tissue, the organization always proceeds from the point of their anchorage and this is true in spite of the fact that such masses may have been completely covered over by newly produced endothelial cells from the edges. Even Neumann, who has insisted so strongly upon the "fibrinoid degeneration" of connective tissue, does not believe that the lining cells of the pleura or peritoneum may develop into fibroblasts. Thus gradually and from various sources, as before stated, an agreement has been reached that the lining of the serous cavities—pleura, peritoneum, pericardium and tunica vaginalis—is clearly allied to epithelium.

No doubt some of the work leading to the universally admitted formation of fibrous tissue by the endothelium of blood vessels needs repetition with modern methods of experimentation and technic; inquiry into the behavior of these cells in processes of disease has not possessed the stimulus of a vigorous dispute relative to their origin. Indeed, there are some facts to indicate that our conception of these cells may undergo modifications fully as radical as those already suffered by our views of the serosæ endothelium; investigators have been more occupied with the demonstration that changes peculiar to this or that disease affected certain coats of the vessels to the exclusion of others, or that some one layer was first involved, than with the histogenesis of the lesions. The tissue between the endothelium and the inner elastic membrane—the subendothelial connective tissue—has received very little attention from pathologists; the word intima with quite a uniform disregard of the subendothelial tissue which is also intimal, has become in a sense synonymous with endothelium, and endarteritis with proliferation of the endothelial cells. Although this part of the intima is insignificant in certain vessels, in others it contains numerous fusiform and stellate cells and it is altogether possible that in processes of disease it may be greatly augmented in localities where normally it is made up of a single layer of cells. Langerhans as long ago as 1866 called attention to occasional "granulation cells" in this layer and to their possible pathologic consequence. More recently Hektoen has emphasized the passive part the endothelial cells play in the development of subendothelial, intimal tubercles in tuberculous meningitis, and these he ascribes to a proliferation of cells. Heubner has located the process in syphilitic disease of the arteries in the same position, the subendothelial tissues; although he attributes the accumulation of cells in this region to a proliferation of the endothelium, there are not wanting opponents to this explanation who account for the excess of cells by an infiltration (Köster). Diamond has recently reopened the question of tuberculous meningitis, and in a number of cases found the subendothelial cells forming the intimal tubercles to consist in large part of plasma cells. From these allusions it is evident that the worn expression "thickening of the intima," may in time come to possess another purport than that which it has carried so long of proliferation of the endothelium. If there are to be wide differences of opinion with regard to the behavior of the endothelium of the vessels in such inflammations as syphilis and tuberculosis, and especially in reference to its ability to form connective tissue, the share the endothelial cells take in the more chronic processes accompanying arteriosclerosis must remain mere conjecture; for the opportunities to determine the histogenesis of a chronic inflammation diminish as does the amount of granulation tissue which develops in its course. Briefly, we are forced to the conclusion that there is ample room for further proof of the production of fibrous tissue by the endothelial cells lining the blood vessels. Many interesting questions must remain untouched, such as the effect of the inflammatory process upon the cells lining lymph channels and the large joint sacs, and problems dealing with endothelial cells that are differentiated for special functions, such as those lining the channels of the blood forming organs. It will be necessary to have the results of more inquiries than are as yet available to obtain comprehensive impressions of the cells of some of these locations. Sufficient has been said, I am sure, to relegate to the endothelial cells an important place in inflammatory reactions, and to call to your notice some fields that offer attractions for investigation.

BIBLIOGRAPHY.

The following are the more important works referred to The article by Saltykow will be found to possess a very complete list of the controversial publications concerning fibrinoid degeneration of connective tissue. Other publications that have proven very valuable are those by Marchand, Herxheimer, and Büttner.

Abramow: Ueber die pathologisch-anatomischen Veränderungen der serösen Häute bei den experimentellen acuten fibrinösen Entzündung; Ziegler's Beiträge, 1898, xxiii, p. 1.

Adami: Inflammation; A System of Medicine by many writers, edited by T. C. Albutt, vol. i, p. 54.

Ibid.: On Growth and Overgrowth (etc.); Festschrift in honor of Abraham Jacobi, 1900, p. 422.

Borst: Chronische Entzündung und pathologische Organisation; Lubarsch and Ostertag's Ergebnisse, 1897, iv. p. 460.

Ibid.: Neue experimente zur Fremdkörporeinheilung; Verhandl. der deut. path. Gesellsch., 1899, ii, p. 176.

Büttner: Untersuchungen über das Verhalten der Peritonealepithelien bei Entzündung; Ziegler's Beiträge, 1899, xxv, p. 453.

Broden: Recherches sur l'histogenese du tubercle et l'action curative de la tuberculine; Arch. de méd. expér. et d'anat. path., 1899, xi, p. 1.

Boivard: Primary Splenomegaly (etc.): Am. Journ. Med. Sc., 1900, cxx, p. 377.

Dominici: Sur l'Histologie de la Rate au cours des états infectieux; Arch. de méd. expér. et d'anat. path., 1900, xii, p. 732.

Diamond: Cellular changes in tuberculous meningitis; Read before the Chicago Path. Soc., May, 1901.

Gaylord: Fibrinous Exudates and Fibrinoid Degeneration: Jour. Exp. Med., 1898, iii, p. 1.

DISCUSSION.

Dr. H. G. Wells, Chicago—Dr. Lemaire demonstrated the action of two different cultures of the colon bacillus. He injected a mild colon culture into the general circulation of rabbits and found that in a short time the endothelial cells of the hepatic capillaries became filled with the bacilli, while the

colon bacilli rapidly decreased in the circulating blood. When he injected a fatal dose of a virulent culture he found that the endothelial cells in part were destroyed, and after a short time the colon bacilli, multiplying in the cells, escaped into the circulation and rapidly increased in number. He found if he injected an antitoxin serum for this colon bacilli and at the same time injected a virulent culture, the number of bacilli in the peripheral circulation sank exactly as when he injected the non-virulent or mild colon bacilli; therefore, he concluded that the effect of the antitoxin is to stimulate the endothelial cells, and immunity, in this case, is due to direct endothelial stimulation by the antitoxin itself. This is based on the similarity of the effect of the virulent cultures accompanying the antitoxin, and non-virulent cultures without antitoxin. Since reading his article I have wondered if that conclusion was warranted, and I bring up the matter at this time hoping someone will speak on the point as to whether the subject of immunity, at least in some cases, is due to stimulation of the endothelial cells or not. I understood Dr. Le Count to say that endothelial cells were characterized by not entering into the formation of tumors. I wish he would make that clear.

DR. E. R. LE COUNT, in reply—I do not believe that Lemaire is sustained in the position he has taken entirely, because we do not know that these bacilli that were incorporated into the endothelial cells of the capillaries of the liver were not dead at the time of incorporation. Further, as regards the production of immunity. You will remember I called attention to the fact that the endothelial cells may give origin to leucocytes, and in the phagocytic properties that the endothelial cells have been found to possess, there was a resemblance in this respect between parent and offspring. It is supposed that immunity may be due in part to the production of anti-bodies, or substances that are in solution; that there is extra-cellular digestion, so to speak; these substances are the product of leucocytes. I do not think it unlikely that the endothelial cells, at least in certain regions, may show a further resemblance to leucocytes in that they also may furnish some of the substances that bring about extra-cellular destruction of bacteria. Personally, I have very little faith in the ability of a flat cell to secrete anything. If the diffuse nature of the process in the spleen in splenomegaly sufficient to exclude tumor, it may be that certain other growths characterized at present as endotheliomas may be in time removed from this category. I have in mind particularly the diffuse endotheliomas of the serous surfaces, of which there are only a few cases on record. One case reported recently by Pollmann occupied in the pleura and peritoneum both. True, it is supposed to have had its origin in the vascular endothelium, and not the serosa, and this fact might explain this tumor as a healed diffuse inflammatory process, such as occurs in both situations. I also had reference to diffuse meningeal sarcomas as have been observed in the cerebral and spinal meninges. The cases of this sort have been collected by Dr. Weaver, 11 in number, and are reported in the third volume of the *Journal of Experimental Medicine*. It is very significant that in 6 of the 11 cases there was no primary tumor reported.

FEAR AS AN ELEMENT OF NERVOUS DISEASES AND ITS TREATMENT.*

JOHN PUNTON, M.D.

KANSAS CITY, MO.

Fear as an element of disease has become so very prevalent and common that its study deserves more than a passing notice. While its universal prevalence is recognized to some degree at least in nearly all forms of disease, yet it is in the departments of neurology and psychiatry that we find its most serious effects and disastrous consequences. Fear is defined by Gould as an emotion of dread, an apprehension the feeling of which in its intense manifestations is called terror or fright. Generally speaking, fear is the expression of a desire on the part of the individual to escape or ward off whatever may seem to threaten evil or work harm to his well-being. It therefore conforms to the instinctive power immanent in man and animals of self-preservation. As such it exists normally in every individual in varying degrees of intensity and subject more or less to the higher inhibitory power of self-control; hence its manifestation depends not so much upon the excitation that causes it as the receptive and restraining power of the recipient. The most casual study of the affective capacity of human beings teaches us that the power of emotional receptivity and power of restraint differs enormously in different persons, so that one can witness the most terrible sights or pass through extreme degrees of danger without apparently producing any special manifestation of fear or dread, while another person subject to the same experiences will be completely overcome by them. In the former case the emotion or fear was controlled by the will or inhibitory power, while in the latter both these elements were weakened or even paralyzed. The foundation of all fear has for its basis a presentiment of danger. This excites or stimulates the emotions through the various avenues of the internal and external senses which in turn responds by a conscious sense of fright or dread presenting every degree of fear and often resulting in a series of reflex motive phenomena in which the whole central nervous system is involved. Its clinical manifestations therefore vary considerably and may be both objective and subjective, involving the motor, sensory, reflex, trophic, secretory, visceral and psychical nervous mechanisms in varying degrees. The more common symptoms of fear are pallid or flushed face, dilated pupils, profuse perspiration, general tremor, with chattering of the teeth, general muscular weakness, so that the knees seem unable to support the body, the voice becomes weak and tremulous, the heart violently palpitates, the respiration becomes rapid and labored, vertigo supervenes, followed by syncope, paralysis and sometimes death. In some cases, however, many of these may be absent and the fear may be almost entirely confined to psychical disturbances which are only known to the patient. The element of fear is so common and universal that there are few persons who have not some besetting fear. With many it is an idiosyncrasy, and by avoiding the object of fear no distress is experienced. But in the great majority of persons a certain apprehension that the dreaded thing will occur or be encountered is constantly before them, which is thus aroused by mere thought or memory of the object or condition, and often where there is no prospect of danger whatsoever. So common and prevalent is this apprehension of danger that it pervades all the ramifications of our business, professional and social life. More especially do we find its pernicious influence affecting those who inherit or acquire a neurotic tendency. Consequently, the nervous, unstable and imaginative, those who by virtue of their faulty organization, suffer more severely from its effects than the phlegmatic and those whose sensibilities are less keen and susceptible. Fear under certain conditions and circumstances and within certain limits may therefore be said to be a physiologic function similar in all respects to that of its opposite attribute joy, but when it reaches an extreme degree and goes beyond the prescribed limits it ceases to be a normal condition, but becomes a pathologic factor. The term fear and morbid fear or patho-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

phobia bear the same relation to each other as health and disease or physiology and pathology, hence they may be used synonymously. It is said that normal fear has as a stimulus something which experience has taught is to be dreaded, while morbid fear may have an external stimulus that to a given individual arouses a dread at once unreasonable and quite out of proportion to the real danger. Morbid fears present no specially distinctive feature as to external manifestations, but the sense of uncontrollable dread seems stronger.

Morbid fear may sometimes proceed from within and be of purely psychic origin, in which case the external evidence is greatly modified and subdued, but the internal emotion is attended with marked mental dread or fear amounting to almost despair. In such cases the attention and imagination enormously augments its intensity and at times tortures the patient to such a degree that he loses control of himself and becomes almost mentally alienated during the paroxysms. Moreover, the emotion of fear under certain conditions proves stimulating, so that the frightened subject under its action seems to take on new strength and perform feats that would otherwise have been impossible without the unusual stimulus attending it. On the other hand, fear more often entirely overcomes the inhibitory power and renders the will powerless, so that all the vital functions are temporarily checked or held in abeyance. The emotion of fear may therefore be stimulating, inhibitory or paralyzing to the vital functions according as the stimulus is strong or weak and the reaction active or indifferent.

Fear is sometimes induced without any apparent cause and the subject of it may acknowledge this, yet they feel its influence as strongly as if the actual cause was known. The character of the stimuli producing them, however, is very various and corresponds to the conducting paths associated with the various senses.

Morbid fear, or pathophobia, comprehends almost as many varieties as there are diseases; for instance, one person fears that he has heart disease, another that his lungs are affected, a third that he has liver complaint, a fourth that his sexual organs are impotent—indeed, all the various functions and organs of the body may thus be attacked in the mind of the patient.

Students of medicine are especially prone to attacks during the early part of their college course, and from their reading treatises on pathology they arrive at the conclusion and become convinced that they are suffering from a certain disease.

These temporary attacks of morbid fear are, however, usually due to errors of diet, and can usually be effaced by appropriate means of treatment. As an element of nervous disease, however, morbid fear not only appears in a more serious aspect, but often becomes the most troublesome and difficult of all complications. More especially is this true of neurasthenia, in which affection it at times presents all its various phases. Indeed, we have good reason to believe that morbid fear, when presenting its more serious degrees, is an essential element of psychic neurasthenia. Unfortunately, there seems to be no unanimity of opinion as to what the term implies or signifies. Hence, we find it used synonymously with the term, imperative concept or idea, obsession, impulsion, besetment and fixed ideas. According to one authority, morbid fear is an emotional neurosis, a fixed or fleeting idea, which is the commencement of an impulsion or impulsive act. Another authority claims that "the subject of an irresistible impulse is the victim of an imperative concept or idea in the great number of cases, if not in all cases. These are described by various authors as imperative, dominant, automatic or fixed ideas, besetments or obsessions. They are lesions of the will very common among the insane, and far from uncommon in people who are not known to have any mental defect." Still another author states that "morbid fear is a fixed idea, anguishing, obscessive, that leads its victim to apprehend not only the attack of the malady, but even to suffer from it, so to speak; such is the power of auto-suggestion that the pathophobic patient can truly imagine that he feels the pain and even mimic the symptoms (to some extent at least) of the disease he fears he is suffering from." According to Tuke, "imperative ideas are morbid suggestions or ideas demanding notice, the patient being painfully conscious of their domination over his wish and will," a condition, as Dr. Angell[1] says, "very different from that produced by the fixed idea or delusion of the insane mind." In one case (imperative idea) the psychical reaction in feeling is against the idea; in the other (fixed idea) it is in harmony with it. "Gould's Dictionary" defines an obscession as an imperative idea, a dominant delusion or besetment. According to the French and German authors, the term obscession includes the idea of antagonism and thus more clearly than imperative idea defines the conscious struggle of the ego against its acceptance. The conscious and even painful resistance of the mind is an essential element in the condition. Therefore, the terms imperative idea and obscession are identical, both involving conscious resistance of the will. The consensus of opinion, therefore, strongly favors a real discrimination between an imperative idea or obscession on the one hand and a fixed idea or delusion on the other. Regis also recognizes a distinction between a fixed idea and an impulsion. According to this author, "the fixed idea is only the commencement of the impulsion and not actually identical with it." "As regards the impulsion itself, conscious and rational as it is in neurasthenia, it is a very complete syndrome, in which the unresistable act is only the last term of a morbid process of which the fixed idea is the starting point and the anxious emotion the intermediate stage." Morbid fear, however, when carried to an extreme degree, leads to impulsive acts. Admitting that technically these various terms can be strictly differentiated, all authorities agree that the difference is largely one of degree rather than of kind, and it is the degree combined with their persistency that indicates their true nature and character as well as seriousness. Moreover, all authorities agree in the main that morbid fear and its allied states are not only identical in their essence and character, but that they rarely exist singly, and are usually multiple or exist in combinations. The tendency, however, has been to create for each a special designation or name, but as they are simply the reproduction carried to a pathological extent of the ideas, sentiments or tendencies common to mankind there is no limit to their special manifestations. For all practical purposes they are recognized as having for their basis a presentiment of dread or fear which amounts to a more or less intense feeling of anxiety, which irresistibly forces itself upon the sufferer at times, dominating his every thought, word and deed.

Regis[2] has divided them into three classes, viz., 1, those characterized by indecision, of which all kinds of

1. Journal Nervous and Mental Diseases, August, 1900.
2. Manual Mental Medicine, p. 262.

morbid doubts are typic; 2, those characterized by all kinds of morbid fears; 3, those characterized by morbid propensities or irresistible tendencies. Each of these are again subdivided. For instance, "Ball" has divided the first class, or doubters, into five subdivisions, according to the nature of their predominating ideas. Hence we have: 1. "The metaphysicians, who are especially haunted by abstract questions of all kinds, such as doubts concerning heaven, hell, the world, the deity," etc. 2. "The realists, who constantly revolve in their thoughts the lower and base details of objects, such for example as the conformation of the genital organs, copulation," etc. 3. "The scrupulous, whose doubts pertain to forms of religion, such as accusing themselves of committing the unpardonable sin, or of some theft," etc. 4. "The counters, whose doubts are manifested under the form of irresistible enumeration." Such patients never get through counting different objects, such as doorknobs, the houses on the street, or their numbers, etc.

The second class, or those suffering from morbid fears or phobias, is divided into three subdivisions: 1. Those who have a morbid fear of all kinds of objects, or rupophobia. Its expression is extremely varied and may involve such articles as glass, knives, pins, guns, thunder, flowers, besides certain kinds of food and drink. 2. Those who have a morbid fear of places or elements; agoraphobia or disease, pathophobia. Such patients are morbidly fearful of high places, bridges, streets, churches, theaters, rivers; besides a dread of all kinds of diseases, such as heart disease, liver disease, cancer, syphilis, paralysis and insanity. 3. Those who have a morbid or irresistible propensity to steal, lie, cheat, drink, blaspheme, set on fire, abuse the sexual organs, homicide or suicide. This includes such conditions as kleptomania, dypsomania, pyromania, nymphomania, etc. All of these various states are ably shown by Regis to be due to lesions of the will, and are often associated with neurasthenia as well as insanity. In a limited degree they are commonly present in health; indeed, very few of us escape the presence of doubts, fears or impulses as isolated sudden thoughts, but which are controlled by the dominating power of inhibition. For instance, it is a common experience for persons looking from a height to be tempted to jump down, or in walking on the street are suddenly seized with a desire to count the houses or numbers on the doors, etc. These sudden impulses are easily resisted or controlled; but when they appear as a complication of nervous diseases they are often morbidly persistent and get beyond the control of the will. In their exaggerated forms they therefore constitute a serious symptom and may become the dominant feature of a grave form of insanity. In all cases, however, where their presence can be demonstrated, they are to be regarded as marks of true degeneracy, often remaining latent for years, to be brought to the surface by some sudden or severe shock to the nervous system, such as trauma, or severe mental and physical strains, beside excesses of all kinds. Moreover, there can be little doubt that certain crimes are due to such sudden impulses which arise in the minds of persons who are not ordinarily regarded as insane, and which the subjects are wholly unable to resist. Hence, they are truly irresponsible and should be given the benefit of the doubt.

Treatment.—If morbid fear and its allied states have for their underlying cause a faulty nervous organization involving both the physical and mental constitutions, it follows that their treatment must necessarily take cognizance of both mind and body. To accomplish this successfully it is essential that the physician be allowed the full care and control of the conduct and life of the patient. This, I believe, can best be done by isolation of the patient, and preferably away from his home. By removing the patient from his accustomed environment we do much to bring about a disassociation of the morbid ideas. As a rule the home life of the patient furnish the two extremes of indulgence and irritability, which proves a most fruitful soil for the cultivation and development of the etiologic factors underlying the morbid ideation. Isolation, if too prolonged, however, may defeat its own purpose by the patient becoming too readily accustomed to the new associations. A frequent change is therefore sometimes demanded and proves of great value in breaking up, as it were, the continuity of the morbid fear. Having isolated the patient we are then prepared to put in force another powerful therapeutic agent, viz., suggestion. When this agent is used aright it includes all the influences and possibilities of a strong and appropriate personality. Its judicious employment is even more difficult than isolation, tasking to the utmost the keen insight, knowledge, ingenuity, tact and judgment of the physician. In its essence it embraces all the influences included in the term hypnotism; for, the substance of this is none other than suggestion. Its successful practice depends entirely upon the physician's ability to influence the mind of the patient, and the first step in the process is to gain his full confidence, a task not always easy. Dr. Gray says: "It requires more tact and knowledge to play upon the mind than upon the finest piano that was ever constructed." Not all physicians can use this mighty power of suggestion with success, but with many it is one of the most powerful agents they have at their command. As the cultivation and development of morbid fear depends upon an abnormal psychical as well as physical organization, the psychical treatment to be effectual must be directed toward the dissolution of the pathologic mentalization and the substitution in its stead of a healthy mental process of ideation. For this purpose the peculiar mental traits and characteristics of the patient must be studied as well as the cause, nature and character of the morbid fear. This will also suggest the birth of the new or healthy idea to be established. The essential qualities of this newly acquired idea should embody the inspiring influences belonging to hope, progress and cooperation with sufficient force and power as to impress upon the mind of the patient the certainty of ultimate recovery. This plan, therefore, embodies an educational scheme, the special object of which is intended to restore to the will its normal control of the emotions and intellect, at the same time teach the patient to become more self-confident, self-dependent, and self-reliant, without which all methods of treatment prove futile. Oftentimes the revelation on the part of the patient of the nature of his morbid ideation or fear and its corresponding disturbance in consciousness will relieve the mental stress and cause it to fade away. In many cases it is necessary to take charge for a long time of the distempered mind, and by constant advice and oversight direct its activities into a normal and healthful channel. Sympathetic interest, tempered with wise counsel, will often do much toward its relief. To aid us in the accomplishment of the purpose set forth, the judicious use of massage, electricity, hydrotherapy, special diet and the use of drugs such as iron, quinin, strychnin, kola, bromids, hypnotics and stimulants are used with great advantage. More especially is electricity of great

service, one author preferring the faradic current, another the galvanic, and still a third the static form or franklinization. It is seldom, however, when this agent is used intelligently that we do not obtain, if not a cure, certainly a temporary and sometimes a lasting alleviation.

Measures that are directed toward the relief of the physical conditions associated with morbid fear pertain largely to the removal of the cause. If the general health is depressed or found suffering from any toxic condition such as lithemia, auto-infection and similar states, the use of the salicylates, alkalies and saline cathartics, with proper diet, are often attended with marked relief. In the practical therapeutic realm of neurology and psychiatry no symptom at times offers more obstinate resistance to all kinds of treatment than morbid fear; but in the majority of cases, if the principles referred to are intelligently, persistently and scientifically applied, much can be done towards its permanent alleviation.

In conclusion, I desire to acknowledge my indebtedness to the recent able articles by Dr. Thompson[3] of Vermont, and Dr. Angell[4] of Rochester, N. Y.

Altman Building.

TEN CASES OF INFECTIOUS MULTIPLE NEURITIS, WITH TWO DEATHS.*

W. A. JONES, M.D.

MINNEAPOLIS.

From the 15th of February to the 15th of March, 1901, there was an unusual series of cases of multiple neuritis in the city of Minneapolis. As near as I can learn there were probably from twelve to fourteen cases under observation, ten of which it was my fortune to see. This series includes the general types, but does not consider the forms of neuritis involving one extremity only, of which there were several.

The onset of the disease, as well as its occurrence at a time when influenza was epidemic and when other diseases of irregular type were prevalent in the city, suggests that the influenza bacillus was responsible for cases of neuritis, especially as six of the ten occurred within one week and three or four of the six within two days. During this period the number of deaths resulting from typhoid fever was greater than former health reports had shown. There was also an increased number of pneumonias and mild bronchial infections, as well as a large increase among the exanthematous diseases.

Case 1.—Miss N——, aged 27, domestic, family history good—the father, five brothers and six sisters living and well; the mother died at 67, of a chronic stomach disorder. The patient was ill at 17, and spent three successive summers at some hot springs in Norway. For the past seven years she has been well, except for occasional menstrual pains and constipation, with resultant headaches.

On the morning of March 10 she awoke with headache, general lameness and diminished power in all her extremities. She could not get up from the bed or a chair without great effort, but once on her feet she was able to go about and do the ordinary work of a cook. The grasp in both hands was feeble, and she was unable to lift more than two or three pounds; there was no loss of sensation; coördination was good; knee-jerks were preserved; there was no evident tenderness of nerve trunks. She made a practically complete recovery in three weeks without remaining in bed. At the end of five weeks she recovered her strength, and resumed her heavy work.

Case 2.—Mr. B——, aged 52, seen in consultation with Dr. F. A. Dunsmoor, February 20; mother and father living at advanced ages; one sister living, a nervous invalid. The patient is a tall, spare man, long of bone, but has a muscular system of great vigor. He is an esthetic neurotic, and suffers from headaches brought on by fatigue. He has always been an active and fairly successful business man. During the month of February he was under annoying business strain, but was as well as usual on the morning of February 17. During the day he felt unusually weak, walked with difficulty in the afternoon, and in the evening was unable to get about. The following morning he was decidedly weaker, and later in the day his arms and legs were practically helpless, yet he could feebly move his fingers and toes, flexion and extension being preserved. If placed on his feet and supported, he could walk short distances. At this time he complained of no pain, but experienced a tingling in the fingers and soles of the feet. He was not incoördinate, as far as could be demonstrated. The loss of power gradually increased until it completely involved all of the extremities. The knee-jerks were abolished. For ten days his condition was unchanged, except that he suffered pain in the calves of the legs, in the thighs and over the lower part of the back. There was no anesthesia, but rather a hyperesthesia of the toes and fingers. When an attempt was made to place him in a reclining-chair, he became cyanosed and exhibited a few general convulsive movements. His improvement dated from this time by a return of the smaller movements of the hands and feet. Although there was some atrophy of the interossei muscles, the muscles of his arms and legs were flabby. Improvement was rapid in spite of a partial reaction of degeneration. The extensor muscles of the back and thighs were the last to recover, as was shown by his inability to get out of bed or rise from a sitting position without the "climbing up" method of the progressive atrophies. He resumed his business May 1, ten weeks after the onset of the neuritis. His knee-jerks are present although not active, and he is able to walk several blocks, complaining only of fatigue and heaviness of his feet.

Case 3.—Mrs. McD——, widow, aged 40; occupation, nurse; seen by Dr. F. E. Strout, who referred her to me March 6, 1901. Her general physical condition was good in spite of years of hardship. She was moderately neurotic in appearance and history. She had been working very hard for four weeks before this illness, and was sleeping badly. On the morning of March 5 she awoke as well as usual. On attempting to rise from a chair she fell to the floor, but rose immediately without assistance. During the forenoon she complained of pains in the back, and down the legs. The following day there was diminished power in the hands and arms and a feeling of heaviness in the legs. She could stand and walk if placed on her feet. There was no Romberg sign; the knee-jerks were present and normal. She complained of a dulness of sensation on the outer side of the thighs and over a small area in the lower dorsal region. There was some difficulty in swallowing, coughing and sneezing; the breathing was decidedly diaphragmatic. All of these symptoms cleared up in three or four days, leaving no disturbance of sensation, and no respiratory incon-

* Read at the Fifty-second Annual Meeting of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Frederick Peterson, Hugh T. Patrick and H. A. Tomlinson.

veniences, although she could not elevate her tongue or maintain an upright position of the head and neck. On March 9 a facial paralysis appeared in the lower right face, and extended rapidly until it became bilateral, involving all of the muscles. On the next day a Babinski great toe phenomenon in the right foot was present. At no time was there a rise in temperature, or continued pain or tenderness of the nerve trunks.

The patient was confined to bed for four weeks, and although never absolutely helpless, she was unable to help herself in turning or moving. She began to improve in two weeks, and in six weeks was up and about with a limited extensor paralysis of the thighs and back. The paralysis of the left face cleared away in two months, and at the present time the paralysis on the right side is disappearing. Her general muscular strength is good, and she has resumed her work. The urine was examined occasionally, but contained no abnormal products.

Case 4.—Mrs. J——, aged 35; mother of two children. Her parents are living and in good health, although the mother is a neurotic. The patient also is a neurotic. An illness ten years ago, accompanied by pain in the back of the neck, confined her in bed for a month. Following this she was weak and tremulous in the extremities for nearly a year, but made a good recovery. In February, 1901, she had an attack of influenza of mild type. She made what she thought was a good recovery. At least she was able to attend to her household duties, which were unusually burdensome, but she admitted that the fatigue which followed was unnatural. I saw her March 10, in company with Dr. Strout, her attending physician.

She complained of pain in the back of the neck, behind both ears and down the sciatic nerves. There was diminished power in all the extremities, and an inability to turn the head and body from side to side, but she could stand upright if placed on her feet. There was also slight embarrassment in coughing, swallowing or sneezing. There was no loss of sensation, no marked tenderness over the nerve trunks after the first few days, and no rise in temperature. One week after the onset of the polyneuritis the left face became paralyzed, but this and the respiratory disturbances cleared away in ten days. The knee-jerks were abolished. She made rapid improvement, and is now able to go down town, and walks with ease. The right knee-jerk has returned, but the left is absent. The left leg is weaker than the right, and fatigue causes a tremor of the hands.

Case 5.—Miss L——, aged 33; seen in consultation with Dr. T. S. Roberts, March 8. The patient is of neurotic stock, and has a history of previous nervous attacks, simple and functional in character. About March 1 she complained of vague disturbances of sensation and power, and was sleepless and nervous. She apparently recovered in two or three days, thus suggesting that the attack was hysterical. On March 4 the symptoms returned, and with them a weakness of the extremities, back and thighs. She was unable to keep her head from falling forward or backward, and she could not rise from the bed or a chair, but could stand and walk if placed on her feet. There was also a transient difficulty of swallowing. On March 11 a bilateral paralysis of the face appeared. There were no disturbances of sensation, and no tenderness of the nerve trunks of importance. The knee-jerks were normal. She improved rapidly, and is now practically well, although there is still a tendency to fatigue on overexertion. The facial paralysis has disappeared.

Case 6.—Miss H——, aged 23; seen with Dr. H. K. Read April 3; a strong, healthy girl with a good family record. During the latter part of February and the early days of March, 1901, she was exposed to street draughts from the doors of a department store where she was employed. She complained of the usual symptoms of influenza, headaches, pain in the bones, cold hands, clumsy and awkward fingers. She could not execute quick or fine movements of the fingers, such as writing, tying parcels or adjusting box covers, neither could she stand on her toes or the ball of the foot in reaching shelves. The diminished muscular power increased until all the muscles of the arms supplied by the brachial plexus, except those supplied by the musculocutaneous nerve, were involved. Power in the legs also diminished until the patient was practically helpless, but she could walk if placed upright. There was no disturbance of sensation. The deep reflexes were decidedly diminished, and partial reaction of degeneration was present. After four weeks there was some muscular atrophy in the hands and legs. At this writing she has gained rapidly, particularly in the right arm, the left arm being still weak and its movements limited. She can go up and down stairs with but little assistance, but she can not rise from a sitting position. There was slight tenderness over the nerve trunks.

Case 7.—Mrs. G——, aged 22; seen in consultation with Dr. Matchan March 14; a decided neurotic of neurotic history and parentage; has never been seriously ill before. During the early part of February, 1901, her menses had ceased, and she sought and gained relief through the kind offices of an abortionist. The menses appeared February 27. Three days later, after becoming chilled, she noticed that her wrists and hands were weak. She was unable to pick up small articles or to execute fine movements. The following day her arms grew worse, and in attempting to get up from a chair she fell to the floor. The loss of power became complete in all extremities on the third day, and was associated with a left facial paralysis and a difficulty in swallowing, coughing and sneezing. Abdominal respiration was present, and there was a paralysis of the muscles of the neck supplied by the cervical plexus. She complained of grinding, aching pains, but there was no loss of sensation, and no bladder or rectal disturbance. There was marked tenderness over the nerve trunks and muscles. It was difficult to estimate the amount of pain and tenderness, as the patient was decidedly hysterical; yet I believe there was some pain. There was an occasional rise in temperature, which was probably due to incidental conditions rather than to the neuritis. The facial paralysis and the respiratory distress disappeared in about one week. I saw her March ——. She had slightly improved, and can now raise and lower her hands and use both arms, although recovery of the left is not as far advanced as in the right. She can elevate her trunk, and can extend and flex the toes and feet. There is atrophy of all of the muscles in the four extremities, and reaction of degeneration is still present.

Case 8.—Mr. S——, married, aged 37, Burbank, Minn. I saw him in consultation April 7, with Dr. Alex. Ridgway and Dr. Christian Johnson, the latter of whom reported the case in detail in the *Northwestern Lancet* for May 1, 1901. The patient is an active, nervous man, in good health usually, except for slight attacks of muscular rheumatism after severe labor and exposure. The parents were of nervous temperament.

About the middle of February, after working hard on his farm, he came to Minneapolis, from which place he

drove to his home, a distance of one hundred miles. The weather was severe, and he suffered from exposure. On February 27 he had a "splitting headache," and in the evening was exhausted. On the following morning, February 28, after working a short time, his legs became weak, and his power in the arms diminished. On March 1 he was unable to get up or dress himself. The evening of the same day he was completely helpless; his breathing was labored and wholly abdominal; there was severe pain and tenderness over the plexus and nerve trunks, with paresthesia. Tactile sensation is preserved and areas of hyperesthesia and thermohyperesthesia are present, but no anesthesia. The reaction of degeneration is marked in practically all of the muscles, and the knee-jerks are abolished. The bladder and rectum are not involved in the paralysis, and there has been no rise in temperature or pulse.

At this time, June 1, Dr. Johnson writes me that the patient has recovered motion in the trunk muscles, the biceps of the left arm and the right extensor femoris, as well as slight motion in some of all of the regions involved. The patellar reflexes are nearly normal.

The following two cases are of an apoplectic type, and so rapid was the onset and progress of the disease that the diagnosis may be questioned; they were among the first cases seen. I did not make a diagnosis until later, after a study of the milder forms.

Case 9.—Miss S——, aged 26, bookkeeper; seen in consultation with Dr. W. A. Hall March 4; family and personal history good; typhoid six years ago, from which she fully recovered; has worked steadily for years, but has been well. On the afternoon of March 3, she spoke of a soreness and stiffness between the shoulders, but continued her work until evening. At 7 p. m. there was a rapid loss of power in the right hand and arm. At 3 a. m. the following day she wakened, and found both arms powerless. She became alarmed and sent for her physician. Later in the morning she lost power in the legs; there was embarrassment in coughing and swallowing, and the breathing was abdominal. At noon she was moved to the hospital, and soon afterward had a temperature of 100° F. As there had been no rise in temperature before, it is probable the rise was due to the journey. At no time was there pain, disturbance of sensation or tenderness of the nerve trunks. When I saw her, forty hours after the onset of the disease, she was unable to speak above a whisper, could breathe only with the head lowered, and was unable to swallow. The saliva accumulated in the mouth to such an extent as to require constant removal by cotton plungers. During the same afternoon she became cyanosed, but was temporarily revived by oxygen inhalations. She grew worse rapidly, however, and died at midnight, having lived less than sixty hours from the onset of the disease.

Case 10.—Mrs. McN——, aged 40; patient of Dr. E. S. Kelly; a person of large frame and overfat, but with a good personal, and a negative ancestral, history. During February, 1901, she had an attack of influenza, accompanied by fever and pains of moderate severity. She recovered in ten days. On March 4, in the evening, she had a paresis of the right hand and arm, which disappeared in a few hours. The following day, or twenty-four hours later, there was a return of the paresis in the right arm, and a partial loss of power in the left leg. The third day all extremities were helpless, except slight movements of flexion in the fingers and toes; the breathing was diaphragmatic, and swallowing was difficult. There was no loss of sensation, and no pain. Death occurred on March 7, three days after the onset of disease.

I regret that no autopsy was permitted in either of these cases, although I am convinced that they were fulminating forms of multiple neuritis.

Contrast these cases with the ordinary types of polyneuritis due to overwork and exposure, and secondary infection, with a weakness beginning in one extremity, gradually extending, and accompanied by marked tenderness and severe pains, anesthesias, changes in the skin and nails, atrophy of muscles, prolonged paralysis and slow repair. One or two of the cases cited correspond to the usual descriptions found in the text-books. The majority, however, are not typical, as is shown by the prominence of the motor symptom; the ability to stand and walk, even though the patient is unable to rise from the recumbent or sitting position; the frequent absences of trunk pains, tenderness, paresthesia and anesthesia; the evident involvement of the cervical plexus, as demonstrated by the inability to control the muscles of the neck and the implication of the phrenic nerve; the minimum muscular atrophy and the rapid improvement in most of the cases.

Many of these cases, notably the two that were fatal, and a few of the others in which the typical pains, anesthesia and tenderness were not present, suggest Landry's paralysis, and yet is it not probable that many of the cases reported as Landry's paralysis are cases of multiple neuritis, in which the infection or inflammation of the nerves of the extremities extends to the sacral, lumbar, brachial and cervical plexus, and from there to the roots of the cranial nerves? If the patient dies within a few days, the presumption seems clear that death is due to the implication of the vagus; should he live for weeks or months it is fair to presume that the degeneration of the nerve trunk extends beyond its superficial origin, to the cells from which it springs.

Rowden, in the *Lancet* (London), recently reported a case of Landry's paralysis in a child, in which the symptoms began by a progressive, symmetrical motor paralysis of the neck, arms, forearms, chest and legs; with the sensation not involved until within a few hours before death, and then only slightly; with no rigidity, twitching, pain or spasm; and with the mental functions unimpaired and no bladder or rectal disturbance. Although this case is supposed to be one of descending type, I believe it could more wisely be classed as multiple neuritis.

The treatment of the foregoing cases was mainly symptomatic. Free elimination was established, salicylate of soda in full doses was given; strychnia and iron, to overcome the anemia which was marked in all of the more profound cases. Faradism, massage, salt baths and forced feeding completed the care and treatment.

DISCUSSION.

Dr. Hugh T. Patrick, Chicago—Such a remarkable series of cases should not be allowed to pass without comment. The idea suggested to me primarily by the paper was the close similarity of the symptoms in some of these cases to the disease known as Landry's paralysis and to inferior encephalitis. Although the discovery of the neuron as a histological entity has added nothing to our knowledge of the physiology and pathology of the nervous system, I think it is sometimes of value as an aid in the expression of our ideas on these subjects. When a motor neuron is affected by a certain poison, it is reasonable to suppose that the motor cell, with its long process, the motor nerve fiber, is acted upon as a whole. In the cases reported by Dr. Jones it is reasonable to suppose that those individuals, or their motor neurons, were particularly susceptible to the poison of influenza, and that such poisoning would

be very apt to cause symptoms which could be partly explained upon the theory of peripheral disease and partly upon that of central or nuclear disease. Probably a combination of the two was present. The term multiple neuritis is convenient, but I regard it as a misnomer. Certain neurons are peculiarly susceptible or vulnerable to the action of certain poisons, and the poison in Dr. Jones' cases must have particularly affected certain parts of the motor system. The process is one of poisoning, not inflammation at all. I have seen three cases, one of them being still under observation, which I think showed very graphically the intimate relationship between this peripheral nerve degeneration and the acute nuclear affections. Two of my cases, which came to autopsy, presented the symptom of weakness of the lower face, neck and shoulders, with some impairment of power in the arm, but with very little involvement of any motor structures below the shoulders and no sensory disturbance to speak of. In one of the cases, I have thus far examined 800 sections from the medulla and pons; they show nothing but what could be interpreted as the result of an intoxication acting upon the nervous structures. I think we would be better able to understand the so-called acute multiple nuclear affections, Landry's paralysis and myasthenia gravis, if we looked upon them as forms of intoxication having an affinity for the neurons of certain individuals or, as I think it is better expressed, toxic paralyses due to the peculiar susceptibility of certain neurons to certain poisons.

DR. HAROLD N. MOYER, Chicago—In continuation of Dr. Patrick's remarks, I would emphasize the conception of the neuron as applied to this class of lesions. It is sometimes impossible to distinguish between peripheral and nuclear lesion. In the cases which we have just heard reported I think some were peripheral while others were nuclear. A pure peripheral lesion is really one that is extra-nervous in its origin. The nerves are liable to the same conditions as are other organs. For example, they may be the seat of cloudy swelling and exudate, with edema in the sheath and consequent pressure symptoms. That, to my mind, is a clear conception of a peripheral nerve lesion. With a nuclear lesion the body of the cell is involved, including the neuro-axon.

DR. W. A. JONES, in reply—I agree with Dr. Patrick that multiple neuritis is not a very good name for the disease under discussion—that intoxication neuritis or infection neuritis is perhaps better. My belief is that the more profound infections of this type are associated very soon with a central lesion, and yet some of these cases, although comparatively severe, showed a remarkable and rapid recovery. One or two of my cases have recovered completely, and the rest have so far recovered that we may call them practically cured. Those cases, I think, were not of central origin. The axis cylinder or the outside of the neuron was probably only partially implicated and the repair was very rapid. It seemed to me that those cases which resembled Landry's paralysis illustrated the uncertainty of Landry's pathology, and I think we should classify them under one general head and not attempt to divide them into different types.

THE INCREASING STERILITY OF AMERICAN WOMEN.

GEORGE J. ENGELMANN, M.D.

BOSTON, MASS.

CORRECTION OF DIVORCE STATISTICS.

In my recent paper on *Sterility*[1] I have introduced the subject of *divorce* as one of the factors correlated with sterility and parallel with it in a general way. In reviewing the article at my leisure I find some very palpable statistical errors in my discussion of this subject, and whilst the result remains the same and the subject is in itself of no especial interest to the profession, these errors must be promptly remedied lest they lead to farther mistakes and entanglements. Divorce records are believed by statisticians to fall far short of scientific accuracy, and in collating these uncertain data I have repeatedly placed incompatible figures side by side (Table 4 of this paper) comparing the ratio of *"divorces to marriages"* with that of *"divorced to the married;"* the relative proportion in the different states and countries is practically the same, but this is incidental and the error of such comparison is so patent that it must *apparently invalidate all that has been said; actually nothing is altered* as far as the increase of divorce and my comparison between divorce and sterility among different groups is concerned; nevertheless, I desire to correct the error by recalling all statistical data on divorce contained in my recent paper and will here present the correct figures and comparisons.

In that admirable work on "Marriage and Divorce," Carroll D. Wright* says: "It has been exceedingly difficult to arrive at a reasonable, legitimate conclusion for a comparison between divorces granted and some other condition or status . . . the comparisons made in a few states between marriages celebrated and divorces granted is worth simply what it has been given for, but it is essential for a just consideration of the whole matter that a comparison should be made between the married couples existing and the divorces granted." This I have done, and in addition I have presented the ratio between divorces granted and marriages performed in the same year (Rhode Island), and also the ratio between divorced persons and married persons, using whichever seemed to serve the purpose best. Approximately the same errors must occur by use of the same method in different states and among different classes of our population, so that regardless of the precise accuracy of the data the *relative values* and the *relative ratio of increase or decrease* can not be questioned.

CORRECTED TABLE IV.—DIVORCE.

A.—RATIO OF DIVORCES TO MARRIAGES.[1]

	Registration Year.			No. of Divorces to 100,000 Marriages.	No. of Marriages to One Divorce.

1897	3137	372	8.4:1
1898	3278	400	8.2:1

The sixth paragraph after Table 4 in the original paper presents correctly the relative frequency of divorce among the various groups of our population and strikingly shows the parallelism between divorce and sterility. But, strictly speaking, the figures indicate *not the ratio of divorce,* but the proportion of *divorced to married* persons, highest among *negroes,* 0.67 per cent.; next among *native Americans,* 0.61 per cent.; less among *Americans of foreign parentage,* 0.5 per cent., and least of all among *foreigners,* 0.3 per cent.

Whilst this does not accurately represent the ratio of divorces to marriages, as stated in the paper, it does practically and it likewise represents the relation of these groups toward each other as far as sterility and miscarriage are concerned, and inversely their relative position as to fecundity.

No words of mine can more clearly indicate the correlation of the factors named than does the proportion of divorced to married among these groups and to demonstrate this parallelism I have introduced the subject of divorce; to this extent it is of interest to the medical observer, and I have desired to place the facts correctly before the profession, fearing that the comparison of incongruous elements originally made must necessarily prejudice the reader against any deductions therefrom.

As sterility has increased, so has divorce, and we see this demonstrated whether we compare the ratios of divorce to marriage in earlier or in recent years; this increase is well shown in Table 4, Part C, and I have selected Rhode Island because the vital statistics of this state in many respects, especially in all that relates to marriage and divorce, are more carefully kept than is customary in this country. The data given must be taken for what they are worth; absolute precision can not be claimed, but they do positively show what even the faulty tables of my original paper indicated, the same steady increase in the ratio of divorce as in that of sterility and the noteworthy parallelism of both.

208 Beacon St.

APPENDICECTOMY—SURGICAL HISTORY. (1758-1888).

B. MERRILL RICKETTS, Ph.B., M.D.
CINCINNATI, OHIO

Mestivier, in 1758, was the first to record a case of lesion of the appendix. Eight years later, in 1766, De La Motte refers to a case which he found on making an autopsy. Laennec, in 1803, by his studies on the peritoneum made some headway. But no one seemed to have remarked the significance of his discoveries. In 1824 Lonyer-Wildermay reported a fatal case of peritonitis and gave the perforation of the vermiform appendix as the cause. Husson and Dance, in 1827, gave a detailed description of the diseases of the cecum. Both Lonyer-Wildermay and Melier believed that the diseases of the cecum and appendix were separate and distinct. Melier, in 1827, reported four cases, three of which were perforations of the appendix with fulminating peritonitis. He considered the causes, character and consequences of appendicitis; he even anticipated the possible advantages of operation. He says: "If it were possible to establish, with certainty, the diagnosis of this affection we could see the possibility of curing the patient by an operation. We shall some day perhaps arrive at this result." Ferrall, in 1831, gave it as his opinion that phlegmonous tumors were not principally due to the appendix or peritoneum, but to the retro-cecal connective tissue. But it is due to Dupuytren that the doctrine of the cecum was so long held. In his writings (about 1833) no mention of the appendix in this connection is made. Copeland, in 1834, was the first to claim that the appendix may be the primary cause of serious trouble.

Burne, 1837, made a clinical distinction between the cecum and appendix; but he agreed with his contemporaries that the cecum was the prime cause of the trouble of the right iliac fossa. In 1839 he changed about and claimed that the cecum played but a minor part in causing disease. Albers also caught a gleam of truth. From this time on many cases have been reported showing the important part played by the appendix vermiformis in disease. Grisolle, 1839, made mention of a case of gangrene of the appendix, as did also Berard in 1840, who reported a case of gangrene of the appendix; death resulted from partial peritonitis. The crural artery was found to be obliterated. Becqueral, 1841, reported a case of lumbrocoids found in the peritoneal cavity, having come from a perforation of the appendix. A case of death from a similar cause is recorded in the *Transylvania Medical Journal* in 1849. In the *Quarterly Journal of Medicine and Surgery,* 1843, there appeared an account of a man who died at the age of 88, whose appendix vermiformis was found to contain 122 robin shot. During life this man never had any symptoms indicating disease of this organ. It appears that he was excessively fond of game, and that the shot found in the appendix was supposed to have been contained in the game. Dr. Willard Parker seems to have been among the first, if not the very first, to realize that an operation was necessary in cases where the appendix was affected. He believed the earlier the operation was performed the greater the chances for recovery. His first case was in 1843. He simply made an incision and evacuated the cavity. This was not reported, however, until 1867. Nelson, 1846, reported a case of inflammation of the appendix vermiformis from gallstones lodging in it. Hancock,[3] in 1848, described a case he cured by operation. Thurman[4] about the same time (1848) reported a case of hernia and enlargement of the vermiform appendix with fecal abscess and fistula; the patient made a complete recovery after discharging a small piece of bone. The same year saw the publication of Shaw's[5] case of hernia of the vermiform appendix. Alford, in 1854, was probably the first man to make a primary operation for appendicitis. He was followed by Howe, in 1860. Elliot,[8] in 1859, reported a case of ovarian tumor with ulceration of the appendix vermiformis. Gerlach's[7] publication, in 1859, cleared up the darkness that for years had gathered around this subject. Pepper,[10] in 1867, reported a case of healing from perforation of the appendix; but in process of healing, the appendix had been converted into a fibrous cord. In 1873, Bontecou[11] reported three cases of abscess and pelvic peritonitis

1. From Registration Reports or Vital Statistics of the various States, collected by Rev. S. W. Dike.

2. Figures originally presented by Prof. Wilcox, of Cornell, reproduced in the Victorian Year Book, 1894, and the Registration Report of Michigan, 1894, with additions by Dr. Wilbur, of Lansing; to these I have added the number of married couples to one divorce in order to present a means of comparison between the ratio of divorces granted to married couples existing in a given year, and of divorces granted to marriages celebrated in the same year.

from perforation of the appendix vermiformis, relieved by operation. In one case the cavity of the abscess was evacuated through an incision. Five days later typhoid fever set in, and the patient died. Autopsy developed a perforation of the intestine; the appendix was adherent, but, otherwise, indicated a perfect recovery. In another case he aspirated the abscess before making an incision. He claims that this use of the aspirator gave certainty to the diagnosis and enabled the operator to make a bolder use of the knife. Dr. Bontecou did not excise the appendix in any of his cases. After evacuating the pus he injected the cavity daily with a solution of carbolic acid. He says: "I have seen but few cases recover, and those were treated at an early stage by leeching, poulticing and opium given in some form in decided doses, and by physiological rest to the bowels." These were his conclusions after having had twenty cases. He agreed with Dr. Parker as to the advisability of an early operation. Bontecou appears to be the first to observe and record the association of appendicitis and typhoid fever. F. R. Noyes[12] reported in 1875 a death from a raisin seed in the appendix. Gouley,[13] 1875, reported a case of perityphlitic abscess due to perforation of the appendix. The patient had also an inguinal hernia. The abdomen was incised to the seat of the abscess. The cavity was cleaned out and packed with lint. The patient recovered and had no more trouble from the hernia. The patient in this case had swallowed a broken tooth two years previous to this attack, but no signs of the tooth were found during the operation. Mason, 1876, reported a case of perityphlitis with perforation of the appendix; he decided to operate. After benumbing the skin with ice he introduced a No. 3 trocar attached to the aspirator and then passed a bistoury alongside the trocar. The patient seemed to do well for several days after the operation, but then began to sink and died 74 days after the operation. A partial autopsy revealed a perforation near the junction of the appendix and caput coli. The wall of the abscess surrounded and bound down the caput coli and appendix. Sanns, 1880, aspirated an abscess supposed to be appendiceal. Noyes, in 1883, collected 100 cases in which an operation had been performed; 90 of these were in the United States. Barlow and Godlee[16] made, Sept. 16, 1885, an exploratory operation to determine the cause of an abscess in the right iliac fossa. Pus was found about the appendix, which proved to be the seat of the disease. The pus was evacuated, but the appendix was not removed. Hall,[17] on May 8, 1886, at 11 p. m., in operating upon a case in which he had diagnosed strangulated hernia, opened what he supposed to be a hernial sac of the scrotum, found the vermiform appendix, which he removed, enclosed in exudates and extensively swollen until it resembled a normal testicle in size and shape. An existing perforation was supposed to be due to tuberculosis, which was far advanced. H. B. Sands,[18] on Dec. 30, 1887, diagnosed a case as acute septic peritonitis caused by perforation of the vermiform appendix. He opened the abdomen and evacuated a pus cavity, trimmed the margins of the perforation off in the appendix and sutured them with silk. The appendix in this case was not excised. McBurney,[19] on May 23, 1888, removed the appendix in a case in which Dr. W. K. Otis had diagnosed appendicitis. This is the first case in which an operator deliberately planned for and did remove a diseased appendix. Lister's great discovery of the principle of asepsis gave surgeons great encouragement to interfere in cases that had been previously thought hopeless. Then it remained for the magic hand of Lawson Tait to perfect appendicectomy as he has all other operations upon the abdominal viscera.

Clinical Reports.

INTRACRANIAL RESECTION OF THE SECOND AND THIRD BRANCHES OF THE FIFTH NERVE

FOR THE CURE OF NEURALGIA, FOLLOWED BY PARALYSIS OF THE FACIAL NERVE.

LEO NEWMARK, M.D., SAN FRANCISCO, PROFESSOR OF NEUROLOGY, UNIVERSITY OF CALIFORNIA; and

HARRY M. SHERMAN, A.M., M.D., SAN FRANCISCO, PROFESSOR OF SURGERY, UNIVERSITY OF CALIFORNIA.

HISTORY OF THE CASE—By Dr. Newmark.

The patient, who is now 59 years old, had been suffering from neuralgia in the right side of the face for several years, and had undergone much medical and surgical treatment elsewhere before he applied to me for relief in 1897. His pain was chiefly in the area of distribution of the third branch of the trigeminal nerve. Five years before, an operation had been performed on his right lower jaw and had afforded him some alleviation; a second operation two years after the first was of no avail.

His pain raged in the lower jaw and shot into the tongue. He was repaid for even most cautious attempts to take food with paroxysms of pain; he could not swallow his saliva without enduring agony; also, his sleep was seriously disturbed by his sufferings.

There was an area of diminished sensibility to touch on the right half of the chin and lower lip, a consequence of the section of the mandibular nerve which had been previously practiced. To cold and heat also this area, as well as an adjoining part of the cheek, presented a reduction of sensibility. A gentle touch applied to a point on the right side of the lower lip or to one in front of the auditory meatus would provoke an attack of pain. The paroxysms were attended with twitching of the muscles on the affected side of the face.

The sensitive points were cocainized, and while they remained insensible, paroxysms were not excited from them. This procedure, however, although often repeated, did not benefit the patient materially. Numerous other measures were tried; also many drugs and applications of electricity.

As some writer having alleged that he had once cured trigeminal neuralgia by unremittingly passing a galvanic current through the head for about an hour, this tedious remedy was patiently essayed. Such efforts having been unsuccessful, surgical treatment was indicated. Two peripheral operations had been done in vain. The implication of the tongue showed that the trunk of the third branch of the nerve at least would have to be severed; and an occasional irradiation of the pain into the area supplied by the second branch, made it appear advisable to proceed even more radically. The extirpation of the Gasserian ganglion was accordingly suggested as offering the best prospects of permanent relief. This operation was undertaken on Sept. 8, 1897.

MEMORANDUM OF THE OPERATION--By Dr. Sherman.

The operation was that called the Hartley-Krause. The opening in the skull was made by chiseling. The exposure of the second and third branches of the trigeminus was uneventfully accomplished. A small nick had been unintentionally made in the dura, and the loss of cerebrospinal fluid through this permitted the dura to collapse somewhat and gave easier access to the nerves. The only disadvantage was the need of pretty constant sponging.

The nerves were cut at their foramina of exit and pulled from the ganglion. The third branch brought a portion of the ganglion with it; the second broke close to the ganglion. No attempt was made to get the first branch. The opening in the dura was sutured, and the wound closed by replacing the flap, less the bone. Healing was aseptic.

In view of the resultant facial paralysis, it is pertinent to state here that at no time during the operation was any tissue handled roughly, nor was any tissue cut beyond those specified in the descriptions of the operation. The flap was, of course, folded down over the zygoma, but no pressure was made by this on the facial nerve, nor could it have been so made; and the assistant who held this flap, Dr. S. J. Hunkin, is positive that no pressure was so made. Moreover, the integument in front of the ear did not show any abrasion or contusion after the operation.

At present (August, 1901), there is quite a depression above the zygoma, and that process itself is prominent. The scar up in the hair is linear. The right eye is constantly open, and the lower lid is semi-everted; the natural wrinkles and folds are absent, and the cheek flops. He loses some food and more drink out of the corner of the mouth. He describes to me his general condition as being better than it was three and a half years ago. He is a laboring man and is able to do light odd jobs.

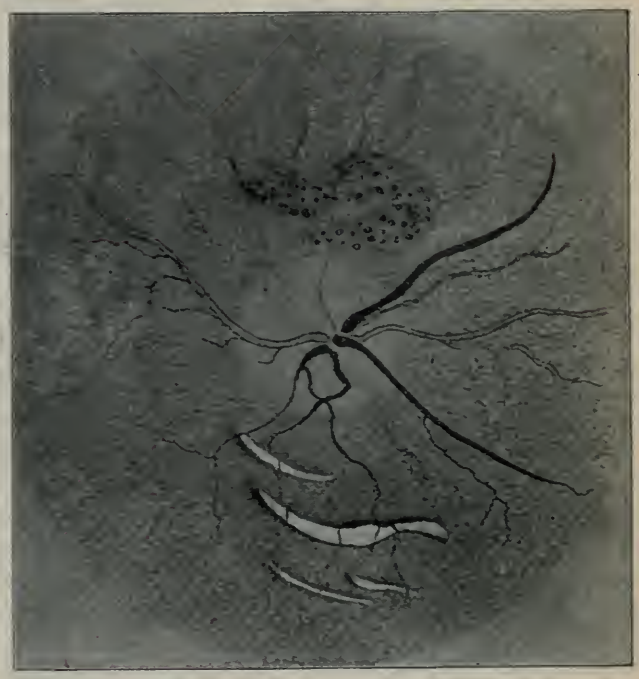
MEMORANDUM OF THE RESULT—By Dr. Newmark.

When the patient recovered from the anesthetic, he was free from pain, and on Jan. 9, 1901, he declared that he had not suffered since. But there is an alloy to the satisfaction at this result. After the operation, it was observed that the right side of the patient's face was completely paralyzed, all the branches of the facial nerve being involved, and the paralysis has not abated a whit.

The anesthesia resulting from the section of the trigeminal branches occupied the areas of the second and third branches of the fifth nerve in the right side of the face, and in the right half of the mucosa of the tongue, cheek, and hard and soft palate. At first the mucosa of the right nasal passage and the right half of the tip of the nose seemed slightly affected in regard to sensibility, but this was not observed a few days later. Taste was abolished on the anterior two-thirds of the right half of the tongue. The muscles supplied by the third branch of the trigeminal were, and are, paralyzed.

The anesthesia has diminished in degree in the course of the years that have elapsed since the last operation; but it has not appreciably receded. In the supra-orbital region, especially, it is less profound than formerly. In the temporal region the sensibility to cold is affected more than touch. Pin-pricks provoke pain throughout the affected area, even on the chin where sensation is most diminished. The patient says he does not feel his food when it lodges in the right side of his mouth, and investigation reveals the same condition of sensibility in the buccal mucosa as existed there three years ago. He also says that when being shaved he distinctly feels the scraping of the razor on the cheek.

We have found it impossible to explain why the facial nerve became paralyzed.



MULTIPLE RUPTURE OF THE CHOROID.*

J. WHITEFIELD SMITH, M.D.

Lecturer on Physiology and Hygiene, Illinois Wesleyan University; Oculist and Aurist, Chicago and Alton Railroad Company.

BLOOMINGTON, ILLINOIS.

Johnny T., aged 11, while playing ball, Sept. 30, 1901, about 2:30 p. m., was struck in the left eye by a small hard rubber-ball. His playmate threw the ball at a distance of 25 or 30 feet. The blow was of sufficient force to knock the patient to the ground. Patient became sick, turned pale, and vomited three or four times; sickness lasted until 5 p. m., after which time he became drowsy. Vision of injured eye was entirely lost at time of accident. On October 1 pupil was dilated, some pain and tenderness on gentle pressure; he could see a little better than the day before. On October 2 he consulted me; vision was not so distinct as on the previous day; he

could see only the shadow of a hand passed before the eye. Pupil was dilated, long axis in 60th meridian. Tension was lowered. Ophthalmoscopic examination showed the fundus to be clouded and the sight of the lesion obscured from view. After two or three days more the lesion could be definitely outlined, which is shown in the accompanying cut. Patient's vision at the end of the 5th week was 1-3. On the temporal side of the eye, in the illustration, are shown four crescentic or sickle-shaped rents in the choroid. The white streak is the sclera. The margins of the crescents, especially the largest one, are discolored, due to disturbance of the pigment. The retinal vessels pass over the site of the lesions, which show that there is no rupture in the retina.

On the other side of the papilla, beginning near its margin, is a peculiarly shaped area showing changes in the pigment of this portion of the fundus.

* Reported to the McLean County Medical Society, Nov. 7, 1901.

Meteorologic Factors in Dissemination of the Plague.—Rosanoff publishes a historical study of the plague in *Botkine's Gazette*, in which he endeavors to establish a causal connection between the dissemination of the plague and the prevailing winds.

SELF-DIGESTION OF TISSUES.

If the liver of a healthy animal is removed under aseptic precautions and so preserved as to exclude bacterial action, it will be found that after a considerable time, from a few weeks to a few months, the tissue softens and disintegrates. Examination of the residue shows that it contains in large amounts substances that are associated with the results of digestive processes, such as leucin and tyrosin, in earlier stages albumoses. Attention was first directed to this phenomenon of self-digestion, or *autolysis,* by Salkowski. As will be observed the products of digestion are analogous to those obtained by trypsin digestion, as characterized by leucin and tyrosin, rather than those resulting from pepsin action. Other observers, however, have shown that this latter ferment is present in the tissues normally, notably in muscles, but under ordinary circumstances the alkalinity of the tissues prevents the pepsin from producing any changes.

Martin Jacoby[1] followed up this work and showed that self-digestion was a perfectly normal and constant property of tissues during life. It is by no means limited to the liver; apparently it occurs likewise in all functionating cells. However, during life the products of the self-digestion are removed by the circulatory fluids as they are formed, so that they do not collect as in dead organs, hence are less prominent. In these columns attention was recently called to the part played by fat-splitting ferments within the tissue cells in fat metabolism.[2] Quite probably an altogether similar set of ferment activities accomplishes proteid metabolism. However, for lipase a reversible action has been shown, so that it is quite clear how the fat is split into diffusible substances that enter the cell and there recombined under the influence of the same ferment. As yet we lack proof that enzymes which decompose proteids can also build them up, but there is every reason to believe that such is the case. Granting this, our knowledge of proteid metabolism is as clear as it now is concerning fat, and we may consider that the enzyme present in the tissue cells is continually acting to combine digestion products into proteids, and to break the proteids down again as necessary to establish chemical equilibrium. These steps we see completely in intestinal digestion and absorption of proteids. Within the intestinal canal proteid is split up by trypsin. As the absorbed products of the splitting can not be found in the blood leaving the intestines they are evidently recombined in the walls of the intestine. Here is a complete analogy with fat absorption pointing decidedly to a reversible action of the trypsin.

Auto-digestion undoubtedly plays a prominent part in pathological processes, *e. g.,* the absorption of necrotic tissue. Petry[3] has demonstrated autolysis in a carcinoma of the breast, and the disintegration and softening within tumors is well known. Because of the similarity in the accumulation of leucin and tyrosin in acute yellow atrophy of the liver, and in phosphorous poisoning, with the results of auto-digestion Jacoby thought that here might be a direct explanation of the processes of this obscure disease. He experimented and found that phosphorous poisoning did increase autolytic processes markedly, but he did not particularly clarify the situation.

Conradi[4] has found that the products of autolysis have a decided bactericidal effect, probably due to certain of the aromatic groups derived from proteid. This may be of some importance, particularly as a possible explanation of the difference in susceptibility of certain organs to certain infections, *e. g.,* muscle and tuberculosis.

PROPHYLAXIS OF VENEREAL DISEASE.

The report of the committee appointed by the Medical Society of the County of New York to suggest methods for the prophylaxis of venereal disease is an interesting document. It was presented in abstract at the last meeting, November 25, of the Society, and we are enabled to give its salient points by anticipation. Each of the usually suggested methods for the repression of prostitution and its inevitable consequences is discussed, and the preventive measures that can be applied with promise of success, considering the ethical temper of our people, are especially dwelt on. The committee has not been led into impracticabilities, either by the difficulty of the subject or by the urgent need for action that is felt by every medical man who considers seriously the dangers to public health at present pharisaically overlooked.

The committee, in this investigation, shows that at least 150,000 cases of venereal disease were under treatment in the borough of Manhattan during the year 1900. These statistics emphatically point out the dangers to public health from this too commonly ignored source. As to methods of limitation and suppression, the committee is very frank. Legal regulation of prostitution seems inadvisable, not only because of the opposition that any question of even qualified toleration of vice arouses among English-speaking people, but especially because all methods of legal regulation hitherto attempted have proved failures. The general trend of the sentiment of specialists against this form of attempted limitation of venereal disease was very evi-

dent at the International Congress for Venereal Diseases, held at Brussels two years ago.

Segregation of prostitutes in one part of the city smacks too much of quasi authorization, or at least toleration, of vice to be well borne by our people. On the other hand, the committee considers that domiciliary segregation is not only advisable but absolutely necessary. Immoral persons must not under any circumstances be allowed to live in the same house with those who lead moral lives. Especially where there are families with children. prostitutes must not be allowed to ply their trade. To accomplish the much-desired end no new legislation is needed, but only the judicious and not too stringent enforcement of existing laws. All external signs of prostitution must be suppressed. Significant red lights, red curtains and the like, street soliciting, window tapping, etc., must be effectually done away with.

The most important prophylactic measure that medical men can bring about is the education of the public with regard to risks of venereal diseases and the difficulty and uncertainty of their cure. High schools and colleges should be advised to give special instruction with regard to the dangers of venereal disease. Family physicians should express themselves candidly, and young men should be told that sexual indulgence is not necessary to health and may involve serious infection with enduring disease. The transmission of syphilis should be made a penal offense. The statute could not often be enforced, but at times it would inflict deserved punishment, and its presence on the statute book would of itself be a striking educational measure. Because of recent revelations in the social conditions in New York City with regard to procurement for prostitution, the committee advises legislation raising the age of consent and the enactment of severer punishment for procurers.

The committee considers the powers at present conferred upon the City Board of Health are sufficient to enable that body to take due measures for the protection of public health against the spread of all contagious diseases, and especially of venereal diseases. The Board of Health must be aroused to a sense of its responsibility in the matter, and much can be accomplished without waiting for further legislation. As prompt cure, or at least suppression, of the contagion as soon as possible is eminently desirable, all hospitals that receive state aid should be required to have arrangements for the treatment of venereal diseases. On the other hand, all advertisements of preventives, etc., that encourage vice by promising impunity should be absolutely suppressed.

In a word, the committee concludes that the careful humane enforcement of existing laws is the best prophylaxis for venereal disease possible under present conditions. The recommendations are such as can be endorsed by physicians and ought not to arouse opposition on the part of those who have not been able to conscientiously support the methods of regulation that have sometimes been recommended.

THE PROPHYLAXIS AND TREATMENT OF RHEUMATIC ENDOCARDITIS.

Existing evidence points strongly to the fact that acute endocarditis is an infectious disorder of varying degree of severity, dependent probably upon a multiplicity of different micro-organisms. Of the diseases with which acute endocarditis is associated or that it complicates, acute rheumatism is the most common, although it must not be overlooked that the inflammation of the endocardium may be an accompaniment of any one of a number of other infectious processes, and possibly it may be the sole obvious manifestation of such a process. While there is as yet no agreement as to the bacteriology of acute rheumatism, it is generally admitted that the disease is of bacterial origin, and it is to be inferred that the primary morbid process and its secondary complications are dependent upon the same etiologic factors. Now, while we have in the salicylates an almost specific remedy in the treatment of acute rheumatism, it appears that they are inadequate to prevent the development of complicating endocarditis and likewise of exerting any curative influence upon the developed disorder. It is, therefore, a matter of no little importance to be possessed of a means capable of fulfilling these latter indications, and some observations recorded by Dr. Richard Caton[1] should prove of interest and value in this connection.

For a period of more than fifteen years, covering an experience of upward of 500 cases of acute rheumatism, Dr. Caton has pursued a plan of treatment that has yielded satisfactory results. For the rheumatism, salicylates with an occasional cholagogue are administered, and a light diet permitted. The entire body with the exception of the head is clothed in flannel and the patient is kept strictly at rest in bed for several weeks. Any lingering pains can be dissipated by the use of small local blisters.

During the period under consideration the endocardium was involved in 92 of the cases of rheumatism. In those in which it appeared probable that the endocardial inflammation had commenced and that one or more valves were acting imperfectly, the lesion being only of brief duration, absolute physical rest was enjoined for at least six weeks. Sleep was encouraged, pain and mental excitement were avoided, and the diet was simple and unstimulating. In order to stimulate the trophic and reparative process in the heart, without impairing the vitality or increasing the mechanical activity, a succession of small blisters was applied to the wall of the chest between the clavicle and the nipple. For the purpose of stimulating absorption and removal of the material effused into the substance and upon the surface of the inflamed valves, sodium iodid was administered. Of 61 of the cases in which a murmur and other signs of valvulitis existed at the time of the patient's admission, 41 left the hospital with apparently sound hearts, while in 20 the signs of valvular disease persisted. Of

1. Edinburgh Medical Journal, October, 1901, p. 335.

31 of the cases in which the bruit and other signs of valvulitis developed while the patient was under observation, 28 left the hospital with apparently sound hearts and three with valvular disease. With reference to the employment of the plan of treatment outlined it is pointed out that it is of no use unless begun early, within the first two or three weeks at least. Further, after apparent recovery has taken place the patient should for some three months refrain from arduous muscular effort and from anything that puts strain upon the heart.

GENERAL DECREASE OF BIRTH-RATE AND DEATH-RATE.

While so much is being said about the increasing sterility of American women and the decline in the birth-rate in this country, it is worth while to look around and see others as we see ourselves. Mr. William E. Curtis has recently compiled the statistics, as to this point, of a number of European countries as a piece of newspaper correspondence and the figures he gives are interesting. Taking the last twenty-five years for his study, he finds that the annual number of births per 1000 of the population has fallen from 36 to 29.3 in England and Wales, from 35.6 to 30.5 in Scotland, and in Ireland from 26 to 22.9. Other European countries have also suffered; the births per 1000 have decreased from 40.1 to 35.9 in Germany, from 30.9 to 26.2 in Sweden, from 36.4 to 32 in Holland, from 26.1 to 21.9 in France, and in less proportion in still other European countries. Only in Norway has there been an increase, and that only one-tenth of 1 per cent. It seems evident that a decrease of human fertility is one of the tendencies, or, rather, conditions of modern civilization, and that, as a rule, the higher the civilization and the more extensive the culture among the general population the greater this decrease. The exceptional state of affairs in Norway, so far as it exists, is probably correlated with a greater retention of primitive habits of living among the inhabitants; possibly also some racial factor may exist, as in Denmark, another Scandinavian country, the decrease was only eight-tenths of 1 per cent. In Sweden, on the other hand, the decrease was above the European average, so that this factor is not universally valid. In Italy the decrease was also very slight, seven-tenths of 1 per cent., but it is particularly a land where the proletariat, from climatic and other reasons, might be expected to multiply. For Russia no figures are given; its birth-rate is undoubtedly high and may not be decreasing. In the greater part of our own country we have no accurate birth records, but it is certain that we are not behind Europe as regards a declining birth-rate. It is not probable, however, that the real figures, could they be obtained, would be as formidable as some alarmists have tried to represent them, nor does a declining birth-rate necessarily indicate immoral practices as some have strongly suggested. The higher standards of living cause late marriages and a larger proportion of celibates, and while there are other legitimate causes, this alone is sufficient to reduce the birth-rate to an appreciable if not to a very considerable extent.

As regards national welfare, a declining birth-rate is not by any means a necessarily bad symptom. Taking the figures referred to again we find that parallel with the decrease in the ratio of births there has been a corresponding decrease in the death-rate. Thus in England and Wales the death-rate has fallen from 22.2 in 1874 to 18.3 in 1899; in Scotland from 23.2 to 18.6, in Germany from 26.7 to 21.5, in Holland from 22.7 to 17.1, and in other countries in varying proportions; in Hungary the decrease has been as great as 15.6 per 1000. These indicate that the increase of population need be but little affected by the lessened number of births; in England and Wales, for example, the excess of births over deaths in 1899 was still 11 per 1000, in Germany 14.6, in Holland 14.9, in Sweden 9.6, etc. Only in two countries are the statistics actually discouraging to any extent, namely, in France with an excess of births over deaths of only eight-tenths of 1 per cent., and in Ireland with its increasing death-rate of 17.6 against 17.3 in 1874 and excess of births of only 5.3 per 1000. We would almost be inclined to doubt these latter figures were it not for the fact that Ireland has been steadily drained for many years of its most productive population and the possibility that the increase of deaths may be due to its larger proportion of aged people. In France the condition may be fairly said to be alarming at the present time and its statesmen do well to seriously consider the situation.

In this country we are not so badly off. The census bulletins show a slight decrease, nine-tenths of 1 per cent., in the percentage of native whites from native parents, and a somewhat larger increase, 2.3 per cent., of those of foreign parentage, the constant disturbing influence of immigration being noticeable in all of our statistics of population. In many of the states the native-born Americans of pure-native parentage form but a small proportion of the whole, and the total of the foreign born in the population (10,460,085) in 1900 was greater than at any previous period of our history. It will be many years before population in this country reaches such an equilibrium as will enable us to fairly judge its increase from natural causes or before we have sufficiently reliable vital statistics to do so. In the meantime we may reasonably assume that on the whole we are not very much worse off than our neighbors as regards reproductiveness and that our death-rate is as low, and from indications even lower, than with the most of them. We must also bear in mind that what reliable vital statistics we have are confined to a few of the older political divisions where the disturbing elements of immigration and emigration, especially the latter, are most in evidence, and hence are not a safe index of conditions in the country as a whole.

THE EXCLUSION OF THE CHINESE.

The Chinese Exclusion Act is to be up before the coming Congress, and for sanitary reasons it is to be hoped that it will be re-enacted. In China they have settled the Malthusian problem by the use of almost every possible method of disregard of sanitation, and in this country they maintain to the fullest extent their oriental habits and traditions. As successful evaders of wholesome regulations they have hardly any equals, excelling in this respect every other foreign element in our population. This fact makes any restricted immigration of Chinese laborers under proper safeguards an impossibility; any restrictive measure must necessarily be a wholesale one. There is a great deal of wasted sentiment on this subject, and it is a hard fact that we have to meet, but we must protect ourselves. That this is a Christian country and we regard them as heathen, should not make us altruistic to our harm. The nation, like the individual, should care for and protect its own home.

THE SHIFTY ZOOPHILE.

We are still receiving communications from the antivivisectionists who, having failed in refuting Dr. Keen's charges of garbling and misrepresentation, are endeavoring to raise new issues in their attacks on the medical profession. The latest received is not signed by any individual, but instead, in typewriting, "Editor, *The Animals' Defender.*" It is strange how these people hesitate to come out openly under, or over, their own signature. In this case the animals' defender wants us to give him, or her, some notoriety by entering into a controversy about experimentation on human beings. Just what this defender of animals has to do with the defense of human beings against savages known as physicians we do not know. THE JOURNAL has treated these antivivisectionists with all due courtesy in the past, but declines to open new subjects till their controversial morals have improved and they acknowledge what all the world can see, that their misrepresentations and garbling of quotations have been amply demonstrated by Dr. Keen. It is a pity that would-be reformers have so often such unsymmetrically developed consciences, and that the good cause of humanity to all living beings, not excluding mankind, should be injured by cranky extremists and utterly unscrupulous advocates.

ON THE DEFINITION OF INSANE DELUSION.

The definition of an insane delusion is one of the stumbling blocks of medical experts, second only to that of insanity, a definition of which in a complete and satisfactory way is an impossibility. The fact that false beliefs are held by a large proportion of mankind, and that some of the most utterly irrational are persistently maintained, by apparently intelligent persons in other respects, confuses jurists and the public, and is sometimes used to obscure actual evidence of mental disorder. It is important that physicians, at least, should have clear ideas on this subject and be able to give a reason for the faith that is in them when called to testify as to the value of such indications. In a recent paper[1] C. H. Hughes discusses this subject and offers what in his opinion is the correct criterion of an insane delusion. Taking as his text a recent contested will case in which the sanity of a deceased believer in eddyism was challenged, he points out that only false beliefs due to an existing condition of brain disease can properly be called insane delusions. It is not the mere perversion of the intellect, but the morbid element that is evidence of insanity. "Insane delusions," he says, "are subjective errors of judgment of entirely false judgments brought about by a mind involved in disease implicating the brain. The insane mind may momentarily assent to the unreality of a delusion, but immediately reasserts it." This is probably as satisfactory a definition of an insane delusion as can be given; it covers the conception, but, with every other definition of the kind, it does not always materially aid in the diagnosis. It is perfectly possible to suppose, for example, a person at a spiritualistic seance accepting and interpreting the phenomena according to his mental morbidity, while the others about him are merely exercising the credulity of the average believer. The differentiation of the psychopathic from the non-psychopathic beliefs is, therefore, still sometimes a problem for the expert, and, as Dr. Hughes points out, all the other stigmata, physical as well as mental, must be studied. Delusions are, therefore, not in themselves the first or exclusive criteria of insanity; they are evidence only in connection with other symptoms of a diseased brain by which their pathologic character can be determined.

1. Alienist and Neurologist, October.

THE TETANUS CASES IN CAMDEN, N. J.

The Board of Health of Camden, N. J., where a recent epidemic of tetanus after vaccination has occurred, has sent out a circular giving the facts of the case. Samples of all the different makes of vaccine employed have been tested by the State bacteriologist of New Jersey and found free from tetanus germs, which fact alone shows that the vaccine matter itself was innocent in these cases. The history of each case of tetanus, moreover, has been carefully collected. In every case vaccination was practiced in a cleanly and correct manner, the subsequent infection being due to the patients' own neglect or that of their parents, and their omission to present themselves to the attending physicians to receive proper attention. One case of tetanus occurred in a boy who had not been vaccinated, but had received a gunshot wound, thus showing that the infection is not confined to any particular source. A still further evidence of the innocuousness of vaccine matter itself is noted by the fact that in no case did it appear until long after the usual incubation period, as in every case the tetanus occurred not less than three or four weeks after vaccination. It developed also with every make of vaccine employed. Animal experiments also demonstrated the freedom of the vaccine from tetanus germs; in no case was tetanus produced on a susceptible animal. Moreover, during the past three weeks a very large number of persons were vaccinated in Philadelphia and elsewhere with vaccine from the same sources as that used in Camden, and no tetanus followed. The only reason for the epidemic that can be assumed is the atmospheric and telluric con-

ditions that have existed. There had been a long period of dry weather, with high winds, so that tetanus germs have been constantly present in the atmosphere. It is noticed that in all cases after a careful examination that the patient was exposed by the scab being knocked off or removed, infection resulting, and frequently by the children picking the scab with their dirty fingers. Facts then would seem to exonerate the vaccine from the accusation of having produced tetanus in these cases. It may be possible that a vaccination wound offers a specially favorable nidus for tetanus germs, more so in fact than an ordinary cut or open wound. The number of cases following vaccination would make this seem possible, if not probable—hence the need of more care for complete asepsis and the prevention of any possible contact with infected matter in such cases. It is unfortunate, however, that there has been any such coincidence of tetanus and vaccination, since the occurrence of these cases will be used to the utmost by anti-vaccinationists without regard to the actual facts in the case.

INDIGESTION AND SIN.

A prominent surgeon who holds certain eccentric opinions in regard to dietetics is reported to have said that "total depravity is often nothing more than total indigestion." There is less wisdom in this statement than some might think; it is one of those utterances that catch the vulgar and is consoling to those who have good digestions, but who do not feel otherwise safe as to their salvation. Dyspepsia may make a man unpleasant in some ways; it is apt to aggravate any existing sourness of disposition, but in its more pronounced forms it has, at least, a tendency that leads its victims to appreciate the vanity of earthly things. The Frenchman's recipe for happiness—"a good stomach and a bad heart"—agrees better on the whole with the natural depravity of mankind, as we see it in daily life. If we sum up and average human villainy, we will probably find that the dyspeptics have not been the greatest criminals, and if we were to poll the sufferers from gastric symptoms we would not find among them any undue proportion of depravity. In fact, it is the cheerful happy-go-lucky individual that creates the most trouble; he is the one who yields to all the pleasant vices; he does not pay his debts, but lets the other fellow walk and worry and he cultivates egoism generally. The smooth, calculating villain is also a non-dyspeptic, and if we take the mass of pleasant, benevolent-looking visages we would probably find that they do not necessarily attend any special corresponding virtues, but often simply mean that the wearer has been good to himself. They may also mean a sort of dementia; this is perhaps as often as not the signification of the look of peace and content so coveted by female eddyites and such. The strenuous life that we talk of and that most of us are obliged to live, is not specially conducive to placid looks, and still less so with the more or less abdomino-visceral disturbance that is often its accompaniment. The opinion quoted as co-relating total depravity and indigestion may be taken as a sample of statements that are more epigrammatic than sensible.

Medical News.

COLORADO.

Health Department Needs.—The Denver Health Department has asked for a $60,000 appropriation for 1902.

Found Not Guilty.—An irregular physician of Ouray, tried on the charge of practicing medicine last April, without a license, was found not guilty in Judge Stevens' court, November 15. The case will probably be taken to the Supreme court.

Trainmen Instructed in First Aid.—One of the resident surgeons of the Union Pacific Railway in Denver has commenced a course of instruction for trainmen on first-aid. The first lecture included shock, the application of temporary dressings, and temporary hemostasis.

Physicians Must Register.—Dr. Seymour D. Van Meter, secretary of the State Board of Medical Examiners, has issued an ultimatum to the physicians who have not complied with the state law which makes necessary the recording of their certificates with the county clerk. He will have the licenses revoked of those who fail to obey the order in a reasonable time.

Outdoor Sanitarium.—The Rocky Mountain Industrial Sanitarium, organized in Denver last spring, is now in operation. On a ten-acre tract, five miles from Denver, fifteen or twenty patients in the early stage of consumption are, under the plans of the promoters, virtually taking care of themselves. The rules of the institution compel a continuous outdoor life to be maintained summer and winter. Each patient is provided with a roomy tent, plenty of warm clothing and blankets, and a small stove to be used only in extremely cold weather. Experience has proved that with proper food and clothing, and a life in the open air and sunshine, artificial heat is unnecessary, and becomes absolutely unbearable to the patients, who without exception are gaining rapidly. The co-operative idea has already been put into force, for many of the patients are supporting themselves wholly or in part by doing the work on the premises.

ILLINOIS.

Addition to Peoria Hospital.—The addition to the Cottage Hospital, Peoria, erected by John C. Proctor at a cost of more than $140,000, is now complete and will be formally dedicated and opened in a few days.

Rock Island County Medical Society has been incorporated at Rock Island by Drs. Carl Bernhardi and George G. Craig, Rock Island, and Dr. Lewis D. Dunn, Moline, not for profit, but for medical and scientific research.

Smallpox is increasing throughout the state, but especially in the central and southern portions, despite the efforts of the State Board of Health. Springfield has 4 cases; at North Alton the public schools have been closed on account of 9 or 10 cases; Carlyle reports one case; Clayton has two cases and the public school has been ordered to be closed.

Personal.—Dr. Robert E. Calhoun, Chesterville, has moved to Arcola.——Dr. James H. Pittman, Roseville, has opened an office in Camp Point.——Dr. William D. Nelson, Jr., Marietta, is about to locate in Canton.——Dr. George H. Fricke, Park Ridge, who has practiced in that village for thirty years, has sold his practice to Drs. Charles A. Dodson and Charles M. Noble, and has moved to Chicago.——Dr. Charles P. Spann has disposed of his interests in Thebes and will move to Alto Pass or Murphysboro.

Chicago.

Mercy Hospital has purchased for $20,000 property on Prairie Avenue and expects to extend the hospital to cover the 98 feet of frontage thus secured.

The Hospital of the Sisters of the Holy Family of Nazareth has negotiated a loan of $150,000 to complete their new hospital building just erected at a cost of $400,000.

People's Hospital and Training School, to conduct a hospital and training school for nurses, has been incorporated at Chicago by Drs. I. C. Gary, Gordon G. Burdick and George W. Webster.

Charity Hospital Not Liable.—Judge Chytraus, in a suit for $25,000 damages brought against the Presbyterian Hospital on account of injury alleged to have been the result of a mistake in medicine made by a nurse, instructed the jury to find for the defendant on the ground that a hospital chartered for the purpose of receiving and treating patients without charge is not liable for the carelessness or negligence of its servants, providing it has selected those servants with due care.

IOWA.

Dr. J. W. Crofford, Lamoni, has been taken to Fort Madison to serve out his sentence of thirteen years' imprisonment for criminal abortion and murder in the second degree.

Dubuque detention hospital for contagious diseases is to be erected immediately at a cost of $1500. The plans provide for a one-story frame building 60 by 24 feet, with two wards and four private rooms.

Smallpox Bill Paid.—Dr. Charles H. DeWitt, Glenwood, who rendered an account of $1150 for caring for smallpox cases in Mills County last winter, but was obliged to sue the board of supervisors, as they reduced the bill to $900, has settled the case out of court, and will receive the full amount of his claim.

The Insubordination of Dr. Pray.—The State Board of Medical Examiners has referred the case of Dr. Gilbert L. Pray, Lake City, to the State Board of Health for action. Suit had been brought against him to revoke his certificate, but it was shown he was competent and recognized the smallpox cases in Lake City, but failed to report them. The case is, therefore, one for the action of the health board by criminal prosecution. He has repeatedly refused to report smallpox cases.

Smallpox.—Dr. E. W. Burke, Iowa Falls, informs us that there are seven well-developed cases of smallpox in that city. ——Laporte is quarantined on account of the diseases; churches and schools are closed and public meetings prohibited.——At the Musquakie Indian Reservation, Tama County, there have been 35 deaths out of 65 cases.——Sioux City has now about 50 cases of the disease.—It is reported that there are about 30 cases in Waterloo.——Six cases are reported from Flint River township, Des Moines County, two from Marion County, one from Charles City and four from Reed township, Clayton County.——At Ida Grove there are 28 cases.——In Denison 13 cases have been discovered.

KENTUCKY.

Dr. De Vault Guerrant, Richmond, has located in Stoops, Madison County.

Smallpox is increasing in Bath County.——At Roe's Run a case has been reported.——Several cases have been discovered at Red Lick, Madison County.——At Jackson, Breathitt County, there are from 60 to 75 cases owing to violent opposition to vaccination.——Two cases have developed in Lexington.

The Doctor Wins.—The judgment of the Henderson Circuit court in the case of Dr. W. W. Walker against the city of Henderson was reversed by the Appellate court, with instructions to enter a judgment for appellant for the fair value of services rendered. Dr. Walker was placed in charge of the county pesthouse during the smallpox epidemic of 1899. He sued to recover on a contract for services at the rate of $15 per day.

Dr. and Mrs. Henry Martyn Skillman, Lexington, celebrated the fiftieth anniversary of their marriage, October 30. Dr. Skillman has practiced in Lexington for fifty-four years, was probably the first physician who administered chloroform in the West, and is the only living member of the faculty of the medical department of the old Transylvania University. He was president of the Kentucky Medical Association in 1869, and has been a member of the American Medical Association for more than forty years.

MARYLAND.

The Medical and Chirurgical Faculty of Maryland now has 680 active and 17 honorary members.

Students Enrolled.—Of the 656 students enrolled at the Johns Hopkins University 227 are candidates for the degree of M.D. and 25 are physicians in attendance.

Baltimore Mortality.—For the week ending November 23 there were 200 deaths, 21 being from pneumonia, 17 from consumption, 8 from cholera infantum, 3 from typhoid fever and 2 from diphtheria.

Personal.—Dr. G. Herbert Beckley has located at Reisterstown, Baltimore County.——Dr. C. H. Ohr, the oldest past grandmaster of masons in the world, is ill at his home in Cumberland.——Dr. Jackson Piper, Baltimore, sailed for Europe November 23, and will be gone all winter.——Dr. Remsen, President of Johns Hopkins University, was given a reception at Bryn Mawr College, Pennsylvania, November 22.

The Instructive Visiting Nurse Association of Baltimore, designed to provide trained nurses to visit in their homes the sick poor who can not or should not be sent to a hospital, and to instruct their families and friends in simple, necessary rules for the care of the sick, reports 9766 visits during the year for nursing, 2192 visits for advice and instruction, and 1236 new visits. From June to September, inclusive, 3112 visits were made. Mrs. William Osler is secretary of the association.

State Board of Health Report.—The annual report of the State Board of Health contains the reports of the secretary, Dr. Fulton, of the chemist and bacteriologist, of local health officers, etc. Dr. William H. Welch, President of the Board, calls attention to the fact that in it, for the first time in the history of the state, is presented an approximate account of a year's losses through death and an accurate exhibit of the relative importance of preventable causes of death. He calls attention particularly to "the overshadowing importance of tuberculosis," and suggests that Maryland single it out "for direct attack." He calls attention to the inadequateness of the inspection of animals and meat at the abattoirs. That the epidemic of smallpox which has been steadily increasing in the United States since 1898 has inflicted no great injury on Maryland, is due, he thinks, to the high estimate by the people of vaccination and the vigilance of the local authorities, especially those adjacent to infected areas in neighboring states. The present burial permit law went into effect in June, 1900. Dr. Fulton points out that tuberculosis heads the list of mortality with 12.7 per cent., pneumonia having 5.9, infantile diarrhea 10.2, and typhoid fever 4.5 per cent. The ratio of deaths from preventable diseases to total mortality is 39.4 per cent. The book contains the reports of 35 out of 43 organized local boards of health. The chemist reports 173 examinations of water. The bacteriologist reports 1137 examinations for typhoid, tuberculosis, diphtheria and malaria.

MICHIGAN.

Passive Criminals.—Dr. Fred R. Belknap, Niles, thus characterizes physicians who fail to report suspected cases of dangerous communicable diseases.

War on Quacks.—The Wayne County Medical Society has appointed a committee to co-operate with the prosecuting attorney in prosecuting all physicians who practice without legal graduation and registration.

Battle Creek Sanatorium Exempt from Taxation.—The Circuit court has decided that the Battle Creek Sanatorium is a charitable institution and as such is exempt from taxation. The institution sued the city for $5245.35 taxes paid under protest and has received a verdict, with interest. The case will probably be carried to the Supreme court.

Smallpox is said to exist at 87 places in the state, and 1500 cases of the disease are known to exist.——In the logging camps of Kalkaska County, it is prevalent, and a pesthouse is being built.——A death has occurred at Yuma.——Floodwood is strictly under quarantine.——Houghton County has more than 30 cases.——Cases are reported in the Upper Peninsula, from Metropolitan, Niagara, Escanaba, Bay de Noc and Indian town.——Dr. Albert B. Simonson, of the Calumet and Hecla Mining Company, has the disease and is quarantined at his home in Calumet.

NEW YORK.

Smallpox has appeared in Olean and Corning.

Emergency Hospital for Utica.—The Ravine Hospital, Utica, is being put in shape to care for contagious diseases.

State Hospital Site.—The board of trustees of the State Hospital for the Care of Consumptives, after inspecting many sites, believe that Raybrook, on the west side of the Adirondacks, is the best suited for the proposed institution. While Gov. Odell has not finally approved of this site it was learned that he thought it the most available of those inspected.

Buffalo.

Free vaccination dispensaries have been inaugurated by the Health Department, one in the heart of the Polish district, the other in the Italian tenement house district.

The Retention of Wende.—Mayor-elect Knight gave a hearing to those desiring the retention of Dr. Ernest Wende as Health Commissioner. A petition of over 300 prominent physicians, together with a business-men's and bankers' petition, was presented. Dr. Wende, however, we hear has not been retained.

For Examining Bullets.—Herbert M. Hill, city chemist and professor of chemistry at the University of Buffalo, and Dr. Herman G. Matzinger, of the New York State Cancer Laboratory, have each been awarded $150 for examining chemically and bacteriologically the bullets used by the assassin of the late president.

Marine Hospital Needed.—The International Seamen's Union, which was in session in Buffalo, has passed resolutions petitioning the surgeon-general of the Marine-Hospital Service and Congress to increase by better hospital facilities the service in Buffalo. At present there is no district marine hospital in Buffalo, but a ward is leased for the care of seamen in one of the hospitals.

Smallpox Situation.—Nine new cases of smallpox were reported November 27 at Buffalo. A free dispensary for vaccination was opened in the Polish district, but this not sufficing the police have been instructed to assist in compulsory vaccination. Buffalo finds herself with an isolation hospital inadequately heated and improperly equipped. Only a few patients can be accommodated, and should the number of cases increase the city will find itself in a bad plight.

New York City.

Dr. Charles Walsh, Brooklyn, while walking in Fifth Avenue, slipped on the ice, and falling sustained a fracture of the right patella. He was taken to the New York Hospital.

Appointments.—The Commissioner of Corrections, Brooklyn, has appointed a physician at the Kings' County Penitentiary at a salary of $900 a year. The Board of Health has appointed eleven additional medical inspectors of schools.

X-Ray Laboratory Donated.—The late Edward N. Gibbs, of Norwich, Conn., left by his will, instructions to equip a laboratory for experiment and use of *x*-ray apparatus for Bellevue Hospital Medical College. This is now completed and is known as the "Edward N. Gibbs *X*-Ray Laboratory of the University and Bellevue Hospital Medical College."

Longevity.—Dr. A. L. Wood read before the last monthly meeting of the Hundred Year Club a paper on "The Influence of Water Upon Health and Longevity." He said that for the last twenty years he had used distilled water freely, and in the past year had drank about a gallon a day. His own robust appearance, together with certain physical feats that he performed, were offered in proof of his views regarding the benefits to be derived from taking water in this way.

NORTH DAKOTA.

New Licentiates.—The State Medical Board announces that ten of the recent applicants for licenses were successful.

Smallpox.—The city school at Mayville has been closed on account of a case of smallpox.——Grand Forks has a case of confluent smallpox.——Fargo has had a fright, because a blind pencil-vendor's boy, after going about town all day, was found to be ill with smallpox.

Personal.—Dr. Olaf Th. Sherping, Enderlin, will locate in Fergus Falls, Minn.——Dr. James Halliday, Reynolds, has decided to locate in Osnabrock.——Dr. William L. Grant, St. Thomas, has moved to Grand Forks.——Dr. William B. Coyle, Lakota, has taken into partnership Dr. James W. Wells, St. Paul, Minn.——Dr. William D. Wagar, Crary, has located in Michigan City.——Dr. William C. Langhorst, Steele, has moved to Chicago.

OHIO.

Children's Hospital on Fire.—Nine sick children narrowly escaped being burned to death in a fire which damaged the Children's Hospital, Cleveland, November 20.

Dr. David H. Miller, Newark, has been prosecuted by the city health officer for failing to report a case of smallpox, the patient being his wife. The home of Dr. Miller has been quarantined.

The "Doctor" Disappeared Under Fire.—Dr. Giuseppe A. Purpura, Cleveland, the Italian whom the State Board of Medical Examiners suspected of practicing under a false diploma and whose case was still under consideration, suddenly left Cleveland and numerous unconsoled debtors.

PENNSYLVANIA.

The Shamokin Board of Health has elected the following officers for the ensuing year: Dr. J. W. Bealor, president; C. F. Heim, secretary; Dr. Richard H. Simmons, medical inspector, and Francis Hoover, health officer.

The Rights of Consumptives.—The right of consumptive immigrants to land in this country has been denied by the United States Circuit Court in Brooklyn, N. Y., in the case of Thomas Boden, an alleged or supposed consumptive of Philadelphia, who is held at Ellis Island, and will be deported unless the decision of the court is overruled.

Personal.—Dr. Samuel C. Brietenbach, the oldest physician in Roxborough, is seriously ill with pneumonia.——Dr. Isaiah J. Wireback, Monessen, has located in Uniontown.——Dr. David H. Warner, Lebanon, has been appointed municipal physician.——Dr. Charles W. Jennings, Danville, has been appointed one of the resident staff at the Harrisburg Hospital, to succeed Dr. John Howard.

Scarlet Fever.—Shamokin had 88 new cases of scarlet fever reported in November.——In York City, 14 cases are reported by one physician.——The disease is epidemic in Freeport, where 34 cases exist.——In Mifflin township, the villages of Whittaker, Homeville and Bellwood are alarmed because of the prevalence of the disease.——A serious epidemic has broken out at Munhall near Pittsburg, where 20 cases have been reported in the last few days.——The schools in East Fallowfield township have been closed on account of the disease.——There are so many cases at Canonsburg that the public schools have been closed.——The schools at Natrona have been closed on this account.

SOUTH DAKOTA.

Personal.—Dr. Robert L. Murdy, Aberdeen, has been appointed surgeon for the Milwaukee road, vice Dr. Samuel J. Coyne, deceased.——Dr. George MacMurphey, Elkton, will locate in Ortonville, Minn.

Canton Hospital Accepted.—The Asylum for Insane Indians at Canton, erected for the government at a cost of $53,500, and intended to accommodate all the insane Indian wards of the government, is completed and has been accepted.

Compulsory Vaccination in Yankton.—The Yankton County Board of Health has ordered that after Jan. 1, 1902, no child or student be admitted to any school or college within the county without a physician's certificate of successful vaccination.

Smallpox is making its appearance in the Black Hills.——Nine cases are reported from the vicinity of Gayville and the same number from Garrettson.——The public schools at Hot Springs have been closed on account of a case in the family of a janitor.——Gayville has been quarantined on account of the disease.

TENNESSEE.

Personal.—Dr. Plummer Haynes, Nashville, has located in Lynnville.——Dr. James K. P. Blackburn, Lynneville, has moved to Oklahoma City.

Smallpox is prevalent at Liberty, where several cases have developed and the public school has been closed; at Dresden, where three cases are reported; at Savannah, where there are six cases, and at Pittsburg Landing.

Anti-Cocain Crusade.—The Chattanooga authorities are making energetic efforts to put a stop to the illegal dispensing of cocain by druggists. The first-fruits appeared when, in the first case, the druggist was fined $25 for the offense.

Knoxville City Hospital.—The following became members of the staff of the new city hospital: Consulting—Drs. John M. Boyd, Michael Campbell, Chalmers Deaderick and John M. Kennedy; medicine—Drs. Benjamin D. Bosworth, William R. Cochrane, William Delpuech, Charles P. McNabb and David H. Williams; surgery—Drs. Benjamin B. Cates, Thomas Ap. R. Jones, Henry J. Kelso, Samuel R. Miller and Walter S. Nash; gynecology—Drs. James M. Black, James S. Garrard, Samuel M. Miller and Robert P. Oppenheimer; eye, ear, nose and throat—Drs. Claudius M. Capps, Charles H. Davis, John H. Kincard, and Benjamin F. Young; diseases of children—Dr. Ernest R. Zemp; dermatology—Drs. W. S. Austin and James F. Scott, Jr.; obstetrics—Dr. Samuel L. Jones; pathology—Dr. W. R. Lockett.

TEXAS.

Anti-Expectoration in Austin.—An ordinance has been introduced in the city council making expectoration on the sidewalk an offense punishable by a fine.

Medical Examiners' Meeting.—The next meeting of the Board of Medical Examiners for the State of Texas will be held at Waco, beginning on Tuesday, May 13, 1902.

Personal.—Dr. Herbert E. Stevenson, El Paso, has been appointed state quarantine officer at that point, vice Dr. Charles F. Norton, transferred.——Dr. Bruce Wallace, Houston, was thrown from his buggy, November 22, and seriously hurt.

The Boyd-Brumby controversy in Houston has been ended by the city council, which at its meeting, November 25, created the office of chief medical inspector and appointed Dr. Brumby thereto. Dr. Boyd still holds office as Health Officer.

Plague Quarantine Raised.—On November 18, following advices of Surgeon-General Wyman, United States Marine-Hos-

pital Service, State Health Officer Tabor raised the quarantine against Glasgow and Liverpool.

WASHINGTON.

Contagious Diseases.—Two cases of smallpox have developed at Farmington.——Colton has formed a board of health, which promises strict quarantine of all cases of smallpox in the town until the disease is stamped out.——The Dalles has an epidemic of diphtheria.

Personal.—Dr. Irwin A. Stiles, of the Northern Pacific steamship *Olympia*, has given up the sea and will locate in Tacoma or Seattle.——Dr. Dunlop Moore, U. S. Marine-Hospital Service, who has just returned from Alaska, has been ordered to the Philippine Islands.

Northern Pacific Training Nurses.—Chief Surgeon Courtney, of the Northern Pacific railway, has made a new departure by opening a training school for nurses in connection with the railway hospitals. Preference is given to daughters or female members of families of employes. The headquarters will be at Brainerd, Minn.

"Not Guilty, But Don't Do It Again."—A "doctor" of Spokane charged with practicing medicine without a license as required by the law of 1901, was found not guilty, the law was declared constitutional, and the defendant was warned that, should he practice without first having taken the required examination and procured a license, he would be prosecuted.

CANADA.

Surgeon-Captain Keenan has been presented with the Cross of the Distinguished Service Order, a decoration only eclipsed in value in so far as military decorations are concerned, by the Order of the Indian Empire. Dr. Keenan was the surgeon to the Strathcona Horse in South Africa.

Ottawa's Death Rate.—The total number of deaths in Ottawa for the past civic year, as shown by the Medical Health Officer's report, was 1273. The report shows a slight increase over last year, which totaled 1146. The largest number of deaths among adults was caused from tuberculosis, 125 in all. Next came pneumonia with 102; heart disease, 88; convulsions, 72; old age, 73; diphtheria, 65; scarlet fever, 52.

Toronto Orthopedic Hospital.—In the Third Annual Report of this hospital is shown that during the three years of its existence the receipts have arisen from $2,601.52 to $6,444.83 in the second year and $12,343.23 in the third year. So great have been the demands upon this hospital that a new site has been secured and improvements are now under way which will cost $30,000. When completed the new building will accommodate 60 patients.

A Dowieite Sentenced.—Eugene Brooks, an elder of Dowie's Christian Catholic Church in Zion, was, on November 27, found guilty and sentenced to three months' imprisonment without hard labor for aiding and abetting a man who was recently found guilty of manslaughter at Victoria, B. C., who had failed to provide his infant children suffering from diphtheria with proper medical attendance. The Appellate Court of British Columbia has determined that medical attention is a necessity of life.

Smallpox.—St. Michael's Hospital, Toronto, is under strict quarantine owing to a case of smallpox having inadvertently gained access to its wards.——Toronto has just opened a new smallpox hospital. It cost $5,000 and has accommodation for 25 patients.——In the Province of Quebec there are 81 places where smallpox has broken out, and in all there have been 340 cases. There are at present 32 cases in the Civic Hospital in Montreal. Four inspectors have been appointed in Montreal to watch all trains as they come into the city. In Quebec City 88 houses have been placarded since the beginning of the outbreak, and there are at present 23 placarded and quarantined.

Toronto Sick Children's Hospital.—The 26th annual report of this institution shows that since the foundation of the hospital 43,204 children have been treated and that 20,000 have been restored to full health. During the past year 770 were cared for in the indoor departments and 5500 in the outdoor departments. Of the indoor patients 530 were cured, an increase of 147 over 1900, while 154 were improved and 44 unimproved and 42 died, a decrease of six as compared with the previous year. Seven of these died within three hours of their admission, eight within six days, five within two weeks and twelve within the month. There is at present a deficit of $13,000 on this hospital.

A Toronto Judge on Hospital Fees.—One of the leading surgeons of Toronto recently sought to recover from a hospital patient the moderate fee of $30 for an operation for appendicitis. The judge decided in favor of the patient, thus delivering himself on the question of charging hospital patients any fee: "The public has a right to assume that the treatment is free. These institutions are supported by charity, donations, grants, etc., and therefore the presumption is, at least so far as the public wards are concerned, that all treatment is to be free. The right to pay depending upon the ability to pay is not recognized in law. If patients have to pay then it is not a public institution. Doctors on the staff can not recover unless they first notify the patient of the rules and regulations of the hospital."

FOREIGN.

Sir William MacCormac Dead.—A cablegram announces the death of this celebrated English surgeon, December 4. A full report will be given in next issue.

Plague in Russia.—Advices from Vienna state that the bubonic plague is alarmingly prevalent in many cities in Southern Russia.

Scientific Prizes at Budapest.—The Budapest Medical Society has conferred its endowed prizes this year on Hoegyes, Lenhossek and Schaffer for their work on internal medicine, anatomy and neurology. The prizes average 800 kronen.

Smallpox in London.—On November 30, there were 420 cases under treatment. Up to that date 116 persons had died of the disease and 233 had recovered. The exceedingly high mortality is due to the fact that London is the "worst unvaccinated city in the civilized world."

Vienna Medical Club.—This club was organized for social purposes exclusively, but it has now been transformed into a scientific society, the "Gesellschaft fuer innere Medizin," with three presiding officers of the three medical clinics of the university, Nothnagel, Neusser and von Schroetter.

Honors to Baccelli.—A committee has been formed at Rome to present Baccelli with a gold medal in token of appreciation of the great success of his endovenous injections of sublimate in arresting and curing foot and mouth disease in the southern countries of Europe. The government pays the expense of this treatment of cattle in Italy.

Semi-centennial of the Ophthalmoscope.—Helmholtz presented his ophthalmoscope to the Koenigsberg Medical Society Nov. 13, 1851. The semi-centennial anniversary was celebrated at Berlin by a collection of historical exhibit of ophthalmoscopes in the ophthalmic clinic at the Charité, besides numerous meetings, etc., devoted to the subject. About 120 specimens were collected from various countries.

Statues to Pasteur.—The little mountain town of Arbois was the home of Pasteur's youth and he always sought it on his vacations. The town recently unveiled a fine statue of its illustrious son. Paris is also erecting a statue to Pasteur to be surrounded by six groups, each sculptured out of a single block of marble, the pediment to consist of twenty-five such blocks. It was originally designed for the Medicis Place, but the proximity of the underground railway suggests the possibility that the foundations may not be strong enough for such a weight, and the statue will probably be erected in the Place de la Sorbonne. It is proposed to print Pasteur's life in pamphlet form and distribute it among the children of France as the most imperishable monument that could be offered him.

Deaths in the Profession Abroad.—The entire number of the last *Brazil-Medico* is devoted to eulogies of Professor F. de Castro of Buenos Ayres, who died November 11. The funeral procession included more than two thousand mourners, from the President of the republic of Brazil to weeping charity patients. De Castro's principal works were on heart disease, propædeutic medicine and sanitary subjects. His native city, Bahai, has ordered a memorial tablet to be placed on the house where he was born in 1857, and named the street from him.——The death of Professor S. E. Sosa is announced from Mexico, and also of Dr. F. Semeleder, who accompanied Maximilian to Mexico as his body physician, and settled there after

the emperor's death.——The professor of laryngology, Dr. E. de Rossi, recently died at Rome.

Nobel Prize for the Founder of the Red Cross.—The committee appointed by the Legislature of Sweden and Norway to confer the Nobel prize of $50,000 to be awarded to the person who has done the most to promote peace, passed over the apostles of arbitration and the writers and artists who have portrayed the horrors of war. The choice, we are told, wavered between Frederick Passu, the aged pioneer of the idea of universal peace, and Henri Dunant, the founder of the Red Cross, finally deciding upon the latter. Dunant was born at Geneva, Switzerland. He served as a volunteer assistant in the field hospitals during Napoleon's campaign in Italy, in 1859. Amidst the desolate scenes of the battle of Solferino he conceived the idea of an international organization to relieve the sufferings on the battle-field. He published a book, "Memories of Solferino," which was translated into many languages and prepared the soil for the germination of the idea of the Red Cross Society. He devoted all his energies and means to the realization of this ideal, and is now living in poverty in his old age. The prize endowed by the City of Moscow, to be awarded at the international medical congresses, was also bestowed on Dunant.

Correspondence.

The Enforcement of Medical Laws.

LAWRENCEBURG, KY., Nov. 23, 1901.

To the Editor:—The editorial and original articles in the issue of THE JOURNAL of November 16, discussing the enforcement of medical laws, are worthy the attention and approbation of every member of the profession in America. As a Kentuckian, I appreciate the tribute you pay to the profession of Kentucky in its effective work in ridding the state of quacks. Individually, however, on account of my recent experience in dealing with a quack, I am not so enthusiastic and feel that my efforts in protecting the profession and the public will hardly be so "strenuous" in the future as they have been in the past. Your suggestion that "what is needed to enforce the medical laws is a well-organized state society with its branches ramifying into every county and with a paid attorney of its own, to act for the profession, independent of, or as an assistant to, the public prosecutors" is good as far as it goes, but I would go one step further and suggest that the state society create a fund by collecting a small annual assessment fee of its members not only for the purpose of paying its attorney but to meet the expenses of adverse judgments, damages, costs, etc., that may accrue from litigation.

As indicated by THE JOURNAL, and by Drs. Happel and Harison, the co-operation of the county and state societies is absolutely essential for the enforcement of medical laws. Individual effort counts for naught, besides incurring great annoyance, public opprobrium, loss of time and most probably the expense of defending a civil suit for damages by the quack who is instigated by some envious member of our profession, as the following personal experience forcibly illustrates:

In April, 1899, while passing the street, my attention was attracted by the "spiel" of a quack announcing the virtues of his remedies, consisting of an "electric belt," which he offered for sale, and bottles of a nostrum which he gave to each purchaser of a belt. This mere announcement you will note by referring to the laws regulating the practice of medicine in Kentucky clearly brought the quack within the jurisdiction of the medical practice act. It occurred to me to consult the prosecuting attorney and to learn if there was a legal way to dispose of this faker. After consulting the statutes he informed me that there was a way of instituting legal process, but refused to act unless I assumed all responsibility of the warrant causing his arrest; this I did. The quack was arrested and finally brought to trial; however, he was not incarcerated in the meantime but released on his own recognizance. A hung jury resulted from the first trial, and he was released on the second trial. However, his easy escape is easily accounted for by a most remarkable condition of affairs. Out of six local physicians three testified in favor of the quack, claiming, in their opinion, that he was not engaged in the practice of medicine within the meaning of the medical practice act. What is more remarkable still, one of the three physicians who testified favorably to the quack instigated him to bring a civil suit for damages against me for $5,000 and admitted under oath on the witness stand that he had been in communication with the quack relative to employing counsel for him. The mere fact that a physician had caused the arrest of the quack, especially when the latter was supported by one-half of the local physicans, was sufficient to prejudice the jury. The jury's verdict against me was $500 and costs and the trial judge, notwithstanding he admitted the verdict was a gross outrage, refused to set it aside. I appealed the case, but it was affirmed with damages. The judgment, damages, costs and attorney fees stand me out something more than $800. However, the State Society at its last meeting appointed a committee to aid me in the case, which collected by private subscription from the members $115. While this was duly appreciated I would have preferred it had come from the Society as a body. The State Society refused to appropriate any of its funds to aid the case. The State Board of Health could not afford aid, as it was in debt and it did not have sufficient appropriation from our liberal legislature to properly conduct its own affairs. Aside from the above assistance mentioned I have fought this quack alone and suffered the humiliation of having three out of six local physicians go on the witness stand against me. Henceforth, I propose to give quacks a wide berth, unless I can secure the co-operation of the county and state societies.

GEORGE E. DAVIS, M.D.

Bismuth Poisoning.

PHILADELPHIA, Nov. 26, 1901.

To the Editor:—I was greatly interested in the Editorial entitled "Intoxication with Bismuth," published in the issue of THE JOURNAL for November 23. I have long been aware of the fact that bismuth applied to sore surfaces may exert a toxic and even a fatal effect. Several years ago there was a patient in the Woman's Hospital here with an extensive burn of one arm, over which bismuth subnitrate had been thickly dusted. The powder had united with the secretions of the ulcerated surface and formed a thick "cast" like that of plaster of Paris. The patient developed acute stomatitis characterized by great pain, tenderness and swelling, and broad bluish lines along the edges of the teeth and the inner borders of the lips. I have no record of the case, and can only state that the patient fell into a state of profound asthenia and died from what I regarded as bismuth poisoning. The United States Dispensatory (18th Ed., p. 275) states that the insoluble preparations of bismuth "when applied in large quantities to extensive wounded surfaces are capable of yielding so much bismuth by absorption as to produce a poisoning which is characterized by acute stomatitis, with a peculiar black discoloration of the mucous membrane, usually beginning upon the borders of the teeth, but spreading over the whole mouth, followed by an intestinal catarrh, with pain and diarrhea; in severe cases, desquamative nephritis, as shown by albuminous urine and epithelial tube casts, may also occur." Although the authority for this statement is not explicitly stated, it is evidently taken from Kocher, who wrote upon the subject in 1882, and who is quoted in the paper on bismuth poisoning by Dreesmann, upon which the editorial above referred to was based. Yours truly,

FREDERICK P. HENRY, M.D.

Prescription Writing.

VERMILLION, S. D., Nov. 25, 1901.

To the Editor:—The subject of "Prescription Writing," taken up by THE JOURNAL, is undoubtedly a timely one and I would suggest that the series of articles be reprinted and published in pamphlet form so they may be more convenient for reference.

For my part, I was fortunate enough to have some knowledge of Latin before studying medicine, but I find that things will easily slip the memory and I would take great pleasure in getting these timely articles in such a form that they could have a place on my desk.

No one who has ever looked over the prescriptions filed in the drugstores will doubt the necessity of a more thorough knowledge of prescription writing, as many of the prescriptions are a sight to behold!

With thanks to THE JOURNAL for its many and helpful hints, I am, yours fraternally, THOS. CRUICKSHANK, M.D.

Proposed Union of the N. Y. Associations and Societies.

NEW YORK CITY, Nov. 30, 1901.

To the Editor:—I noticed, in the last number of THE JOURNAL, a communication stating that the Medical Society of the County of New York has expressed a desire to effect a union of the Medical Society of the State of New York with the New York State Medical Association.

I believe that nothing will give greater pleasure to the members of the New York State Medical Association than to give the heartiest help in furthering the union of the whole profession in the State of New York. Yours sincerely,

E. ELIOT HARRIS.

Married.

ARTHUR M. BUTZOW, M.D., to Miss Mary A. Arens, both of Chicago, November 27.

JOHN R. TUTTLE, M.D., to Miss Zine Beouy, both of Wheeling, Ind., November 20.

HENRY C. MANARY, M.D., to Miss Mary E. Johnson, both of Lincoln, Neb., November 21.

JAMES BOZEMAN BAIRD, M.D., to Mrs. Annie Raine Mynatt, both of Atlanta, Ga., November 21.

DONALD M. CAMMANN, M.D., to Miss Sophie E. Spencer, both of New York City, November 26.

MILFORD J. WHITESIDE, M.D., to Miss Molly Mabel Harris, both of Rochester, N. Y., November 20.

JOHN M. CHILDERS, M.D., Wattensaw, Ark., to Miss Leona James, of Little Rock, Ark., November 21.

ARTHUR E. SWEATLAND, M.D., Shepherd, Mich., to Miss Rose L. Altenberg, of Little Rock, Ark., December 4.

ARTHUR R. ELLIOTT, M.D., Chicago, to Miss Hannah Salisbury Fisk, at Milwaukee, Wis., November 21.

JAMES MCFADDIN DICK, M.D., Salisbury, Md., to Miss Louise Upshur Sudler, at Fairmount, Md., November 20.

WILLIAM PEYTON TUCKER, M.D., Washington, D.C., to Miss Katherine Norman, of St. Joseph, Mo., November 20.

DAYTON JOSEPH LONG, M.D., Piedmont, W. Va., to Miss Mabel Helen Shook, of Westernport, Md., November 27.

FREDERICK ROWLAND MALONE, M.D., Greensboro, Caroline County, Md., to Miss Mattie Hughlett Maylor, at Trappe, Talbot County, Md., November 20.

Deaths and Obituaries

James Polk Jackson, M.D. St. Louis Medical College, 1868, and College of Physicians and Surgeons, New York, 1873, died at his home in Kansas City, Mo., November 22, aged 56. He was a member of the American Medical Association. He established a hospital for employes of the Wabash and Missouri Pacific railways at Kansas City in 1881, and was continuously in the service of these and the Kansas City, Fort Scott and Memphis roads for many years. He filled the chair of surgery in University Medical College until 1899, when he was forced to withdraw from active teaching and became professor emeritus of that branch. The trustees of the college at a meeting held November 24, adopted the following resolutions: Whereas, It has pleased almighty God in His wisdom to remove from among us our brother in the midst of an eminent career; be it Resolved, That Dr. James Polk Jackson was a man who in his professional duties was ever faithful, conscientious, striving always to impart the latest known developments of medical science and in the most impressive manner; that our friend through his kind, sympathetic, self-respecting and reverent nature endeared himself to all who were so fortunate as to come within his influence. Resolved, That Kansas City has lost a citizen of noble type, whose heart's desire and efforts were for the uplifting of the city. Resolved, That we tender to the afflicted widow of our brother and to the immediate friends our heartfelt sympathy for the loss of one who ever held home as a sacred place and that these resolutions be embodied in the archives of the institution and a copy sent to the bereaved wife, to the daily press and to the medical journals.

Patrick S. O'Reilly, M.D. Washington University, St. Louis, 1861, died November 19, at Bay St. Louis, Miss., aged 57. He was the brother of the late Dr. Thomas O'Reilly, and was for years one of the best-known practitioners in St. Louis. He was a member of the American Medical Association. He had been ill for a long time, his illness dating from a Fourth of July accident, but the immediate cause of death was apoplexy.

John Hammond Lovatt, M.D. Sydenham College, Birmingham, England, 1861, died suddenly, aged 60, in Florence, Kan., November 23, where he had resided since 1887, two years after his arrival in America. In 1879 he was appointed a surgeon in the English army, and served for five years in India, Africa and Australia. In 1885 he was appointed a surgeon of the City Hospital at St. Louis, Mo., and served two years.

John C. Swaving, M.D. University of Giessen, Germany, 1849, a native of Vianen, Holland, but for 35 years a resident and esteemed practitioner of Pottsville, Pa., died at his home in that place, November 25, after a long illness, aged 79. At the outbreak of the Civil war he entered the Union service and served throughout the war. His service included a month's imprisonment in Libby Prison, Richmond, in 1865.

Elijah T. Collins, M.D. Medical College of Ohio, Cincinnati, 1840, died at his home in South Charleston, Ohio, October 23, aged 84. He was a native of Clark County and had practiced medicine for more than half a century. He was a member of the county and state medical societies. He leaves an estate valued at more than $100,000.

Peter Faling, M.D. Albany (N. Y.) Medical College, 1854 one of the best-known physicians in western New York, and a member of the New York State and Niagara County medical societies, was found dead in his office at his home in Gasport, November 23, aged 68. Death was probably due to an overdose of morphin.

Philo H. Banks, M.D. Jefferson Medical College, Philadelphia, died November 23 in a hospital at New Orleans, La., from typhoid fever contracted while in the employ of the British government's transport service between New Orleans and South Africa.

Thomas Langley Barnes, M.D. Missouri Medical College, St. Louis, 1851, a native of North Carolina, raised in Carthage, Ill., a veteran of the Blackhawk war, and a resident of California since 1854, died at his home in Ukiah, Cal., November 15, aged about 90.

Charles H. Hamilton, M.D. Bellevue Hospital Medical College, New York, 1869, president of the Board of Health of Newton, N. J., and town physician, died at Roosevelt Hospital, New York, November 19, two days after an operation for appendicitis, aged 54.

John J. Fanset, M.D. University of Minnesota, 1896, who immediately after graduation located in Milbank, S. Dak., died at his home in that city, November 16, from pulmonary tuberculosis, after an illness of eighteen months, aged 29.

Jefferson C. Cawood, M.D. Jefferson Medical College-, Philadelphia, 1859, one of the best-known physicians of Tennessee, died suddenly at his home in Knoxville, Tenn., November 28, while going to dinner with a party of friends, aged 71.

Ebenezer S. Johnson, M.D. a prominent physician of Maine, died at his home in Farmington, November 21, from

heart failure following pneumonia, after a brief illness, aged 61. He had practiced in Farmington for 35 years.

Arthur W. Downing, M.D. Jefferson Medical College, Philadelphia, a prominent physician and citizen of Northampton County, Va., died at his home near Bridgetown, November 21, after a short illness, aged 86.

Richard E. Edes, M.D., late assistant surgeon U. S. Navy, A. B. Johns Hopkins University, Baltimore, and M. D. Harvard University Medical School, 1895, died at Jamaica Plain, Boston, Mass., November 25, aged 32.

J. W. F. Best, M.D. University of Maryland, Baltimore, 1858, an old practitioner of Anne Arundel County, Md., and a surgeon in the Confederate army, died at his home in South River, Md., November 16.

Thomas F. McLean, M.D. Queen's University and Royal College of Physicians and Surgeons, Kingston, Ontario, 1863, a practicing physician of Conant, Fla., died suddenly at Montreal, November 17.

Charles F. Paine, M.D. University of Pennsylvania, Philadelphia, 1866, an old and respected resident of Troy, Pa., died November 14, from paralysis while on his way home from Philadelphia, aged 53.

Robert F. Bullen, M.D. Rush Medical College, Chicago, who, soon after his graduation found business life more attractive than the practice of medicine, died November 14, from heart disease, aged 54.

Joseph C. Scarborough, M.D. University of Michigan, Ann Arbor, 1898, died from pneumonia at his home in Prescott, Ariz., November 22, after an illness of three days, aged 29.

William George Wright, M.D. College of Physicans and Surgeons, N. Y., 1876, of Brooklyn, N. Y., was found asphyxiated from illuminating gas in his room, November 22.

William H. Snyder, M.D. Albany (N. Y.) Medical College, 1839, one of the oldest practitioners in New York State, died November 19, at the home of his son in Troy, aged 87.

William T. Witherington, M.D. Vanderbilt University, Nashville, Tenn., 1879, a practicing physician of Paragould, Tenn., died at a hospital in Memphis, November 18.

William R. Putney, M.D. University of Pennsylvania, Philadelphia, 1858, of New Canton, Buckingham County, Va., died suddenly November 21, at an advanced age.

Samuel I. Fox, M.,D. University of Nashville, Tenn., 1860, died recently at his home in Wills, Texas. He was a native of Kentucky, and formerly resided at Danville.

Edward Jones, M.D. Barnes Medical College, St. Louis, 1901, who had been in failing health for some time, died suddenly at Scottsdale, Texas, November 4.

Louis B. Pacetti, M.D. University of Maryland, Baltimore, 1873, died suddenly of Bright's disease, in Baltimore, November 20, aged 51.

Book Notices.

DISCIPLES OF ÆSCULAPIUS. By Sir Benjamin Ward Richardson, M.D., F.R.S. With a Life of the Author by His Daughter, Mrs. George Martin. In Two Volumes. Vols. I and II. With Portraits and Illustrations. Cloth. Pp. 424. Price, $8.00 net. New York: E. P. Dutton & Co. 1901.

This biographical work will be welcomed by all who love to learn of the old masters in medicine and surgery, and of the work they did. It is written by one who had the happy faculty of telling what he had to tell in a pleasant manner whether by voice or by pen. As a preface or introduction, is given a brief biographical sketch of the author, Sir Benjamin Ward Richardson, by his daughter. He was born in 1828 and entered Anderson's College, Glasgow, as a student in 1845, having among his fellow students one who afterwards gained renown as an African explorer, Dr. David Livingstone. During these student days he had the privilege of being one of the first in his country to witness the use of an anesthetic in a surgical operation. In 1854, after having practiced in various parts of England for short periods under different men, he moved to London. There he built up a large practice. "Sometimes I would see as many as 200 patients a day," he writes. He was one of the leaders among medical men in the cause of temperance and from his persistent labors in its behalf made not a few enemies. He was a great advocate of preventive medicine and with this in view established the *Sanitary Review and Journal of Public Health*, and later the *Social Science Review*. He was knighted in 1893 and died in 1897.

The two volumes contain the "Lives of 44 of the world's most famous physicians and surgeons; those who laid the foundation of medicine. Here is the list: William Harvey; John Keats, an Æsculapian poet; William Gilbert, Thomas Wakley, Benjamin Rush, Andreas Vesalius, Herman Boerhaave, Antony Van Leeuwenhoek, William Cheselden, Antonio Scarpa, Richard Wiseman, Ambrose Paré, John Mayow, John Arbuthnott, John Snow, John Brown, Richard Mead, John Baptist Morgagni, René Théophile Hyacinthe Laennec, William Hunter, Joseph Priestley, John Freind, Edward Jenner, Sir Francis Bacon as a Master of Physic, Alexander Monroe, William Cullen, Joseph Black, Benjamin Bell, John Hunter, William Hewson, Matthew Bailie, John Moore, Thomas Willis, Sir Kenelme Digby, Sir Thomas Browne, Thomas Sydenham, Erasmus Darwin, John Locke, Robert Boyle, Marcellus Malpighi, John Howard, William Alexander Greenhill, John Abernethy, and Thomas Young.

Some of these can hardly be classed among physicians and surgeons. While he studied medicine and was looking forward to a medical career until a little while before he died, John Keats can hardly be classed as a "Disciple of Æsculapius." Leeuwenhoek was not a physician, being noted mostly for the making of lenses and microscopes. His discovery of the capillary circulation, however, entitles him to a place among the "Disciples;" and so with several others who were not physicians, such as Joseph Priestley, etc.

Our Benjamin Rush is called the "American Sydennam," "a great as well as a conspicuous character, worthy of his time, and one of the elect of history." The author recognizes him as being a man of many-sided greatness, of high moral character, a true patriot, an orator, a philanthropist, reformer, molder of thought and a great physician. The views expressed of Rush are such as to please the most ardent admirer of the great patriot physician and show that the author fully appreciated the man and his work. The sketch of the founder of *The Lancet* is a notable tribute to a great medical reformer. During the first few years of Richardson's life in London, Wakley and he were great friends, but later with the former's connection with the *Medical Times and Gazette* there was not the same cordial feeling as before, although the two were st friends. The analysis of "Religio Medici" in the biography of its author, the erratic but versatile genius, Sir Thomas Browne, should be read by all who are interested in that peculiar book.

These biographies or lives are, as a rule, complete and contain all that is known of the subjects. Some are but brief sketches, but all contain analyses of their work and its influence on medical knowledge and medical thought. As viewed by Sir Benjamin Ward Richardson they will be found to be not only intensely interesting, but instructive also, as with two or three exceptions each of these biographies calls attention to some fact in the history of the development of our science. In fact, the history of the lives of a few dozen men, such as those in this book, is a history of medicine up to 50 to 75 years ago, Mundinus, Versalius, Harvey, and Morgagni for instance. What a rich harvest has resulted from the seed which their labors produced! The two volumes make a noble monument to one of the noblest among the disciples of Æsculapius of the nineteenth century.

AN AMERICAN TEXT-BOOK OF PATHOLOGY, for the Use of Students and Practitioners of Medicine and Surgery. Edited by Ludvig Hektoen, M.D., Professor of Pathology in Rush Medical College in Affiliation with the University of Chicago; and David Riesman, M.D., Professor of Clinical Medicine, Philadelphia Polyclinic; Instructor in Clinical Medicine, University of Pennsylvania. With 443 Illustrations, 66 of them in Color. Pages, 1245. Price, $7.50. Philadelphia and London: W. B. Saunders & Company, 1901.

The Chairman of the Section on Pathology and Bacteriology of the American Medical Association in his address at St. Paul, which address appeared in our issue of November 30,

used the following words: "The possibilities for careers in pathology and bacteriology in this country are rapidly equaling in opportunity and reward those of older countries and of other sciences in this country." The present volume is an evidence of the truth of this statement, for it shows that not a few Americans have not only chosen for themselves these careers but that they are utilizing the opportunites offered and are already making for themselves the reputation that is no small part of the reward that comes to laborers in science. Many of the collaborators are men who are devoting their entire time to the teaching of pathology and to investigations in this field and whose work is already well known. We may truly call this book American. For while, as a matter of course, a large part of the facts here recorded are obtained from non-American sources, chiefly German, it is a pleasure to note the numerous references to the original work of Americans. No book with which we are acquainted gives such a good idea of what has been done in America along pathological and bacteriological lines as this one. Heretofore a cause of no little annoyance to the honest worker has been the indifference of the continental writers to the American product, which has too often been entirely unnoticed or damned by the terse comment: "nichts neues." There is also a feeling of interest as one looks at the illustrations and finds that they are for the most part original—again an American flavor—and not the time-honored reprints whose features are so familiar.

A rather strange subdivision is that of Diseases of the Breast. We do not question Dr. Warren's ability to handle this topic or the way in which he has treated it, but where the assignment of topics is by systems rather than by separate organs it is a little out of place to make a separate chapter of twelve pages on Diseases of the Breast.

The book would be much handier if in two volumes. The one volume which with its index and advertisements contains nearly 1300 pages is too bulky.

We do not hesitate to pronounce this one of the best, if not the best, text-books on pathology and our wish would be that as it goes through succeeding editions the number of collaborators might grow smaller and that more and more of the work might be done by the capable editors or at least by a smaller corps of assistants, giving to the book greater unity and uniformity of excellence.

PEDIATRICS. The Hygienic and Medical Treatment of Children. By Thomas Morgan Rotch, M.D., Professor of the Diseases of Children, Harvard University. Third Edition, Rearranged and Rewritten. Illustrated by Numerous Engravings in the Text and by Colored Plates. Cloth. Pp. 1021. Price, $6.00. Philadelphia and London: J. B. Lippincott Co. 1901.

There is no branch of the practice of medicine of more importance than that which pertains to the management of children and the diseases to which they are subject. The physician who makes himself master of pediatrics will have a knowledge that will reach the heart, and assist him in obtaining the confidence of the most important member of the average family—the mother—and thus be the greatest aid in successfully establishing himself in the opinions of those who can make or mar his success. This is realized by every practitioner after a few years' practice—but often too late. The work before us is one that is a pleasure to recommend to those who desire a book to aid them in obtaining this knowledge. It is scientific, it is practical and will be found as helpful to the "busy practitioner" as to the student.

While the title page indicates that this is a third edition, yet it is practically a new book. The order in which the subjects were treated in former editions has been changed and much of the matter practically re-written, not a little being entirely new. Pediatrics has kept pace with the rapid advances made by other branches of the medical sciences, and this book represents this advanced knowledge. It is much more thoroughly illustrated than were the former editions, the illustrations not only being excellent ones but of remarkably practical value. Many are in colors. There is no padding and, while concisely written, clearness of expression has not been sacrificed to brevity.

Much attention is given to the anatomy and physiology of early life in the first division, which is devoted to normal development. The author's method of dealing with the subject of infant feeding—the most practical and important subject connected with pediatrics—is deserving of high commendation. The various tables for the preparation of foods, modification, sterilization, etc., of milk will be found most helpful. The paragraphs on Artificial Foods should be read by every physician in general practice, especially those who are in the habit of recommending the ready-made foods. The consideration of the diagnosis, the pathology and the treatment of the various diseases of children are in accordance and in harmony with the latest scientific methods and practice. The book is worthy of the highest commendation as a practical and scientific work in the management of children in health and disease.

A SYSTEM OF PHYSIOLOGIC THERAPEUTICS. A Practical Exposition of the Methods, Other Than Drug-giving, Useful in the Treatment of the Sick. Edited by Solomon Solis-Cohen, A.M., M.D., Professor of Medicine and Therapeutics in the Philadelphia Polyclinic. Volume I. Electrotherapy. By George W. Jacoby, M.D., Consulting Neurologist to the German Hospital, New York City. In two Books. Book I, Electrophysics—Apparatus Required for the Therapeutic and Diagnostic Use of Electricity. With 163 Illustrations. Cloth. Pp. 242. Book II, Diagnosis: Therapeutics. Illustrated. Cloth. Pp. 323. Eleven volumes. Price, $22 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This system treats of the methods to be employed in the treatment of the sick, other than by the administration of drugs. The first two volumes by Dr. George W. Jacoby, of New York, are devoted to electrotherapy. The first volume enters into the discussion of electrophysics and apparatus. The value of this volume is very much enhanced by illustrations, which serve to aid the student and the general practitioner in grasping the mechanism of the different kind of batteries, etc., although there are quite a number of useless illustrations. The second volume is devoted more especially to electrotherapeuties and contains several well-written articles on electrodiagnosis and on the treatment of many diseases as well as on the use of the current in cautery work. Skiagraphy and the Roentgen ray receive the proper attention in the first volume. There has probably never before been published so practical a work upon this subject of electricity, which at the same time is concise and complete. Dr. Jacoby deserves credit for the work contained in the first two volumes of this series.

ANATOMY, Descriptive and Surgical. By Henry Gray, F.R.S., Fellow of the Royal College of Surgeons. Edited by T. Pickering Pick, F.R.C.S., Consulting Surgeon to St. George's Hospital; and Robert Howden, M.A., M.D., C.M., Professor of Anatomy in the University of Durham. A Revised American, from the Fifteenth English Edition. With 780 Illustrations, Many of Which Are New. Cloth. Pp. 1257. Price, $5.50 net. Philadelphia and New York: Lea Brothers & Co. 1901.

This new century edition of "Gray's Anatomy" looks almost like a different book when compared with the older ones. It has been thoroughly revised, and about 60 new illustrations added, replacing some of the old wood-cuts. The newer processes of picture-making have enabled the publishers to produce differences in shading to represent curves, cavities and portions more remote, which art is an excellent aid in descriptive anatomy.

A MANUAL OF THE PRACTICE OF MEDICINE. By Frederick Taylor, M.D., F.R.C.P., Senior Physician to, and Lecturer on Medicine at Guy's Hospital. Cloth. Pp. 1028. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This book has not been received as well in this country as it deserves, but the fact that six editions have been called for shows that it has been quite popular in England. There is no attempt to cover the subjects treated in an exhaustive manner, but rather to give a short yet practical account of all the medical diseases encountered by the general practitioner. Several of the chapters have been rewritten for this editon and much new matter added, making the work accord with the present-day knowledge.

A COMPEND OF HUMAN PHYSIOLOGY Especially Adapted for the Use of Medical Students. By Albert P. Brubaker, A.M., M.D., Adjunct Professor of Physiology and Hygiene in the Jefferson Medical College. Tenth Edition, Revised and Enlarged. With Illustrations and a Table of Physiologic Constants. Cloth. Pp. 270. Price, $0.80. Philadelphia: P. Blakiston's Son & Co. 1900.

The high number of editions which this compend has gone through may be regarded as an index of the amount of information it contains. In this edition the author has revised various portions of the text and added new paragraphs.

Miscellany.

San Francisco Plague Report.

CASE 48.—Chinese, male, 37 years of age, residing at 809 Stockton St., was seen, October 19, by Dr. White, M.-H. S., City Bacteriologist Dr. Kellog, Dr. Ryfkogel and Dr. Evans. The man gave a history of being ill one week with prostration and a swelling, which was very evident on the left side of his neck. Temperature 102.5 F. at time of examination. A clinical diagnosis of plague was concurred in by the physicians present. Blood secured from an ear puncture showed the presence of numerous bipolar bacilli. The man died shortly after and an autopsy revealed general plague septicemia with enlargement of the glands on the left side of the neck; the surrounding edema was extensive, extending even to the larynx and glottis. Intestines were almost completely covered with the omentum, which was poor in fat. Appendix was normal; no fluid in cavity. Liver was visible about 1½ inches below costal border. Diaphragm attachments were on left fifth interspace; right, same. Lungs nearly met in median line; pericardial sac contained about 25 c.c. of slightly turbid fluid. Both lungs adherent at apex, no increase of fluid in pleuræ. Surface of heart was covered with fat, veins moderately dilated; the branch separating the ventricle showed numerous small hemorrhages. The right ventricle and auricle contained fluid blood. Walls of left ventricle were thicker than normal, of a dark red color and very firm. Endocardium of left heart was smooth and transparent and no thickening. A few small plaques were in aorta just above valve and near coronary opening, but they were too small to be of any consequence. Valves of heart were normal. The left lung was large and firm; pitted on pressure; crepitated freely throughout; surface was pinkish-brown color. Cut surface was poor in blood; pressure caused slight amount of blood, some serum and much air to exude. Right lung was same as left. Capsule of spleen was smooth, of a bluish slate color, showing irregular areas of capsular thickening and numerous sub-capsular nodules; organ enlarged nearly double, very soft. Cut surface was brownish-red in color, rich in blood, pulp bulging. Liver about normal in size; lower border rounded, surface smooth and glistening, color a dark-red interspersed with irregular small areas of light yellow; organ firm in consistency, cut easily without grating, cut surface rich in blood, normal except for some congestion. Fibrous capsule of left kidney stripped easily, exposing a light-red surface showing a few stellate veins; cut surface rich in blood; contrast between cortex and pyramids well preserved. Intestines were not distended, vessels of omentum dilated, mesenteric glands not enlarged. Peritoneum was normal. Stomach was normal in size; vessels of outer surface dilated. Mucosa was very much injected and hemorrhagic, in places covered with a mixture of mucus and blood. Trachea and larynx were removed en masse, also esophagus; trachea and larynx were very edematous; the larynx showed several hemorrhagic areas. Smears from the neck glands and spleen showed the plague bacillus in large numbers. Animals inoculated with emulsions of the glands and spleen died of typical plague infection.

CASE 49.—Chin Feu, Chinese, male, seen October 22 by Drs. White and Curry, M.-H. S., and City Bacteriologist Dr. Kellog, at the old Palace Hotel on Jackson Street (Chinatown). He had some trouble of the left hip-joint resembling tubercular disease and also some dulness at the apices of both lungs. He had a temperature of 101 F. and a very painful bubo in the left femoral region; pulse 120 and compressible. A clinical diagnosis of plague was made and the case seen several times afterwards. On one of these occasions, October 23, Dr. Ryfkogel made a blood count, finding a leucocytosis of 17,000. The highest temperature range in this case observed was 102.5 F.; the temperature gradually dropped, the man's health and strength improved, and the bubo gradually disappeared by resolution without signs of suppuration and he was discharged from quarantine on November 4.

CASE 50.—Fong Shing, Chinese, male, aged 35 years, died at Waverly Place and Clay Street, Oct. 30, 1901. Autopsy revealed body of a well-developed, well-nourished Chinese male. Ocular and buccal mucosa injected; cervical, epitrochlear, popliteal, left inguino-femoral and axillary glands not enlarged. The glands of the right femoral region were very much enlarged and the swelling was covered with a black tarry ointment. Over the lower chest and abdomen was a discrete, impalpable, fairly numerous petechial eruption varying in size from a pin-point to a pin-head, the larger being less distinct than the smaller and apparently older and constituting about 40 per cent. of the entire eruption. Sections of some of these petechiæ showed sharply-defined hemorrhages without surrounding edema or induration or dermal elevation or insect puncture of the skin. The heart was 11 cm. from base to apex and 9.5 cm. transversely. Epicardium of right posterior surface showed 15 to 20 small hemorrhages. Left ventricle distended by firm dark blood-clot. Two old nodules were on free border of mitral valve; heart muscle showed a distinct myositis; heart otherwise normal. Left lung was somewhat adherent to chest wall; apex showed an area about 2 cm. in diameter of caseous tubercle. Otherwise the lung crepitated throughout and contained no cavities, but was edematous. The right lung was tubercular in upper lobe and showed in one place a soft caseous tubercle about 3 cm. in diameter. Elsewhere the lung crepitated and showed no tubercular infection. Intestines were injected. The lower 1½ ft. of the ileum showed enlarged solitary follicles and a hemorrhagic mucosa; Peyer's patches were not involved. The spleen measured 16x7x3.25 cm. Trabeculæ and Malpighian bodies were distinct; pulp not bulging; consistency very friable. Stomach contained about 250 c.c. of dark yellowish-brown fluid and some solid vegetable matter. Liver measured 7x10x24 cm. Surface was smooth; there were four sub-capsular yellowish areas 3 to 5 cm. in diameter and 1 cm. thick, which on section were shown to be necrotic. Section of the liver showed some cloudy swelling. No abscesses or nodules. Gall-bladder normal. Right kidney was surrounded anteriorly and posteriorly by a well-marked hemorrhagico-gelatinous edema, most marked posteriorly. The kidney measured 9x5x3.5 cm. Capsule was slightly adherent but stripped without loss of cortical substance; cortex at thinnest part measured 0.5 cm.; vessels injected, pyramids dark, and vessels stood out prominently. The pelvis of the kidney had a few surface cysts, no hemorrhages, otherwise same as right. Both suprarenals were normal. Incision over the right inguinal and femoral regions showed a hemorrhagic and gelatinous peri-glandular infiltration, with enlargement of the lymph glands, which was most marked in the femoral region. The largest gland measured 3x1 cm. The cortex of this gland showed a few distinct hemorrhages. The sheath of the femoral vessels and the intermuscular fascia were hemorrhagic in numerous small areas. The right iliac and lumbar glands were distinctly enlarged and decidedly hemorrhagic. The abdominal hemorrhagic condition extended up about the diaphragm and over the spinal column. The bladder mucosa was injected about the neck, the urethral mucosa showed a small amount of some matter resembling an admixture of pus and semen. The fossa navicularis had four small ulcers. The epididymis and the testicles on both sides seemed free of any venereal disease. Stained smears from the bubo and the blood showed numerous characteristic bipolar bacilli. Anatomic diagnosis: bubo-septicemic plague, tuberculosis and gonorrhea. Animals inoculated with glandular tissue from the bubo died of typical plague infection.

CASE 51.—Mar Hea, Chinese, male, aged 35 years, barber by occupation. Died Nov. 4, 1901, at 22½ Waverly Place. The autopsy revealed the body of a Chinese male, of middle age. Pupils moderately contracted, rigor mortis slight. Two or three spots simulating subcutaneous hemorrhages about the neck and one on the anterior superior spine of the ileum, left (probably counter-irritation marks). Fat of abdominal wall was scanty; muscles dry. Omentum covered intestines, very poor in fat. Appendix was normal. No fluid was in abdominal cavity. Heart muscle was very soft, cut easily, showed

beginning fatty degeneration. Aorta contained several small plaques. Valves were normal. Left lung was rather small, of a mottled red and dark appearance, crepitated throughout, but was more resistant than normal. Pleura had not lost its luster, cut surface of lung moderately rich in blood, pressure caused air, blood and serum to exude. Right lung was same as left, except for a small tubercular scar in upper lobe and one small broken-down tubercle. Spleen was very friable; enlarged about one-third, surface of a bluish-red color and showed indistinct subcapsular nodules. Capsule very tense, organ very soft and cut easily, and presented marked appearance of septic infection. Left kidney capsule stripped easily, exposing a smooth reddish-yellow surface in which the venæ stellatæ were quite prominent. Cut surface was rich in blood; cortex normal in breadth. Contrast between cortex and pyramids had disappeared. Right kidney was same as left. Liver was rather small, firm in consistency; capsule glistening; cut easily and cut surface rich in blood; it showed areas of indistinct structural appearance, beginning degeneration. The intestines were injected. There was no enlargement of the lymph nodes in any region. Stained smears from the spleen showed myriads of pest bacilli. Anatomic diagnosis: Fatty degeneration of the myocardium; acute nephritis; small tubercle of left lung; acute septic spleen due to plague infection. Animals inoculated from the spleen died promptly of typical plague infection.

Burlesque Number of a Medical Journal.—The burlesque number issued by the *Muenchner Med. Wochenschrift* in honor of the anniversary of the Munich Medical Association, founded sixty-eight years ago, is just received. The make-up of the journal is the same as usual, except that the word "without" is inserted before the list of distinguished names which always adorns its cover as having promised their co-operation, and "entirely unsuited for" before the sub-head, "the General Practitioner's Organ." The advertisements include one for a resident physician for a watering place; "sole duties to say good morning to the resorters individually and sign the reports issued by the managers." A woman doctor advertises for a young colleague as assistant in cases requiring muscular strength, especially obstetric cases. The news column mentions the new titles of "Vaginalrath" and "Geheimerintestinalrath," similar to the present titles of "Sanitätsrath," etc. It is also stated that one of the Nobel prizes has been bestowed upon Professor Winer, of Giessen, for his discovery that the sensation of hunger is due to a rhythmic vibration of the stomach walls, and that these vibrations can be arrested by paralyzing the walls by the local application of his ventriculograph. This abolishes the sensation of hunger, and the organism, by a sort of auto-suggestion, feels itself satisfied and ready for physical exertion. Stations are to be established in the poorer quarters for free treatment with the ventriculograph, and it is expected to solve the social problem. A letter from an old physician, a thoroughly trained classical scholar, expresses approval of the new official regulations admitting to the medical course without a classical training. He candidly admits that the hours spent over the classics are wasted. Of what possible use to a general practitioner, he asks, is a knowledge of Greek and Latin, history or higher mathematics. He can learn by rote a few terms to impress patients with, and that is sufficient. The classics contain nothing of especial interest for the physician; Æsculapius and Galen are not used as text-books. He never finds equal-sided triangles in the human body; the extraction of square and cube roots he leaves to the dentist. Modern languages might occasionally be useful to a physician trying to practise in a large city, but even then he has to depend on the interpreters at the hotels to steer the patients to his office. The student should enter upon the medical course with his head entirely empty, allowing room for the accumulatiaon of medical lore, instead of its being crowded with useless rubbish as according to the present methods. The "practical year" now exacted of every student in Germany, should precede instead of following the medical course. The student would then be able to ascertain exactly what knowledge he would need in his practice and thus be able to study only those things which will be of use to him.

Connection Between General Paralysis and Syphilis.—Under the heading "Nosologic Proof of the Causal Relations Between Syphilis and Progressive Paralysis," Muratoff reports in *Russky Archiv Patologie*, xii, 1, a case in which the incipient symptoms of progressive paralysis appeared simultaneously with tertiary syphilitic manifestations in the spinal cord, cortex and ventricles. Parasyphilitic symptoms were also observed.

Osteopathy Treatment.—What is the kernel of therapeutic truth in osteopathy? Simply that the more or less judicious movements of diseased parts cure such parts. This fact is demonstrated by the position of the Ling system in Swedish medicine, by the cures wrought among us by the imported masseurs and their imitative rubbers, and by the great popularity of osteopathy among the laity. What is the harm of it? The harm of it is its indiscriminate application as a "cure-all"—a system of cure—by its enthusiastic but poorly educated leaders. What is the profession doing to reclaim this lost territory to its own? With us the little done is left to the untrained or the imported. Nothing is done to popularize the method, and this remedy of undoubted therapeutic value is wholly neglected in our smaller communities. The time is ripe for a well-officered and well-equipped school of massage and physical culture.—N. W. *Lancet.*

Antisepsis versus Asepsis.—Lucas-Championnière, president of the French Association of Surgery, in his address at the meeting in October, deplored the too general neglect of antisepsis for the less reliable asepsis. His conclusions are the following: 1. Moderation in the use of antiseptics in the surgery of the abdominal viscera; in the intestine, stomach and kidney, antiseptics are less useful and more injurious than in other operations. 2. Antiseptics should be used in all laparotomies where there is the least apparent presence of sepsis. 3. For all operations outside of the abdomen, antiseptic surgery is the only certain procedure. 4. In hospital work, antiseptic surgery remains the only method which gives sufficient guarantee of definite security in all operations. He adds: "As for myself, the use of carbolic acid, hydrogen peroxid, and in a small measure, iodoform appear to answer the chemical desiderata."

International Congress of Life Insurance Examiners at Amsterdam.—Among the communications presented we note that Weill-Mantou would postpone every candidate for life insurance with an existing focus of tenderness in the region of the appendix or a previous history of the kind, who has not been operated. An operation removes the obstacle to acceptance, after an interval varying according as the operation was performed "hot" or "cold." Burger would exclude all cases of purulent chronic otitis of the middle ear when complicated by inflammation of the attic or antrum, when it is tuberculous or cholesteatomatous or accompanied by a lesion of the bone, facial paralysis, vertigo or cephalalgia. All other varieties can be accepted as extra hazardous risks. Acceptance should be postponed until after recovery from acute otitis. Bilateral deafness, severe auricular vertigo and also permanent perforation of the tympanum require an increased rate. Crocq proclaimed that the absolute extinction of the knee-jerk should exclude the candidate, and its partial abolition should entail more careful scrutiny of the other functions of the nervous system. If exaggerated, the candidate should be refused if evidences of an organic lesion can be discovered. If merely a functional neurosis exists, the prognosis varies with the individual case. Insurance should be refused in case of the abolition or pronounced weakening of the pupil reflexes, Argyll-Robertson's sign and inequality of the pupil, Babinsky's sign and a tendency to clonic contraction on the part of the tendons. Moritz and Poels would reject all applicants in the early stage of arteriosclerosis. The insurance should be limited to a certain age in case of established arteriosclerosis, and the candidate refused if the heart shows signs of weakness. In case of heart disease, long survival is possible in case of perfect compensation that has lasted for five years at least, with the heart affection latent during this period. Compensation is more liable to be permanent in case of insufficiency than in case of

stenosis. The prognosis of aortic lesions is more favorable than of mitral and pulmonary and of lesions of the pericardium than of the endocardium and pericardium. After 50 years of age the candidate should be rejected. Stokvis excludes persons with a renal affection, but does not consider extrarenal albuminuria a contraindication. He noted an extrarenal cause in 60 per cent. of 21 candidates exhibiting albuminuria. Statistics show that the mortality from affections of the bladder or prostate is only 1.5 per cent. of the general mortality, and six-sevenths of these deaths occur after 60. In determining the existence of a renal lesion, permanent albuminuria is less significant than the concomitant symptoms, hypertrophy or dilatation of the heart, polyuria, pollakiuria, etc. In functional albuminuria of cardiac origin, the condition of the heart is the principal element in the decision. Periodical functional albuminuria is no contraindication to acceptance. Siredey definitely rejects all diabetics under 35. After this age if the general appearance is good, all the organs sound, with the apices normal, and the candidate does not live in contact with consumptives, he can be accepted with an increased premium. In case of nervous diabetes, resulting from emotions, trauma, over-exertion, excesses, the age and general appearance are less reliable for the prognosis. Candidates of this category should be postponed for six months and not accepted unless a later examination is more favorable.

Should Students in the Upper Grades Be Enlightened in Regard to the Dangers of Venereal Diseases?—This subject has been under discussion in the newly-organized French Society of Moral and Sanitary Prophylaxis. Fournier, in an article in the *Gaz. Hebd.*, No. 20, strongly advocates the necessity of special instruction in this line. The age between 16 and 19 affords a large percentage of all cases of venereal diseases, and youth should be enlightened in regard to their dangers. This instruction could be imparted without offense to morality by one of the teachers or by a physician, and all the scholars over 16 in educational institutions should be thus enlightened.

Societies.

COMING MEETINGS.

Western Surgical and Gynecological Association, Chicago, Dec. 18-19, 1901.

Harrisburg (Pa.) Academy of Medicine.—The sixth anniversary of the Academy was held, November 22. The orator of the evening was Dr. William Osler, Johns Hopkins University, Baltimore, who spoke on "Pulmonary Tuberculosis."

Tri-County Medical Society of Montery, Santa Cruz and San Benito Counties (Cal.).—A meeting of physicians was held at Salinas, November 20, for the purpose of forming a tri-county organization. Dr. Edward C. Thomas, Salinas, was elected temporary chairman, and Dr. Pope, Watsonville, temporary secretary.

Medical Association of Hawaii.—The meeting of this Association was held at Honolulu, November 4, when the following officers were re-elected: Dr. W. E. Taylor, president; Dr. H. C. Sloggett, vice-president; Dr. A. Gorgon Hodgins, secretary and treasurer, and Drs. Robert P. Meyers and Charles B. Cooper, executive committee.

Petersburg (Va.) Medical Faculty.—The annual meeting and banquet of this organization was held November 22. Dr. Daniel W. Lassiter was elected president; Dr. Frank W. Hains, first vice-president; Dr. William Shippen, second vice-president; Dr. Robert D. McIlwaine, corresponding secretary, and Dr. Joseph D. Osborne, recording secretary.

Mahaska County (Iowa) Medical Society.—The organization of this Society was perfected at Oskaloosa, November 20, by the adoption of a constitution and by-laws, and the election of the following officers: David A. Hoffman, president; Dr. Joseph T. Coveny, vice-president; Dr. Lewis A. Rodgers, secretary, and Dr. Samuel W. Clark, treasurer, all of Oskaloosa.

Inter-Urban (West Superior, Wis., and Duluth, Minn.) Medical Association.—The annual banquet and meeting of this body was held at West Superior, Wis., November 20. Dr. William E. Ground, West Superior, was elected president; Dr. Alfred E. Walker, Duluth, vice-president; Dr. Patrick G. McGill, West Superior, secretary and treasurer, and Dr. George H. Conklin, West Superior, censor.

Middle Tennessee Medical Society.—The fifteenth semi-annual convention of this Society was held in Fayetteville, November 21 and 22. Dr. George W. Moody, Shelbyville, was elected president; Dr. Leonidas L. Sheddan, Williamsport, vice-president, and Dr. Frank B. Reager, Shelbyville, secretary and treasurer. A proposed amendment to the constitution that the Society be made a branch of the Tennessee Medical Association was postponed. The next meeting will be held in Lewisburg.

Western Surgical and Gynecological Association.—The twenty-first annual meeting of this Association will be held at the Great Northern Hotel, Chicago, on Wednesday and Thursday, December 18 and 19, 1901. The following papers will be presented:

An Old Shoulder Luxation, with Report of a Case; Illustrated. J. Rudis-Jicinsky, Cedar Rapids, Iowa.

The Operative Relief of Impaired Function of the Elbow-Joint Due to Epiphyseal Displacement. G. G. Cottam, Rock Rapids, Iowa.

Complete Dislocation of the Astragalus, with Presentation of a Case. Wm. Jepson, Sioux City, Iowa.

Some Internal Injuries of the Knee-Joint. M. L. Harris, Chicago, Ill.

Treatment of Dislocation of Clavicle Through Open Wound. J. E. Moore, Minneapolis, Minn.

Etiological Factors in Production of Tumors. Geo. Halley, Kansas City, Mo.

A Consideration of the Different Surgical Procedures in the Removal of the Fibro-myoma of the Uterus. Joseph Eastman, Indianapolis, Ind.

Myomectomy: Its Place in the Treatment of Fibro-myoma of the Uterus. O. Beverly Campbell, Chicago, Ill.

Management of Fibro-myoma of the Uterus Complicated with Pregnancy. Miles F. Porter, Ft. Wayne, Ind.

The Present Status of the Electrical Treatment of Fibro-myoma of the Uterus. Franklin H. Martin, Chicago, Ill.

Two Cases of Cysts of the Broad Ligament Complicated with Myxoma. Edw. Hornibrook, Cherokee, Iowa.

Diffuse Sarcoma of the Uterus. D. S. Fairchild, Clinton, Iowa.

The Misleading Significance of Ovarian Pain. C. Lester Hall, Kansas City, Mo.

The Use of the Gall-Bladder as a Suspensory Ligament for a Prolapsed Liver. A. F. Jonas, Omaha, Neb.

Heart Suture. B. Merrill Ricketts, Cincinnati, Ohio.

A Simple Method of Extension in Fracture of the Metacarpal Bones, and Oblique Fracture, Simple or Compound, of the Forearm. W. W. Grant, Denver, Colo.

Some Observations Made in Europe. J. P. Lord, Omaha, Neb.

SYMPOSIUM ON PROSTATECTOMY.

(*a*) A General Review of the Subject, with Special Reference to Total Extirpation of the Gland Through a Median Incision in the Perineum. Alex. Hugh Ferguson, Chicago, Ill.

(*b*) Symptoms, Signs, Diagnosis, Prognosis and Palliative Treatment: (*a*) Massage; (*b*) Aspiration; (*c*) Catheterization; (*d*) Dilatation, and (*e*) Cystotomy. Lewis Schooler, Des Moines, Iowa.

(*c*) The Etiology and Pathology of Prostatic Hypertrophy and Suprapubic Drainage as a Method of Treatment. A. C. Bernays, St. Louis, Mo.

(*d*) Suprapubic Prostatectomy. C. H. Mayo, Rochester, Minn.

(*e*) The Indications and Limitations of the Bottini Operation. Louis E. Schmidt, Chicago, Ill.

The Operation of Selection in Retroversion of the Uterus. J. Clarence Webster, Chicago, Ill.

Hemostasis of the Broad Ligament. Henry P. Newman, Chicago, Ill.

Septicemia and Its Treatment. J. W. Macdonald, Minneapolis, Minn.

How Shall We Treat Sepsis Following Labor and Abortion? W. O. Henry, Omaha, Neb.

Non-malignant Neoplasms of the Larynx, with Report of Cases. J. B. Murphy, Chicago, Ill.

Stricture of the Esophagus. B. B. Davis, Omaha, Neb.

Intestinal Obstruction from Meckel's Diverticulum, with Report of a Case. A. E. Halstead, Chicago, Ill.

Tri-State Medical Association of Mississippi, Arkansas and Texas.—The eighteenth annual meeting of this Association was held in Memphis, Tenn., November 19, 20 and 21. Dr. William Britt Burns, Memphis, Tenn., delivered the Address in Medicine, and Dr. Joseph P. Runyan, Little Rock, Ark., the Address in Surgery. The following officers were elected: Dr. James B. McElroy, Stovall, Miss., president; Drs. H. L. Sutherland, Rosedale, Miss., William C. Dunnaway, Little Rock,

Ark., and L. A. Yarbrough, Covington, Tenn., vice-presidents; Dr. Richmond McKinney, Memphis, Tenn., secretary, and Dr. Marcus Haase, Memphis, Tenn., treasurer.

Boston (Mass.) Medical Society.—The fifth annual banquet of this Society was held at Young's, November 19. Dr. Rufus K. Noyes was elected president; Dr. William A. Butman, secretary; Dr. Warren F. Gay, financial secretary, and Dr. Israel J. E. Shapira, treasurer. The president gave an interesting talk on the evolution of medical science and of the medical practitioner. Henry Canning, one of the oldest pharmacists in the city, spoke entertainingly on the relations between the pharmacist and the physician, and Dr. Patrick F. Kelleher, who, besides being a physican, is also a member of the Suffolk bar, gave with the aid of a manikin a very interesting demonstration of his new obstetrical axistractor.

NEW YORK OBSTETRICAL SOCIETY.

Stated Meeting, held Nov. 12, 1901.

Dr. Malcolm McLean in the Chair.

Cancer of the Ovary.

Dr. W. S. Stone gave the history of the patient and exhibited specimen. Mrs. B., admitted to the General Memorial Hospital, Oct. 14, 1901, age 47; married 26 years; ii-para. Last child was 23 years ago. Both labors and childbeds were normal. No miscarriages. She has always menstruated profusely every month, 12 to 15 days, and accompanied by pains on the right side of the lower abdomen. Her general health has failed, and lately there has been a brownish vaginal discharge between the periods. Upon admission to the hospital she was very pale and somewhat emaciated. The cervix was rather large, hard and nodular. External os admitted one finger; internal os, the tip of the finger. The uterine body felt enlarged, and slightly retroverted and turned to the left. There was behind and to the right a rather hard, globular mass, which felt to be about the size of a grape fruit. It was close to the uterus and seemed to be adherent to it, as they both moved together slightly. A diagnosis was made of cancer of the uterine body, either with a separate tumor, or with a cancerous involvement of the right broad ligament.

An operation was made Oct. 19, 1901. The uterus and tumor were removed from above. The tumor was found to be a separate affair, and presented the only difficulty in the operation because of its firm union with the rectum. The patient quickly rallied from the operation and made an uneventful recovery. The uterus was considerably enlarged and extremely hard. There presented in the left horn a small, ragged growth, which in the fresh state was very soft and brain-like. Its histological structure was that of an adenoma, or the so-called malignant adenoma, or, perhaps, better, an adeno-carcinoma. The tumor was a solid one of the right ovary, and measured in its fresh state 8 by 9 centimeters. Its cut surface was rather homogeneous in appearance, and its outer surface, although slightly irregular, conformed in general to the ovarian shape. There were some softened areas, which proved histologically to be necrotic tissue. In many places, however, it presented the typical picture of carcinoma. A portion of its surface that had been adherent to the rectum was in a condition of almost purulent inflammation, as shown by the small, round-cell infiltration. The right tube, as well as the left tube and ovary were normal.

Dr. Herman J. Boldt said that the specimen exhibited by Dr. Stone showed the relationship that had been pointed out a number of times by various writers between malignant disease of the body of the uterus and malignant disease of the ovary and, for that reason, he had always advised performing a radical operation for cancer of the uterine body and removing the ovaries because of the not infrequent involvement of these glands.

Dr. J. Riddle Goffe believed, too, that the specimen seemed to show a relationship between cancer of the body of the uterus and cancer of the ovary. The disease was more extensive in the ovary than in the uterus, and, to that extent, the inference would be that it began in the ovary. He was inclined to think, however, that there were two spontaneous foci here, with no relation between them whatever.

A New Operation for Retroversion of the Uterus.

Dr. J. D. Bissell gave a description of a new operation for retroversion of the uterus, and presented a patient upon whom he had performed the operation. The procedure adopted is as follows:

The abdomen is opened in the median line. If pelvic adhesions exist they are broken up and the attached organs are freed, and if the tubes or ovaries are diseased they are removed. The uterus is then grasped at the fundus with the vulsellum forceps and pulled upward. In order to form an exact idea of the extent of relaxation in the round ligament, a suture, on a small round-pointed needle, is first passed from behind forward through the round ligament at a point one-half an inch from its attachment to the uterus; the same suture is again passed, but in an opposite direction, through the round ligament at a point about one inch from the first insertion. A similar procedure is followed on the other side. When these temporary sutures are tied the round ligaments become looped and an exact idea is formed as to the amount of round ligament to be resected. If the tension on the ligament is found to be too great the section is made inside the loop. If not sufficiently taut the section is made outside the loop. Another preliminary but essential step is to pass a suture immediately under the round ligament about one-half an inch and to the outer side of the loop. This, when tied, completely encircles the round ligament and prevents its end from retracting when the section is made. It also facilitates the handling of the ligament when introducing the permanent sutures. The same step is taken on the other side of the loop about one-quarter of an inch from the uterus, but the latter is not so essential as the former. A section of the round ligament is then made inside or outside the loop as is found necessary. The temporary suture forming loop is then cut and this section of the round ligament is dissected away from the broad ligament. The artery of the round ligament is grasped and tied, if severed. The next step is the insertion of the permanent sutures and the adoption and adjustment of the raw surfaces. The first suture is passed on a round-pointed needle from above downward through the center of the round ligament, and then through the other cut end, from below upward. Two other sutures of the same size are passed, one on each side, but only half-way through the ligament, which serve, when tied, to keep the ends in exact position. The sutures in the round ligament are not tied until the raw surface of the broad ligament made by cutting away the resected portion is disposed of. This raw surface is parallel with the course of the round ligament, but is sewed together with No. 1 catgut on a line at a right angle to its original direction. The suturing of this surface should be done before the round ligament sutures are tied and in the following way: With a tissue forceps grasp the broad ligament on the under surface midway. A suture is passed at this point and continued along the denuded edge to the middle of the opposite side. It will be found that the suturing of the broad ligament in this way brings the ends of the round ligament into close apposition. The permanent sutures that have been passed through the ends of the round ligament are then tied and the operation completed.

The following is a brief history of the first case operated on. Mrs. S., 30 years old; operation September 3; curettage and abdominal section. There was complete retroversion, slight adhesion about the right ovary and tube. Symptoms before operation were "pulling and dragging in the bones of the back," pain through the pelvis of such a character as to prevent her from walking or standing with ease; more or less tenseness of the bladder. Menstruation was very free, sometimes lasting twenty days. Two and a half months after operation the uterus is found in perfect position. She had menstruated twice, eight days at each period. She is relieved of all pain and discomfort.

Dr. W. Gill Wylie had examined Dr. Bissell's patient and he found the uterus in good position. The broad ligament was shortened and pulled the uterus up and forward. He preferred this operation to the operation attaching the uterus to the anterior abdominal wall, which he does not now do except

very rarely in women past the menopause. Beyond the required skill to get the ends of the round ligament together he could see no special objection to the operation. His preference, however, was for the Alexander operation, attaching the cord near the end of Poupart's ligament, where we get firm union by white fibrous tissue of the cord and Poupart's ligament. He thought that Alexander's operation covered the field.

Dysmenorrhea, with Special Reference to Its Occurrence in Nulliparae.

Dr. William R. Pryor, in this special topic for discussion, thought that we may classify these cases according to their symptoms or according to the local pathology, although the latter is but little understood. Confining his remarks to dysmenorrhea not due to disease of the ovaries and tubes, he stated his belief that many of the cases were due to errors of development and others to changes which take place with advancing years. In the first class of cases he found usually associated with dysmenorrhea errors or irregularities in development of other parts of the body. We could understand how this would be so in the light of our knowledge that the endometrium was not a mucous membrane, but a part of the great lymphoid chain. Conditions similar to the congenital ones may be brought about by sterility, for an organ which should have two years' rest from a routine menstruation and receive those benefits which follow the essential structural changes incident to conception and delivery, must undergo some modification in its structure. We find these changes associated with and not caused by various distortions of the cervix and of the body of the uterus. He was in the habit of taking a little broader view than the one laid down in our books. He tried to build these patients up if they needed it. If plethoric patients, he regulated the diet to meet that condition; if gouty he treated that, etc. His local treatment was based upon the supposition that he had to deal with a malformed or degenerated endometrium. This was sometimes hypertrophied and sometimes atrophied. He always, if he operated at all, performed a curettage in such a way as to promote the formation of a new histological endometrium. If the cervix was hypertrophied, he either amputated or incised along the lines of Simpson, Sims, or modification of Dudley. If the cervix was merely stenosed, incision was sufficient. He said it was needless to go into the technique of these several operations or their particular indication. So far as nonoperative cases were concerned, he got the best results from gelsemium and cannabis indica if the flow was too free, or with hyoscyamus if hysteric symptoms were marked. He always avoided the administration of the coaltar derivatives and of the opium compounds. If the patient was married he expected in the line of treatment conception, which he believed to be the radical cure. The wearing of stems and repeated dilatations he considered mischievous.

Dr. Herman J. Boldt shared, to a great extent, the views expressed by Dr. Pryor, and treated patients suffering from dysmenorrhea variously. Many times patients suffer from dysmenorrhea when no pathologic condition can be found in the pelvis, and he was at a loss to account for the causation of such cases.

Dr. Henry C. Coe said that while he was inclined to agree with Dr. Pryor in believing that so-called "obstructive" dysmenorrhea could not always be explained satisfactorily by reference to the mechanical theory, he could not subscribe to his statement that disease of the endometrium was the only cause, for it seemed to him that the evidence, both clinical and anatomical, was opposed to that view. Often in these cases the vigorous use of the curette fails to show the presence of a hyperplastic endometritis, and even when the anteflexed uterus was examined after removal intra vitam or at autopsy, such marked evidences of disease as would account for the painful symptoms is seldom found. On the other hand, all had had experience with the Dudley operation and have seen the dysmenorrhea cured by permanently straightening the canal. He would emphasize the fact that many cases in which painful menstruation was apparently due to flexion were by no means as simple as would appear from the results of examination. He thought the subject was too broad to be discussed only from the standpoint of mechanical obstruction or disease of the endometrium.

Dr. W. Gill Wylie said that he held the same views regarding dysmenorrhea to-day that he held seventeen years ago, when this subject was the text of almost his first paper. He then took the ground that the real cause was dysmenorrhea due to imperfect development; that the membrane, especially in the young women of the better class, was not nourished sufficiently to become a normal living membrane; that it was deficient in blood supply, weak and feeble, and the easy prey of disease; therefore, when the function of menstruation began it could not be performed normally. He confessed that he was unable to state just what the exact pathologic condition was, that it was a chronic form of endometritis, causing excessive hyperesthesia. His definition of dysmenorrhea was that it was a pain just before or during the menstrual flow and his own test for the condition was as follows: If a nulliparous woman complains of pain before menstruation, or after it begins during the flow, the uterus will, as a rule, be found abnormally small, especially about the cervix and at the os internum, and if active disease be excluded, you will always find present an anteflexion. He did not think that any mere mechanical act of opening the canal would have much to do in overcoming the difficulty. The patient he placed in the Sims position, and a small silver probe, the same kind that Dr. Sims used, was passed. If that woman was suffering from dysmenorrhea, almost without exception the passing of that silver probe will cause pain, especially when the probe reaches the os internum; at this point the tissues are extremely sensitive. He considered this test almost pathognomonic. Given such a case in a woman who is well, whose general health is fair, with an atrophied and extremely imperfectly developed uterus which does not extend to the ovaries and other generative organs, it was his experience that if you thoroughly divulse and produce a fair amount of dilatation and splitting the muscular tissue and tearing them, good results would follow. He was satisfied that one-quarter to one-half an inch separation of the blades of the dilator, with not less than 200 pounds pressure, would accomplish good results. The old method of claiming that one to one and a half divulsion was wrong and was only apparent and not actual unless the whole muscular structure at the os internum was torn through. He never used violent mechanical power. After divulsing the canal he ran over the surface of the endometrium with a curette if indicated, and then placed in a hard-rubber drainage tube the size of a lead-pencil; this tube has a somewhat bulbous conical end with a slot, which takes up fully one-third of the caliber of the tube; it has a round button-shaped end in the vagina. In some cases he thought that curettement was very useful and essential where there are pathologic conditions to deal with, but, in many instances, curettement does not bring away very much. He claimed that even a thorough divulsion would not give lasting results, relief being experienced but a short time. His experience had taught him that when we dilate and use a hard-rubber drainage tube, keeping the os internum open for a week or more, a great many cases would be cured, but a large percentage would not be cured. By accident he found that the tube could be left in through one menstruation and then, as a rule, should be taken out. In obstinate cases the tube could be left in through two menstruations without danger and the patient could go about. In very many cases of imperfect development this operation would give results which lasted three, four and even six months; but in typical severe cases there was likely to be a return of the trouble. One should give time for the organ to grow, and so in these extreme cases the procedure may have to be repeated three times. He said that if to-day he got 10 cases of dysmenorrhea in patients all under 23 or 24 years of age, he would expect to cure not less than 9 out of the 10. He had treated several hundred of these cases without the slightest accident or serious consequences from the use of the tube so far as he knew. Formerly he used gauze in the vagina to keep the drainage-tube in place, but a hard rubber Albert Smith pessary was much better and was essential when the

tube was worn during menstruation. This method had been of much value to him in caring for women who were sterile; in such cases, uncomplicated by occluded tubes, gonorrhea, etc., good results frequently follow this treatment. He had used this method during the past twenty years, and the only change he had made was in perfecting his method.

Dr. J. Riddle Goffe said that the imperfectly developed uterus as one of the principal causes of dysmenorrhea had been one that has dominated his treatment, and his experience justified him in assuming that in all cases where dysmenorrhea began with the first menstruation, they were invariably cases of imperfect or faulty development. There was another class of cases, women, nulliparæ and multiparæ, who had been free from pain in the early history of menstruation and later develop dysmenorrhea. These patients were the victims of some pathologic lesion and almost invariably, in his experience, it had been due to an infection from gonorrhea, either an endometritis, salpingitis or an ovaritis, and sometimes all three together. When the latter condition existed the method of procedure was clear and the results in the hands of all present had been, he thought, satisfactory in the way of cure so far as the dysmenorrhea was concerned.

In the first class of undeveloped uterus there was a lack of development not only of the uterus itself, but also of the tubes and ovaries and of the whole circulatory apparatus. To accomplish a permanent result the treatment must be continued throughout a long period of time, one or two months, and, in extreme cases, dilatation and curettage under an anesthetic, followed not by the use of the hard tube, but of the gauze pack. If a patient comes to his office suffering from dysmenorrhea she will usually be found to be sterile, and he always insists that she shall place herself under his care for at least three months. Then, under careful antiseptic precautions in the office, he dilates the cervix and makes an application of pure carbolic acid to the internal os and the interior of the uterus. If, after two or three treatments, he finds no indications for any change of treatment he continues to treat her twice a week for three months. At the end of that time he tells her that he does not wish to see her again for three months and it had been his experience in a number of cases to find that when she again returns she will give a history of having skipped a period and it eventuates that she is pregnant. If, though, she still complains of pain, he continues to treat her for another three months. If the first course of treatment is without benefit he advises a more radical treatment, and, under an anesthetic, he thoroughly dilates the internal os, curettes the interior of the uterus, and, instead of using a hard-rubber tube, he packs the uterus with gauze, which acts as a foreign body and so stimulates contractions. The uterus being a muscular body, is developed by exercise, and in the efforts of that organ to expel the gauze packing the walls of the uterus in all its muscular structures are strengthened and developed and the circulation improved. The gauze is left in place for four days, at the end of which time in all cases he finds more or less of the gauze expelled from the uterus, which shows that there has been strong muscular contractions. His object was not only to develop the muscular structures, but also to stimulate the circulation not alone of the uterus, but of the entire generative apparatus.

Dr. W. Evelyn Porter believed that the form of drainage to be used in these cases should be judged according to each individual case. If there was a large uterus he agreed with Dr. Goffe that sometimes the mere packing that organ with gauze would be productive of good results, but the objection was that there was not sufficient drainage which was so essential, as, in nearly every instance, there was more or less increase in the secretion which must be drained; therefore, he had found that when the gauze was left in a sufficient length of time to produce the desired effect that it obstructed rather than drained. He had had a few cases where the slot in the drainage tube referred to by Dr. Wylie had become obstructed by blood clots and mucus, and, in order to overcome this obstruction, he had had made a stem with a device for flushing out the slot without the necessity of its removal.

Dr. Hiram N. Vineberg said that in the slighter degrees of arrest of development, where we meet with a long, narrow cervix and a moderately sized body sharply anteflexed, dilatation and curettage were of decided benefit, and in this class of cases he had found the employment of the cervical stem gave better results than where dilatation and curettage alone had been employed. It was his custom to remove the tube and irrigate the uterine canal with a glass catheter and then reintroduce it and leave it in for one week or ten days. In this class of cases he had several times performed the Dudley operation with a fair amount of success. No treatment had been of service in that other class of cases where the uterus was found in the form of a congenital retroversion of about the second degree. If these patients marry, menstruation almost always ceases, which is different from what we expect; the stimulation of married life seems to have the opposite effect: menstruation ceases or else occurs once in five or six months. In some cases he had found the intrauterine application of galvanism had been productive of good results, 25 milliamperes being used; sometimes these patients will remain well for two or three years.

Dr. Joseph Brettauer was astonished at Dr. Wylie's statement that he had cured 9 out of 10 of these cases, for he had been so far decidedly unsuccessful, even when using the method described by him. About two years ago he saw a book entitled "Nase und Weibliche Geschlechts-organe," by Fliess, in which was reported a number of cases of dysmenorrhea cured temporarily and permanently by the application of cocain to certain parts of the nose. No explanation was needed as to why the book did not impress him greatly at the time, but when, however, one year afterward an article appeared in the *Wiener Klin. Wochenschrift*, corroborating in substance what Fliess had maintained for several years, he decided to go into the matter seriously. The observations described in the latter article were made at Chroback's clinic in Vienna, and knowing from personal connection with this clinic the conservative spirit with which it was directed, doubt was out of the question. According to Fliess, the anterior half of the lower turbinated bone and the tuberculum septi of the nose were the points which were in some way connected with the genital organs, and this was proven by the cocain test, followed in proper cases by cauterization. The speaker's personal experience so far was limited, and not uniformly satisfactory. The cases of dysmenorrhea in which other efforts had failed were benefited by the application of cocain to the nose, but, so far, his successes were fewer than the failures; still he was of the opinion that the subject deserved close attention and trial.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Regular Meeting, held Oct. 21, 1901.

The President, Dr. Parker Syms, in the Chair.

Dr. Heinrich Stern exhibited a new percussion mallet, and demonstrated its action upon a patient. It is actuated by a spring after the manner of the well-known dental mallet, and a pleximeter, in the form of a small disk, is permanently attached to its distal end. Aside from the convenience of having hammer and pleximeter in one piece, an advantage claimed for this instrument is that its strokes are uniform in both force and duration.

Dr. J. W. S. Gouley presented a new retractor that he had devised for use in connection with enucleation of the prostate. The instrument is introduced with the beak looking upward, but after it has reached the bladder it is reversed.

Fibroid Tumor of the Fallopian Tube.

Dr. J. Riddle Goffe exhibited a rare specimen. The tumor was upon the left tube, about three-fourths of an inch from the horn of the uterus. It had been taken from a young woman who had suffered for many years from dysmenorrhea. The fimbriated extremity of the other tube was found sufficiently open to admit the thumb, and protruding from this opening was a cyst of Morgagni. Dr. Goffe said that he had only found one case of this kind on record, and that had occurred in the experience of Jacobs, of Brussels.

Dr. A. Palmer Dudley said that he had seen only one fibroid tumor of the Fallopian tube in his whole experience,

though he saw no reason why the same conditions which give rise to fibromata in the uterus should not produce fibromata of the tubes. These tumors were just as apt to occur in the young woman as in those near the menopause.

DR. FREDERICK HOLME WIGGIN said that he had never before seen a case of this kind.

DR. A. BROTHERS said that this had also been his experience, but he had met with two fibroids of the ovary.

Spasmodic Affections of the Larynx.

DR. EMIL MAYER said that rachitis stood at the head of the list of causal factors, but other common causes were dentition, enlarged glands, inflammation of the air passages, disturbances of digestion and an excess of lymphoid tissue. Unless the attack was due to direct cerebral irritation the prognosis was good. Death sometimes occurred from asphyxia, heart failure or cerebral compression. Attention to the diet and general hygiene of the child would do much towards ameliorating the condition, and chloral and the bromids would be found useful in the treatment of the attack. While laryngeal spasm was much less frequent in adults it might arise in connection with hysteria, chorea, epilepsy, tetanus, hydrophobia and tabes. A very interesting form of spasm of the larynx was that known as laryngeal vertigo or laryngeal epilepsy. Asthma, excessive smoking, hypertrophy of the uvula and of the lingual tonsil, and tabes were among the prominent causes. The attack simulates an epileptic seizure, but may be differentiated therefrom by the tongue not being bitten in laryngeal vertigo, and by the absence of involuntary defecation, of headache and by an almost entire absence of muscular spasm. The speaker described stammering as the result of the inco-ordination of the three mechanisms of speech, the respiratory, the vocal and the aural. For some reason, as yet not satisfactorily explained, fully 95 per cent. of stammerers are males. By gentle and persistent effort physiologic voice sounds should be taught, and the extrinsic muscles brought into proper action. In this way a cure could usually be effected.

DR. FRANCIS J. QUINLAN said that upwards of 85 per cent. of cases of spasmodic affections of the air-passages occur in children. He was disposed to minimize the effect of intestinal disorders. A most careful search should be made for accumulations of lymphoid tissue, for hypertrophied tonsils and for other abnormalities of the upper air-passages.

DR. WILLIAM M. LESZYNSKY said that the spasmodic affections of the larynx which are of special neurologic interest arise in patients who are the subjects of hysteria, chorea, epilepsy or locomotor ataxia. The laryngeal spasm, occurring in local affections of the larynx, was usually the result of direct irritation of the terminal nerve distribution in the larynx itself. The type seen by the neurologist, however, was usually due to some form of irritation of the pneumogastric nerve or the recurrent laryngeal branch, and was either of central or reflex origin. Children were more predisposed to spasm, on account of their inherent reflex irritability. It had also been frequently noted that spasm of the glottis in children bears a close relation to tetany, which is so commonly associated with rachitis. In the more severe forms of hysteria, spasm of the glottis might occur in violent paroxysms, and the patient might appear to be on the point of death by suffocation. It was usually accompanied by other spasmodic or convulsive symptoms. Although of very rare occurrence, it was not without danger, and on account of the condition threatening life, tracheotomy had been performed. A subcutaneous injection of apomorphin, however, generally proved successful in relieving the spasm. The so-called laryngeal epilepsy, or laryngeal vertigo, was a very rare condition, and might be classified as a reflex neurosis. It was characterized by a paroxysm of coughing, followed by sudden dyspnea, syncope, and slight convulsive movements, the patient falling unconscious for a short time. It occurred chiefly in males between 40 and 50 years of age.

DR. J. H. WOODWARD spoke of laryngismus stridulus, a spasmodic affection of the larynx only found in children. It was closely associated with rickets, and was best treated by the bromids and tonics, together with hygienic measures.

DR. C. E. QUIMBY alluded to a form of spasmodic affection of the larynx commonly observed in persons who had indulged a good deal in drinking before retiring at night. He said that his experience had led him to believe that this was dependent upon cardiac exhaustion.

DR. A. C. WAY, Perry Center, remarked that he had found attacks of spasmodic croup yield very promptly to injections of nitroglycerin.

DR. D. S. DOUGHERTY said that, as a result of a statistical inquiry that he had been conducting, he had been astonished at the very large proportion of croupy children who are troubled with adenoids of the pharynx. To show the necessity for a thorough search for the cause, reference was made to an obstinate case of spasmodic laryngitis that had been the rounds without relief; after thorough cocainization and patient examination he had discovered a small medal wedged in between the arytenoids and the epiglottis; the removal of this foreign body cured the child.

DR. M. E. VARNEY, Saratoga Springs, said he wished to add his personal testimony to that of Dr. Way regarding the efficacy of nitroglycerin in spasmodic laryngitis.

DR. H. W. BERG spoke in favor of treating cases of laryngismus stridulus with bromids just as one would do in a case of epilepsy.

Report of the Committee on Vaccination.

DR. FREDERICK W. LOUGHRAN presented the report of the committee on vaccination. Although the work of the committee thus far had been tentative, and the Association took no definite action upon the report at this time, certain suggestions and recommendations were embodied in the report. The more important of these were the following: 1. All boards of health in cities and towns should furnish the means for vaccination and revaccination. 2. The state should have authority to enforce vaccination during the prevalence of smallpox. 3. No child should be admitted to school who had not been vaccinated within five years successfully, or who could not produce a certificate from a reputable physician, stating that vaccination had been twice performed, and that vaccinal insusceptibility exists. 4. The inmates of state asylums and members of the National Guard should be required to be vaccinated. 5. All corporations or firms having in their employ ten or more persons should be required to see that all such employes have been properly vaccinated, or are provided with a certificate as already mentioned. 6. The penalty for the violation of such vaccination laws should be a fine of $50 to $100, or an equivalent term of imprisonment, this penalty not to stand in lieu of vaccination.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fourteenth Annual Meeting, held in Richmond, Va., Nov. 12, 13, 14, 1901.

(Concluded from p. 1482.)

President Dr. Manning Simons, Charleston, S. C., in the Chair.

THIRD DAY—MORNING SESSION.

Foreign Bodies in the Esophagus.

DR. JOHN W. LONG, Salisbury, N. C., stated that this accident occurred usually in children and lunatics. It is always possible when a patient is under an anesthetic, and even food may become impacted in the esophagus. The presence of a stricture, pouch, or malformation increases the liability to this accident. A foreign body in the esophagus carries with it both immediate and remote dangers. If lodged high up, there will be dysphagia, retching, and sometimes suffocation, as in a case seen by the writer two years ago, in which an inch screw entered, point downward, the upper end of the esophagus of a 3-month infant, and impinged upon the trachea. When the foreign body is lodged lower down, the danger is more remote and less easily remedied. Unless removed, foreign bodies almost invariably penetrate or ulcerate into some important viscus, as the pericardium, aorta, mediastinum, the pleura.

Gunshot Wound of the Abdomen.

Dr. John C. Wysor, Clifton Forge, Va., reported a case of gunshot wound of the abdomen; the 38-caliber ball entered about three-quarters of an inch above the left anterior superior spine of the ileum. Patient was anesthetized fifteen hours after the receipt of the wound, having been transported a long distance. The author first enlarged the wound in the skin, and with his finger as a probe followed the track of the bullet until he felt the opening in the peritoneum. He then made an incision in the median line below the umbilicus which was afterwards extended from a little above the navel to near the pubes. The omentum was very short, not reaching as low as the umbilicus, and the coils of intestines presented immediately under the incision. The first knuckle picked up showed two perforations, which were immediately cleansed and closed with Lembert sutures, using fine chromicized catgut and he continued to close the openings as he came to them, until he had sewed up nine perforations. Following the gut still further, he found a portion seven or eight inches in length in which there were six more perforations. As some of these openings were very close together, he feared that in repairing them he might constrict the gut, or that there might be subsequent sloughing. He therefore excised that portion of the intestine, doing an end-to-end anastomosis by means of a Murphy button. Recovery was uninterrupted.

Penetrating Wounds of the Abdomen.

Dr. E. D. Fenner, New Orleans, gave in detail the histories of six laparotomies for penetrating wounds of the abdomen and statistical tables of 152 cases operated on at the Charity Hospital.

Nephro-Ureterectomy.

Dr. J. Wesley Bovee, Washington, D. C., detailed a report of two cases. The first one was a nephrotomy followed by incomplete nephro-ureterectomy for pyonephrosis, adrenal tumor and pyo-ureter; extraperitoneal operation; recovery. The second case was nephrotomy followed by complete nephro-ureterectomy for pyonephrosis and pyo-ureter; extraperitoneal operation; recovery. After narrating these two cases the author dwelt upon the indications for nephro-ureterectomy, saying that the principal reason for this operation is tubercular disease of both these structures.

Dr. George H. Noble, Atlanta, read a paper in which he spoke of and advocated the use of adhesive straps for the prevention of laceration of the perineum in forceps delivery. He also described a method of removal of fibroid tumors through the vagina by continued spiral incision.

Report of Case of Hepatotomy for Biliary Obstruction.

Dr. W. E. B. Davis, Birmingham, Ala., read this paper. The case was the fourth in which he had performed this operation, the first having been done in October, 1898. The operation is indicated in cases of obstruction with enlarged liver, where the gall-bladder or ducts can not be isolated, or the patient's condition from exhaustion and cholemia will not permit of a protracted search for the bladder or ducts, and is intended to bridge the patient over for a radical operation. It will be only exceptionally called for, but is the only available procedure in such cases. The bile will escape from an incision in the liver as it does in a cholecystostomy, and after the patient's condition has improved, the stone may be removed from the duct. The operation will be less frequently called for, as the surgeon's experience increases in choledochus operations, as he will then be better able to locate the bladder and ducts so much changed. The operation should also be resorted to in hepatitis before it has reached the stage of pus formation, if the liver does not rapidly become smaller after drainage of the gall bladder or ducts.

Third Day—Afternoon Session.

Dr. Joseph Taber Johnson, Washington, D. C., detailed two interesting cases in which attempts were made to produce abortion. In one case a medical man attempted to produce abortion at about the tenth week of gestation by inserting into the uterus a No. 8 flexible bougie. Some difficulty was experienced in getting it to pass the internal os, but after persistent effort the instrument was pushed up nearly its entire length, leaving perhaps two inches protruding into the vagina. The bougie was supposed to be coiled up in the uterus. Its expulsion was prevented by a cotton tampon pushed high up in the vagina. A physician informed the writer that when he removed the tampon the fetus and a portion of the membranes came away. He was unable, however, with the most diligent search to find the bougie, and finally came to the conclusion that it must have slipped out without the patient's knowledge, during one of her many visits to the closet in the night. The second day after the abortion, the patient had a severe chill, followed by a considerable acceleration of pulse and temperature, with gradual but steady increase of abdominal pain and distension. Dr. Johnson saw the patient in consultation, made an abdominal section, and removed the bougie from the peritoneal cavity.

The second case was one of ruptured umbilical hernia, in which several feet of intestine had been out on the surface of the abdomen and covered with unsterilized cloths and bandages for at least seventeen hours. The patient had had the hernia for fifteen years, and was 57 years of age. The intestines were very dark and very cold and dirty. A thorough cleansing and warming with hot salt solution succeeded finally in getting them and the adjoining skin of the abdominal wound into a tolerably fair condition. About a pound of omentum was removed, which bled in a number of places, from which adherent clots had been detached. The tight rim encircling the protruding gut was incised above and below, and the three feet of intestine returned to the abdominal cavity, which was subsequently filled with hot salt solution. A rather long and difficult operation was then performed for the radical cure of an old umbilical hernia in a very fat abdominal wall. The woman gave every promise of getting well for seven days, then she suddenly grew weak, and collapsed and died on the eighth day apparently of a general septic peritonitis.

Dr. Southgate Leigh, Norfolk, Va., reported a case in which he did a plastic operation for loss of base of the bladder. He also narrated a case of ovarian cyst in a negro woman which was complicated by a fibroid tumor of the uterus.

Hernia of the Ovary.

Dr. William P. Matthews, Richmond, Va., reported this case. The patient, Miss E., aged 17, 5 feet, 6 inches high, weight 145 pounds, strong and robust, was born with a swelling in each inguinal region which did not occasion any alarm or produce any inconvenience until she reached her 14th year, when they began to enlarge and at intervals became so tender as to confine her to bed for two or three days. Pressure on them produced pain and nausea. She never menstruated. The author operated for the relief of the hernia, following the Bassini method. The sac was firmly adherent to the internal ring and to the adjacent part of the canal. The sac was opened and a tumor enclosed in several layers of fascia was exposed, carefully dissected out and examined. It proved to be an adenoma of the ovary, though it looked more like a testicle than an ovary. The specimen consisted of four distinct parts: 1. An oval flattened body, 6 cm. long, 3 wide, and 1.3 thick. 2. A cystic tube, 5.2 cm. long, one end of which was dilated. This was joined in part to the body by fibrous connective tissue. 3. Parallel and beneath was another tube which entered the body. 4. Perpendicular to this latter tube was a third tube which also entered the body. Upon section the body showed a grayish-red surface, with one white well-isolated tumor. The microscopic examination was made by Dr. G. Baughman, which accompanied the paper. Examination revealed absence of the uterus. The ovary was removed and the parts closed in the usual manner, and the patient left the hospital in three weeks.

Inquiry into her family history revealed interesting facts. Her great-grandmother was an only daughter. She was twice married, and bore children in each union. Of the female descendants of the first marriage there were eight that were

never unwell in their lives, and all lived to be over 20 years old. Of the second marriage there was one of the two daughters who was never unwell. Two aunts of the patient have never menstruated, and one has a double reducible inguinal hernia. Five first cousins of the patient have never menstruated, and two of these are ruptured just as she was. One sister of the patient has never menstruated, and has a reducible hernia in the left side, an irreducible on the right. One fact he learned is that these women who have never menstruated have hardly any hair in the axilla and on the pubes and are not troubled by any unpleasant odor from the perspiration.

DR. GEORGE S. BROWN, Birmingham, Ala., read a paper in which he described a modified Hodgen's splint for the treatment of fractures of the thigh. He also demonstrated the application of this splint on a negro.

DR. CHARLES P. NOBLE, Philadelphia, read a paper on "The Treatment of Procidentia Uteri."

The following officers were elected for the ensuing year: President, Dr. W. E. B. Davis, Birmingham, Ala.; first vice-president, Dr. J. Wesley Bovée, Washington, D. C.; second vice-president, Dr. John W. Long, Salisbury, N. C.; secretary, Dr. W. D. Haggard, Jr., Nashville, Tenn.; treasurer, Dr. F. W. McRae, Atlanta, Ga.

Cincinnati, Ohio, was selected as the place for holding the next annual meeting, the second Tuesday in November, 1902. Dr. Thaddeus A. Reamy was selected as the Chairman of the Committee of Arrangements.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

PRESCRIPTION WRITING, IV.

(Continued from p. 1486.)

NECESSITY OF CARE.

The necessity of avoiding ambiguity has already been dwelt on to some extent. Every prescription, however, should be carefully read by the writer in order that due care may be taken to avoid omissions or mistakes in the size of the dose given and to review carefully the directions to the patient. The young physician experiences no little difficulty in calculating properly and quickly the doses of each ingredient if he writes a compound prescription, and especially is the difficulty increased if he desires to express the amounts in the form of the metric system.

In calculating the size of the dose many things must be taken into consideration which include some of the following important points:

1. The age of the patient.
2. The form of administration, if given by the mouth.
3. The frequency of administration.
4. The idiosyncrasy of the patient.
5. The action of each ingredient individually and combined.
6. Whether the ingredients are fugitive or cumulative in action.
7. The methods of administration.
8. The avoidance of incompatibility.

AGE OF THE PATIENT.

Narcotics and opiates should be administered to children with great care. There can be no doubt that opiates are prescribed a great many times in treating the summer diseases of children where other and milder preparations would be of far greater service. While children and infants are very susceptible to the action of opiates, on the other hand they can withstand the effects of cathartics in much larger doses, comparatively speaking, than can adults. For instance, infants only a few months old may be given the mild chlorid of mercury in doses of gr. 1/10 (.006) to gr. 1/6 (.01) every hour until several doses are given if necessary, which is practically equal to the dose given an adult. In prescribing for the aged, however, extreme care must be observed in the administration of cathartics. Cases have been reported in which cerebral hemorrhage and consequent hemiplegia have resulted from prescribing too large doses of active cathartics. Such results are to be expected when arteriosclerosis is present in a marked degree and when the cerebral arteries, lacking the proper resiliency, give way to the undue pressure produced by the overstraining at stool as a consequence of the purging.

ADMINISTRATION PER OS.

In speaking of the second point, the age also of the patient must be borne in mind. Children can not swallow a capsule, and it is with difficulty that they can be induced to take medicines which are unpleasant to the taste. Therefore, in prescribing liquid preparations for children a palatable vehicle should be prescribed, and when prescribing it in the powder form the same observance as to palatability must be carried out. For illustration, instead of prescribing quinin sulphate for children, some other preparation of quinin devoid of this objectionable taste should be used, such as the tannate of quinin, which will be readily taken by the patient. Euquinin is also a tasteless preparation. It is not uncommon to have requests from adults not to give them medicine in capsule form owing to their inability to swallow the capsule.

(To be continued.)

Treatment of Scarlatina in Its Graver Forms.

M. Arviragnet, in *Presse Médicale*, recommends hydrotherapy rather than antithermic remedies for the reduction of temperature. The temperature of the bath may range from 64 to 68 F. for adults, and 77 F. for children. In the latter case, if applications are to be long continued, cold packs are better borne. In the cardio-bulbar forms, with irregular heart action and respiration, and a tendency to syncope, the best results are obtained by injections of caffein from grs. iii (.2) to grs. vii (.45), or spartein sulphate grain 1/2 (.3), or strychnin sulphate gr. 1/60 (.001). In the hemorrhagic forms, in addition to the preceding measures, ergotin, iron, rhatany and hamamelis are advised. The following combinations are sometimes administered:

℞. Acidi gallici	gr. xv	1
Syr. aurantii	ʒi	32
Aq. destil	ʒii	64

M. Sig.: One teaspoonful every hour or two.

M. H. Roger, as noted in *N. Y. Med. Journ.*, obtains good results from the employment of calcium chlorid in hemorrhagic scarlatina:

℞. Calcii chloridi (crys.)	ʒi-ʒiss	4-6
Tinct. cinnamomi	ʒi	4
Spts. vini gal.	ʒi	32
Syr. aurantii	ʒx	40
Aq. destil q. s. ad	ʒiv	128

M. Sig.: The above to be taken in divided doses in twenty-four hours.

To Control Hemorrhage.

The following combination has been employed to check hemorrhage from any cause:

℞. Tinct. hydrastis		
Tinct. viburni, āā	ʒiii	12
Tinct. hamamelidis		
Tinct. castaneæ (chestnut), āā	ʒvi	24

M. Sig.: Take 15 to 20 drops before each meal in sweetened water.

Treatment of Dental Caries.

The following is recommended by *Jour. des Pract.* as a disinfectant in treatment of dental caries:

℞. Formaldehyd	ʒv	20
Spts. geranii	ʒiiss	10
Alcoholis (80 per cent.)	ʒv	20

M. Sig.: Apply locally.

Treatment of Influenza (La Grippe).

The following are Huchard's formulæ to be employed in treatment of la grippe:

℞. Quininæ sulphatis.
Extracti cinchonæ, āā.....3ss 2
Extracti aconiti rad.....gr. iss |09
M. Et divide in pil. No. xx. Sig.: One, three times a day.

When pulmonary catarrh and inflammation is present in such cases, he prescribes the following:

℞. Pulv. ipecacuanhæ comp.....3ss 2
Pulv. scillæ.....3ss 2
Quininæ sulph.....3ss 2
M. Et divide in pulv. No. xx. Sig.: Four or five daily.

For the gastric pain and vomiting the following:

℞. Sodii bicarb.
Mag. calcinatæ.
Bismuthi salicylatis, āā.....gr. v |30
Misce et fiat chartula No. i. Sig.: One such powder every four or five hours.

Agalactia (Deficiency of Milk).

℞. Tinct. nucis vom.....3iv 16
Calcii glycerophosphati .....gr. xv 1
Elix. calisayæ .....ʒiv 128
M. Sig.: One tablespoonful three or four times a day in water.

Treatment of the Convalescent Stage of Diphtheria.

Yeo states that there can be no doubt as to the value of strychnia as a cardiac tonic. He recommends it in the following prescription form:

℞. Ferri et quin. citratis .....gr. lxxx 5|30
Liquoris strychinæ.....3ss 2
Acidi hydrochlor. dil.....m. lxxx 5|30
Aq. chloroformi q. s. ad.....ʒviii 192
M. Sig.: Take two or three tablespoonfuls twice or three times a day an hour after meals.

For children the following is advised:

℞. Syr. ferri phosphatis.....ʒi 32
Calcii hypophos .....gr. xlviii 3|20
Quininæ sulphatis .....gr. xxiv 1|66
Liquoris strychninæ .....m. xlviii 3|20
Acidi phosphorici dil .....m. xxiv 1|66
Aquæ q. s. ad.....ʒiv 128
Misce, fiat mistura. Sig.: One or two teaspoonfuls, according to age twice or three times daily.

As a disinfecting mouth wash the following:

℞. Pot. chloratis pulv. 3ii 8
Glycerini boracis .....ʒi 32
Acidi borici 3ii 8
Glycerini acidi carbol.....ʒi 32
Aq. menth, pip. q. s. ad.....ʒxii 384
Misce, fiat gargarisma. Sig.: To be taken and mixed with equal quantity of hot water and used.

Prevention of Abortion.

Horrocks, as noted in *Med. Record*, recommends the following precautions for the prevention of abortion: Avoid overstrain, shock and fright. Operations should not be performed if they can be avoided; especially should the extraction of teeth be avoided. Avoid using instruments about the uterus and cervix, and too hot douching. Pessaries should not be worn after the fourth month. Purging should not be resorted to nor should enemata with turpentine or glycerin be used. Cessation from coitus aids gestation to progress to full term. Uterine displacements should be remedied if possible and tight lacing prohibited.

Drugs which have any tendency to ecbolic action should not be administered to a pregnant woman. The following drugs are included in this list: Ergot, savin, digitalis, quinin, lead. We might add that large doses of aloes by producing a congestion of the female organs of generation may be considered in the above list. Syphilis if present should be treated in the parents and very often small doses of mercury may be advantageously given throughout pregnancy. Overnursing must be avoided. The administration of alcohol should be carefully guarded and in most cases avoided altogether. High pyrexia from any cause must be reduced and controlled by cold baths.

Medicolegal.

Crime Against Nature—Evidence.—The Supreme Court of Illinois holds, in Kelly vs. People, that the statutory provision that "the infamous crime against nature, either with man or beast, shall subject the offender to be punished by imprisonment in the penitentiary for a term not more than ten years," covers the offense committed by the mouth, although the common-law crime against nature does not. Nor does it seem to think that any distinction is to be drawn between cases in which the accused is charged with using his mouth upon another, and in which he uses the mouth of another upon himself. Furthermore, the court, while not unmindful of the fact that the crime is of a class easily charged and difficult to disprove, and that it should therefore be established with clearness, sustains a conviction in this case upon the uncorroborated testimony of a boy between 6 and 7 years of age. Consent on the part of the boy, it says, could not be presumed, he being incapable of understanding the nature of the act. He was incapable of committing a crime.

Admissible Evidence of Physician in Injury Case.—The Supreme Court of Illinois says, in City of Salem vs. Webster, a personal injury case brought by the latter party, that objections were made to the testimony of physicians as to what the party suing said to them while being examined and treated in describing his feelings and detailing the nature and location of his pains and sufferings. But it holds that the evidence was admissible, because as to such matters the opinions of the physicians must necessarily be formed and guided by statements of the patient. Moreover, one of these physicians was near by when the accident in question happened, and, with another person, picked the injured man up, and carried him to his house. He was allowed to state that the man at that time cried out with pain, and described the pain in his back. What was stated, the court goes on to say, was not a recital of any past event, but the natural expressions of suffering. The physician took the man right into his own house, close by, and immediately administered to him as a physician. The physician heard the accident, and was at the spot almost immediately, and was guided by the groans of the man to the place where he lay. The evidence, the court holds, was admissible as the natural expressions of suffering, if not as a part of the res gestæ, or essential circumstances of the case.

Physician's Opinion Evidence of Permanent Injury.—Supreme Court of Illinois says, in Donk Bros. Coal & Coke Company vs. Peton, that the physician who treated the latter party after he was injured testified that he found a fracture of both bones of the leg, one at the ankle-joint and one about two inches above the ankle-joint; that the smaller bone was broken right at the ankle-joint, and that the man would "never have a permanent ankle-joint." Notwithstanding this, it was contended that there was no evidence of a permanent injury on which an instruction could be based that if the jury found from the evidence that the man's injuries were permanent, they might take that fact into consideration, and award him such damages as, from the evidence, they might believe was just and right, and such as would compensate him for his injuries. The Supreme court, however, does not agree with the contention, but holds that if, in the opinion of the physician as thus testified to, the man would never after the injury have a perfect ankle-joint, the court could not say that there was no evidence of a permanent injury, and that, therefore, the instruction was not erroneous on the ground contended.

Things Patient May Rely on—Conflicting Evidence.—In the case of Schoonover vs. Holden, which was brought to recover for the alleged negligent treatment of a lateral dislocation of the knee-joint, the attention of the Supreme Court of Iowa was called to the following instruction asked in behalf of the physician sued: "It is the duty of the party injured

to use all reasonable efforts on their part, so far as possible, to prevent damages from resulting therefrom. And, if they do not do so, they can not recover for such damages or injury as they might have thus prevented. Upon this branch of the case you [the jury] are instructed that you may take into consideration the knowledge, if any, the plaintiff has shown to have had of the injury complained of; her knowledge, if any, as to the condition of her limb after the defendant had told her that it was reduced, and whether or not she made any efforts to determine whether her conclusions were correct, and, if she did, whether or not she acted upon the knowledge she had thus obtained, by calling other physicians, and having the dislocation complained of in the case reduced." But this instruction, the Supreme court holds, was properly refused, because it required the patient to determine whether the physician attending her was giving her injury necessary treatment. She had the right to rely upon his professions of skill as a physician, without calling others in to determine whether he really possessed it or not, and she was not bound to call other physicians unless she was fully aware that he had not been and was not properly treating her injury. Besides, the court makes the point that the physician himself said that his treatment was the usual treatment in such cases, and that the evidence conclusively showed that the patient was assured by him that he had reduced the dislocation, and that she was receiving approved treatment. There being a conflict in the evidence on all material questions affecting the right to recover damages, including the want of care on the part of the patient, the court says that, under the well-established rule in such cases, it can not disturb the verdict rendered in favor of the party suing, and so it affirms a judgment thereon against the physician sued.

Specialist Allowed His Bill for "First" Treatment.—In the case of Williams vs. the Griffin Wheel Company, an action brought by a physican and surgeon against a corporation, for services rendered as an eye specialist to an employe of the company who had been injured while at work for it, the Supreme Court of Minnesota affirms an order denying the company a new trial after judgment was obtained against it. The physician suing did not receive instructions or authority to render the services directly from the company, but through another physician, who was authorized to employ a specialist on this particular occasion for "first" or primary treatment. The company declined to pay the bill on the ground that the value of services other than those authorized—that is, further or subsequent services—was included. The case was tried by a jury, and the court is of the opinion that there was evidence which warranted a finding that the services for which compensation was claimed were, under the peculiar circumstances of the case, first or primary, and that no part thereof could be called further or subsequent services, although the testimony as to what could properly be designated first or primary services in such a case—a very severe injury to the eye—was very meager, and was all given by the physician suing. Objection having been made to his being asked a question which called for his opinion or conclusion as to the party for whom and on whose faith and credit he rendered the services, the court holds that the objection should have been sustained. It says that his opinion or belief that the faith and credit of the corporation were pledged for the payment of his bill, and that it was responsible for the same, was not proof that the liability existed. The conclusion that it did was to be deduced from what transpired between the parties and upon the facts as to the employment, not what he thought or believed. But the testimony as to the company's liability for first or primary services subsequently becoming practically conclusive, the court holds that the overruling of the objection was error without prejudice. The court adds that there was no testimony that the first or primary services in this case did not exceed $15 or $20 in value, as argued by counsel; that the other physician referred to, who testified that he was not qualified to say what "first" services were in such a case, went no further than to testify as to the value of the services performed the first day by the physician suing.

1. **Albumin in the Urine.**—Osler shows that a minute quantity of albumin in the urine with a few casts is not necessarily a matter of serious import. They are danger signals which may be of use in guiding the patient to better methods of living and, therefore, their occurrence indirectly serves to prolong his life. The points on which one should lay special stress as indicative of serious disease are: 1. Persistent low specific gravity of the urine, 1008 to 1012. 2. The condition of the heart and arteries—marked sclerosis of the peripheral arteries, with the apex-beat of the heart an inch or two outside the nipple line, and a ringing and a highly accentuated aortic second sound. 3. The presence of albuminuric retinitis. A trace of albumin and a few tube casts are simply warning to the engineer to go slow, for the pace is too rapid for the state of the track.

3. **Vesical Emergencies.**—The methods of meeting conditions of urinary retention are especially noted by Fuller, who advises as regards the use of the catheter, the filiform bougie, etc. A soft rubber catheter can never produce harmful trauma, but the hard metal instruments can do so and are never recommended for constant use by any progressive physician. Where prostatic obstruction is so great as to require this instrument, a prompt resort to radical surgery should be insisted on. As regards the perineal incision, which is usually chosen, he warns against the too short incision and gives the details of the methods of managing cases of retention due to stricture complicated by extravasation and perineal gangrene, which have already been published by him in his work. Where prostatic obstruction occurs in cases not amenable to catheterization, prostatectomy should be immediately performed.

4. **The Boston Ice Supply.**—This article gives a review of the various sources of the ice supply of the city of Boston, including artificial ice, and their bacteriologic and other possibilities. Hill sums up by saying that, on theoretical grounds, the danger of infection through ice, either natural or artificial, is almost *nil*. There is but one presumably authentic case on record of transmission of typhoid fever through ice. In this country but one case has been attributed to ice, and in this the evidence was indefinite. Snow ice apparently contains a large number of bacteria, but clear ice is much less contaminated. Artificial ice may contain near its center or bottom about as many bacteria as the average natural ice, but the bacteria present, excepting in very rare instances, are practically harmless. Dirt is found in both natural and artificial ice, usually more abundant in the former.

8. **Wounds of the Bladder.**—The accident of wounding the bladder is rare. Cumston has had but one case in 300 abdominal sections and one out of 74 cases of vaginal hysterectomy. The cases are reported and in neither was the result bad. The anatomy of the parts is carefully described, and the abnormalities, especially displacements, compressions, etc., of the bladder by tumors are detailed. The technique of the treatment of the bladder injury is given according to the various authorities. The author's method is as follows: Two layers of sutures are employed, the first of which includes the mucous membrane alone; for this fine catgut should be used. The second and superficial layer of sutures includes the muscle. If the bladder is deeply seated, and if the abdominal walls are very thick, the mucous membrane may first be united by interrupted sutures of fine catgut, but if the wound in the bladder is easily accessible, a running suture is to be preferred. As to the superficial suture, it should always be done with a running Lembert's suture. In some cases, especially if the wound in the bladder is a long one, these two layers of sutures may be reinforced by a third layer of Lembert's suture. This method has two advantages: In the first place the mucous membrane is brought into better apposition and it is easy to understand that these two layers of suture would more completely occlude the opening than the technique recommended by Guyon and others. The drainage of the bladder can be accomplished by free urethral drainage or directly from the ureters, and he thinks that in cases of very large openings into the bladder made occasionally during operation, permanent catheterization of the ureters might possibly be of value. As ordinarily practiced permanent drainage of the bladder is usually employed, and he suggests care in choosing of the catheter, the precautions to be employed and the duration of the drainage. He would change every four or five hours in the female, but if we desire to use permanent catheterization the Pezzer instrument is about the best. When the permanent catheter is used and not changed, it usually becomes occluded by salts, and if the Pezzer sound has been used it is better to use the ordinary catheter after its removal rather than to reendeavor to introduce another instrument of the same description. He has found that after suture of the bladder following suprapubic cystotomy, five or six days' drainage is usually enough, but others have advised a longer period. If the sound should be left without removal for a week or ten days, it is better to use intravesical injections of 1 in 2000 solution of either lactic acid or phosphoric acid every other day to prevent the deposit of urinary salts. He thinks permanent drainage is necessary to prevent distension of the organ, and to allow solid union of the wound. If septic complications should occur, the abdomen should be opened, and thorough irrigation with saline solution and the permanent catheter should be carefully watched to see that the drainage is perfect.

9. **Nurses' Training Schools.**—Cabot suggests putting nurses' training schools on a sound basis, the students helping to pay the salaries of paid instructors. Nursing should be taught by nurses, medicine by physicians. The preparation for private nurses should be in private families and by private nurses. There should be a better balanced curriculum containing liberal as well as purely technical studies.

11. **Yellow Fever.**—An account of the experimental work with yellow fever by inoculations for immunization is given by Guiteras with details of cases, temperature charts, etc. The result was that the cases thus produced were not found to be invariably mild, as a history of the experiments has shown. The charts that are published give us facts in regard to the early stages of the disease which were not previously known, but Dr. Guiteras thinks the cases are the average ordinary yellow fever cases. While the object of the experiments was not to confirm the mosquito theory it nevertheless is useful for this end, as it shows that all forms of yellow fever from the mild to the severe, hemorrhagic, uremic, etc., can be produced, which is opposed to the belief that there must be some other means of communication. They also seem to show the exclusive rôle of the Stegomyia and the innocuousness of fomites.

13. **New Substance in Bone.**—The constituent discovered

by Gies—the osseomucoid—is apparently the same as the mucoid in tendon cartilages and other connective tissue. It shows that ordinary compact bone like other forms of connective tissue contains the mucin substance and also, contrary to Young's deduction, that in the process of ossification the connective tissue matrix is not completely removed. It also makes it easier to understand the accumulation of mucin in various pathologic forms in osseous tissue shown by numerous observers in recent years.

14. **Ovarian Pregnancy.**—The literature as regards ovarian pregnancy is discussed by Scott, who suggests the possibility of ovarian hematomas being thus produced. A case is reported with careful macroscopic and microscopic examination and he sums up as follows: Hematomas of the ovary are comparatively common, and we have no explanation for their occurrence. Ovarian pregnancy is a proven possibility. Continued development of the ovum in ovarian pregnancy causes changes in the organs and tissues such as to render the demonstration of its ovarian origin impossible. The most natural consequence of the early death of the ovum in ovarian pregnancy is its gradual transformation into an ovarian cystic tumor, added to this retrograde changes obscure its origin, and a hematoma is the final result.

16. **Annular Pancreas.**—Abnormalities in the anatomy of the pancreas are discussed by Tieken, who describes the varieties and reports a case. As regards the genesis of annular pancreas the following is suggested: If the ventral and dorsal diverticula did not unite as they normally do, but develop independently, there would be pancreatic tissue on either side of the intestine, and as growth proceeded the bowel soon would be completely surrounded by glandular tissue. In the semi-annular type, the condition might be due to an overdevelopment of the head, which sends out processes, partially surrounding the bowel; if this hypertrophy should continue until the processes meet on opposite sides of the duodenum, there would be a true annular pancreas, and there is no reason why this could not occur. Some of these malformations can not be detected during life and do not produce pathologic conditions of a serious nature. Accessory pancreas may be a factor in the production of deviations of the intestines or may become the seat of tumor formation, and the semi-annular type, according to Genersich, is of some practical importance on account of the possibility of its producing duodenal constriction. The annular pancreas, however, is capable of producing conditions which may become of great importance, as shown in the case reported here, where obstruction of the bowel was marked, and led to great dilatation of the duodenum. After the obstruction has become a little more pronounced it is easy to see the consequences that might result. If tumor should develop in the head of the pancreas, there will be early stenosis of the bowel and probably occlusion of the bile ducts as well, and this might lead to a suspicion of hour-glass contraction of the stomach. The accumulation and decomposition of food in the duodenal sacculation is another possibility which might produce serious results. Tieken concludes by saying that annular pancreas is of interest from a practical as well as from a pathologic standpoint, and should be taken into consideration in all obscure cases of tumors and obstruction at or near the pancreas.

17.—See abstract in The Journal of September 14, p. 711.

19. **Genuine Vaccinia.**—The characteristics of genuine vaccinia in its typical form are first given by Welch and Schamberg, who ask what constitutes successful revaccination. They think that in many cases it may be modified decidedly from the earlier form, but there are certain false vaccinia conditions which claim attention. The raspberry excrescence is one and is utterly devoid of protective power. The authors' experience with the glycerinated lymph has been favorable and they see no reason why it should not be relied on. It is possible that there may have been a difference of quality in the products from various sources giving reason for unfavorable results that have been reported by certain authors. The fault is mainly in the preparation of the glycerinated lymph. The whole lesion is curetted, bringing away lymph, vesical walls and broken-down tissue. He thinks the unpleasant results sometimes observed from the use of this form of vaccine matter may be due to the method by which it is obtained. In cases of infants, if there is no smallpox about, we can wait until the age of three months, but during an epidemic no age is a contra-indication to the performance of vaccination, nor are other diseases a contra-indication. If the child is successfully vaccinated in infancy and again at the age of puberty, the immunity will probably be permanent, though infection is common enough to warrant revaccination whenever smallpox is epidemic. The quality of the vaccine is far more important in their opinion than the quantity. Therefore, one good vaccination cicatrix should be as efficient as several.

21. **The Technique of Vaccination.**—Packard is also a believer in the glycerinated vaccine. He notices the importance of sterilization and prefers a scarificator for the reason that it would be likely to be used for this alone. He has been in the habit of using a point just below the head of the fibula when he does not vaccinate on the arm. The only thing that would make him vaccinate elsewhere would be varicose veins at his point of preference. The advantage of this location is that it is subject to less friction and, therefore, safer from contamination. He also favors the use of shields. The celluloid shield allows the patient to inspect his arm and derive more or less amusement therefrom, and also permits the radiation of heat and avoids the poulticing effect. He removes the shield as soon as a specific local lesion has been produced and has the arm dressed either with boracic acid or aristol, one dram to the ounce of ointment. In spite of all care, some arms will be sore and in cases where there is a surrounding edema or cellulitis he thinks the rational treatment is to surround the arm with an antiseptic pad of gauze soaked in 1 to 3000 bichlorid of mercury solution. Another point of great importance is proper judgment whether or not the vaccination has been successful.

23. **Blood Examinations.**—Deaver and Moore's experience covers the subject of parasites, serum, hemoglobin and blood count examinations. They find it sometimes difficult to detect the malarial parasite soon enough to get a prime diagnosis, especially in the irregular and atypical cases and a single negative examination can not be considered decisive. There is very little direct benefit derived from cultures taken from the blood in bacteremia, and in suspected malignant endocarditis the results have usually been negative. They are opposed to disturbing or painful examinations that do not promise positive benefit. The sources of error in the Widal reaction are noted and they call attention to the fact of its occurrence in tuberculosis and also for years after typhoid fever. The positive Widal is never of very much value to the surgeon, however it may be to the physican. They are not in a position to judge of the negative serum reaction in various infections such as tropical dysentery, colon, paracolon, proteus, etc. They are also skeptical as to gelatin and calcium chlorid in preventing hemorrhage. Sugar in the blood is more a matter of curiosity than of value. Justi's hemoglobin test for syphilis has proven very satisfactory in the cases where used. In doubtful cases it is well worth a trial. They do not consider any low percentage of hemoglobin a positive contra-indication to surgery in active suppurative conditions or after hemorrhages. The erythrocyte count, as an index of resistance, is of value and is as well a guide to the severity of the affection. Leucocytosis is both the most valuable and most disappointing part of the subject of these blood examinations. Their experience with the leucocyte count is given in a paper published in the *Philadelphia Medical Journal*, June 1, 1901, and they say that, though at times it is very valuable, it is often very disappointing. In conclusion, they object to the unfounded claims that have been made for the procedure, and deplore unfortunate results that may follow misapprehensions from such statements.

24. **Supraorbital Reflex.**—This reflex, which consists of a slight but distinct contraction of the orbicularis palpebrarum

when the supraorbital nerve or its branches is struck a slight blow, is noticed by Sailer, who thinks it is a true sensory motor reflex. It may in certain cases extend to other muscles at a considerable distance from the supraorbital nerve.

25. **Bottini Operation.**—In this continuation of Horwitz's article in this number, he claims that the value of the Bottini operation as a prophylactic measure is based on an experience of 14 patients on whom he operated between the ages of 49 and 61 when they were just beginning to suffer from the effects of prostatic obstruction. In each case the operation was successful and the effects have been permanent. A number of cases are reported showing the good results.

27. **Traumatic Stricture of the Esophagus.**—The treatment of this condition is discussed by Bunts, who calls attention to the value of its diagnosis and its frequency due to the drinking of lye by children. The prognosis depends on the extent of injury of the mucosa and the rapidity of contraction. Most cases pursue an unfavorable course. He has treated eight cases from this cause and has devised a set of double-bulbed olive-shaped bougies which have given him much satisfaction. The bougie has an upper bulb a size larger than that of the lower. This enables one to follow the advantage gained by the passage of the first by the immediate passage of one a size larger. He speaks of the necessity of great gentleness and care in the use of these bougies. On inserting it is best to have the patient sit upright, in a straight-backed chair, the head thrown back somewhat, in order to straighten the line of introduction of the bougie. Instead of passing it directly back in the median line, it is probably better to pass it into the pyriform sinus at the side of the larynx, which affords a funnel-like aperture that will allow the bougie to slide into the esophagus without encountering the bodies of the cervical vertebræ or the cricoid cartilage. Force should never be employed. The cases are reported in detail. He thinks the use of his method will, in many cases, render the performance of gastro-enterostomy and retrograde dilatation unnecessary even in the most serious cases.

28. **Diagnosis in Nervous Diseases.**—The value of a correct diagnosis in many of the nervous diseases as a guide in the conduct of the physician, avoidance of needless expense to the patient, etc., is noted by Diller. He reports instances of tabes and paresis where an early diagnosis saved much trouble. Many nervous diseases, moreover, are curable and an early diagnosis is of importance.

30. **Hygienic Legislation.**—Scheppegrell's article is a history of a contest between him and the local authorities in New Orleans and, as the result, the passage of an antispitting ordinance over the mayor's veto.

31. **Primary Hepatic Sarcoma.**—According to De Vecchi and Guerrini the cases of primary sarcoma of the liver reported are so numerous that probably many of them are wrongly diagnosed. After reviewing critically 45 cases they come to the conclusion that the majority of these should be excluded from the list of primary tumors, and the following is the statement of their results: Ten cases which are reported probably are not sarcoma; namely, the cases of Naunyn, Lancereaux, West, Roberts, Lee, Pepper, Koltmann, Tooth, Hall, White, Maisenbach and Henschen. The case of Naunyn probably is one of proliferation of Glisson's capsule; that of Lancereaux one of fibroma; West's case is very doubtful, and Roberts' probably a fungous hematode; the cases of Lee, Pepper, Koltmann and White are carcinomata; Tooth's case is a leucemic or a tubercular lesion, Maisenbach's a myxoma and Henschen's a cystic telangiectatic carcinoma. Seven other cases must probably be excluded also, namely, those of Frerichs, Wagner, Block, Ledue, Pellacani, Parker and Burnett, since sarcomatous nodules were found in other parts of the body, to-wit, in the skin, intestines, eyes, spinal cord, etc. Eight further cases (Warren, Warshawski, Hutyra, McKee, Axtell, Knoch, Krasnobajew) they have not been able to investigate thoroughly; probably some of these would also have to be excluded. They report two cases of primary sarcoma which came under their observation in which they considered the neoplastic tendency to be attributable to a preceding cirrhosis.

33. **Rabies.**—Salmon's paper is a discussion and convincing analysis of the statistics, combating the statements of Dulles and others who argue that hydrophobia does not exist.

34. **Typhoid Fever.**—Golden gives certain particular points derived from his experience with typhoid in West Virginia. The course is usually atypical, and constipation is more common than diarrhea. An unduly high temperature at the beginning is frequently seen. Relapses are exceedingly common under the best management. The mortality is small, not exceeding 6 per cent. He notices certain houses which in spite of re-adjustment of water supply, plumbing, etc., seemed to be infected with typhoid. He holds to the milk diet. In cases where he has varied from it or seen it varied, he thinks the results have been bad. In cases of well-nourished patients with high temperature, he would keep them down even to a pint of milk a day with plenty of water and very small doses of alcohol frequently administered. Abortive cases he has learned to disbelieve in. Tympanites is usually controlled by diet, but an enema of saponified water, holding in emulsion 1 dram of oil of turpentine, will usually control it and he makes this a routine treatment. Of internal antiseptics he has faith in thymol, but the Woodbridge treatment is generally condemned in his section.

35. **Rupture of the Urethra.**—After reporting three cases, Hayden says that treatment is operative or non-operative according to the nature and extent of injury which, as a rule, can be readily ascertained by a careful study of local conditions: If there is marked hemorrhage from the meatus with a complete retention of urine, or difficult and painful urination and bloody urine, associated with difficulty or inability to enter the bladder with instruments; and, also, if there is a fluctuating perineal tumor, with perhaps a rise of temperature, then immediate perineal section and bladder drainage are indicated. If, on the other hand, hemorrhage is slight, urination free, but somewhat painful, the urine tinged with blood, or containing light bloody flakes, and catheterization normal, except perhaps causing some pain at a localized spot, which feels slightly roughened or thickened, and little or no perineal tumefaction, then catheterization, irrigation, and urinary antiseptics should be resorted to, the patient in the meantime being kept in bed, and carefully watched for the first sign of urinary extravasation, in the event of which external urethrotomy with vesical drainage should be immediately resorted to. Partial suture of the urethra must always be employed in case of complete rupture, in which the divided ends of the canal are widely separated; otherwise it is not essential. Complete suture of the damaged canal is, in the writer's opinion, contra-indicated, as it prohibits the free bladder and urethral drainage, which is so essential for the contused and infiltrated condition of the tissues in these cases.

37. **Value of the Widal Reaction.**—The following are the conclusions of Gershel's article: 1. The main facts concerning the Widal reaction in children are the same as those that hold true for adults. 2. In 84 cases of typhoid fever in children, ranging from one and a half to fourteen years of age, 81 cases gave a positive result. 3. In 115 cases that were fevers other than typhoid, the positive reaction was never obtained. 4. The reaction did not occur later in children than in adults, as is claimed by some writers, but on the other hand, somewhat earlier. However, too much stress on this point should not be laid. 5. The Widal test is of greater importance in children than in adults, owing to the frequent atypical character of the disease in the former, and the greater frequency of cases resembling pneumonia and meningitis. 6. As pointed out by Morse, the reaction will be of service in establishing the frequency of typhoid fever in children.

43. **Uterine Anomalies.**—The anomalies of the uterus bicornis, uterus didelphys bipartitus, etc., with their consequences and possibilities are described by Ricketts, who reports a case of double uterus and one of uterus rudimentarius

bicornis of his own observation. He gives in conclusion an extensive bibliography of the subject.

44. **Ignored Syphilis.**—Heidingsfeld reports his observations on this point in 21 cases out of 134 in which the patients denied any previous infection whatever. He thinks that in many cases it was due to the negative character of the history; patients are sometimes very slow in making admissions. In other cases the disease must have been recognized and there are still other cases where there had been a faulty diagnosis made. He insists on the importance of thorough diagnosis in every case and in the distrust of negative history in some instances. In many of the cases, too, there is extra-genital infection which also plays a part in the causation.

46. **Medical Education.**—This address by Gildersleeve reviews the subject of medical education, medical ethics, corporation practice, organization of the profession, reciprocity between the states, etc.

47. **Delusions in Medicine.**—Dickinson's article is an interesting review of the various medical superstitions that have existed, from early fetichism and enchantments down to christian science and osteopathy. He does not believe in the materialistic tendencies of modern medicine as the cause of the present growth of these delusions, but rather that they are proof of medical advancement. These frauds take up cast-off ideas and distort them. When public faith is lost in them they will have to revolutionize their systems to meet the changed conditions.

48. **Cancer.**—McGuire reviews cancer, its causation, pathology, etc., as to the various theories of the same, and holds that there is very little possible good in any treatment except by early and correct diagnosis and thorough operative measures.

58. **The Recidivist Criminal.**—The questions of heredity, environment, etc., of the criminal are discussed by Morel, who says in conclusion: "1. For the benefit of public health, the government should care for the young degenerates and take them away from the evil influence of their parents. 2. When these degenerates attract attention by their acts or conduct, they should be investigated and reported on officially, as well as professionally. 3. As far as possible, they should be placed in medico-pedagogic institutes directed by competent authorities. 4. Parents should have the privilege of placing in medico-pedagogic institutes children whose low intellects require special care; the children should be cared for up to the age of 18 years. 5. The question of vengeance should give way to that of ameliorating the condition of the offenders. The degenerate can not be held responsible, but should be cared for by society."

59. **The Regicides.**—Regis goes over the history of numerous assassins of prominent individuals, whom he divides into two categories: 1. Those suffering from a special form of insanity haunted by the idea that they have suffered a special injury for which they seek reparation. 2. Those who make attempts on persons under the influence of some variety of insanity are not cognizant as to their acts. Among the first of these he includes Mariotti, who attempted to assassinate Freycinet; Perrin, who fired a blank cartridge in front of President Carnot's carriage, and others. The true regicides may attempt to kill through religious or political fanaticism and are, in his opinion, always of a mystic temperament misguided by religious or political delusions, think themselves called on to act the part of judge and martyr and kill some great person in the name of God, the country, liberty, or anarchy. The fact that the individuals who survive end in becoming insane is, he thinks, in favor of his view. He believes that they should not be treated as responsible individuals or executed as such.

66. **Diabetic Coma.**—The case reported is offered because of the extreme grade of acidosis; because di-acetic acid was apparently absent for several months before death; because of the various facts which developed in the examination of the urine, stools, vomitus, and contents of the gastro-intestinal tract, relating chiefly to the absorption of sodium bicarbonate, the estimation of urea, the increasing percentage of ammonia, to the total nitrogen excreted, the unusual amount of acetone as compared with B-oxybutyric acid, the diminution of chlorin in the urine and its presence in the feces, and the excessive excretion of potassium. The patient, a boy of 15, improved very remarkably under dietetic diet and the administration of sodium bicarbonate, but died suddenly of a complication possibly due to an irregularity in diet, though its nature is not exactly stated. The case is analyzed with great care and the author thinks it furnished more than the usual amount of evidence to the already accumulated facts showing that diabetic coma is the result of acid intoxication.

67. **Glanders.**—Strauss' method of diagnosis of glanders consists in injecting the suspected bacilli into the abdominal cavity of guinea-pigs, where it produces peculiar suppurative results in the scrotal peritoneum. It has been experimented on by Frothingham, who considers it the most valuable test at our command. The positive test means everything; the negative test nothing, though several negative tests are of great value. He thinks the best results can be obtained when three or four guinea-pigs are used for each test, each pig receiving an injection of from .5 to 1 c.c. of the suspension, a small portion of which usually remains in the subcutaneous tissue, the rest being left in the peritoneal cavity.

71. **Diabetes and Degeneration of the Islands of Langerhans.**—Nine cases of diabetes are reported, in two of which there were marked pathologic changes in the islands of Langerhans which Wright and Joslin consider to be strongly in favor of the hypothesis that lesions of these structures are important factors in the pathology of the disease. Whether marked lesions of the islands of Langerhans will be found to be always associated with glycosuria, as Opie seems to hold, must be determined by further observations.

76. **Separate Localization.**—Mills reiterates his former view of the separate localization in the cortex and subcortex of the movements and of muscular and cutaneous sensibility, not admitting that the Rolandic and adjacent regions are sensori-motor as had been held by Munk, Hitzig, Bastian, Starr, and others. He reviews the evidences as to their functions and states that a separate and extensive sensory zone exists, which includes the gyrus fornicatus, precuneus, and postparietal convolutions, possibly also the hippocampal convolution as held by Ferrier. His arguments are given in detail and he thinks an analysis of the cases which seem to contra-indicate his view will show the incorrectness of the deductions from them. Owing to the fact that motor and sensory regions are co-terminous and frequently overlap, every case should be excluded in which the lesion described extends even for the fragment of an inch outside the particular motor or sensory region specially involved.

78. **Stadia of Mental Disease.**—Kellogg recognizes four stadia in mental disease: the incubatory period; that of active mental disturbance; that of reactive exhaustion, and the convalescent period, all except the third lasting on an average for a number of months. He sums up his paper as follows: "The vast majority of attacks of mental disease have but four simple stadia. The main stadium acutum is constituted chiefly of the maniacal, melancholic, or stuporous states, which are mere symptom-complexes alternating or replacing one another, though sometimes mistaken for separate attacks of insanity. Mental disease must be regarded as one continuous pathologic process with periodic fluctuations, so constant that remissions and intermissions are to be viewed as part of the morbid phenomena. The diversified curricula of insanity and the artificial variety of its forms described by modern writers may in great measure be reduced to clinical simplicity by the law of the stadia, conjoined with the maniacal, melancholic and stuporous states, as here rightly assigned to the position of symptomatic syndromes, rather than independent forms of alienation. In fine and in fact the law of stadium and rhythm and of the dominant states of expansion, depression and stupor are the only stable data

capable of any wide purpose for the logical unifaction of the multiform manifestations of mental disease."

83. **Rheumatism.**—The various drugs that have been tried as specifics for rheumatism—the salicylates, salophen and aspirin—are noticed by Coverley, who finds that the latter is in his opinion the most serviceable anti-rheumatic and anti-neuralgic that we can have in this class of patients. Chemically it is acetyl salicylic acid forming crystals soluble in alcohol and insoluble in water. Its taste is acid and not disagreeable. It remains unchanged in the stomach, giving rise to no irritation but the alkaline media of the intestines; salicylic acid is gradually liberated in the nascent state and its absorption is probably responsible for the efficiency of the drug. Its prompt elimination is readily accounted for by the profuse sweats and increased action of the kidneys with the fall in temperature.

84. **Veratrum Viride.**—This drug is recommended by Stephens in the treatment of pneumonia. Out of 54 cases thus treated he had 50 recoveries. The 4 necessarily fatal cases were in patients of advanced age and under unfavorable constitutional conditions. The preparation that he uses is the Norwood tincture which is most uniform in its action. The veratrum treatment of pneumonia does not require any intricate formula. The medicine can be reduced infinitesimally and given with precision. The reduction of blood pressure should be made gradual and not in excess. Veratrum is contra-indicated in fatty degeneration of the heart, gastritis and peritonitis. He says that we are not often called to see a case of pneumonia during the rigor or algid stage, but usually in the stage of fever. If the patient is seen during the subjective symptoms and the temperature is appreciably elevated during the algid stage, the treatment may commence and the duration of the attack be aborted. He prescribes veratrum with the compound syrup of squills or syrup of tolu and wine of ipecac in the proportion of one to two of the latter, giving ten drops for the beginning dose and increasing as required.

85. **Appendicitis.**—The salient points summarized by Mitchell are as follows: "1. It seems fairly clear that appendicitis should be usually treated as a medical disease, unless suppuration, gangrene, or perforation occur. 2. We are never justified in advising an operation while the appendix is inflamed, just to prevent complications. 3. If accurate diagnosis and skilful medical treatment were applied in every case, these complications would be infrequent and the death-rate greatly diminished. 4. In recurrent appendicitis it is our duty to advise removal of the appendix between attacks. 5. Imagine yourself in your patient's place, and treat him as you would wish to be treated yourself."

86. **Conjunctivitis from Caterpillar Hairs.**—The first account of this cause of ophthalmia was given by Pagenstecher in 1883. Other observers, especially from the Bonn Clinic, have since reported more cases. Natanson is apparently the only previous non-German observer of this cause of conjunctivitis. Denig, after a few remarks, reports a case observed by him in New York. The species of caterpillar was defined by him as that of the "tussock moth," Orgyia pudibunda, but other species are also dangerous, especially what he calls the "procession caterpillar," "bramble caterpillar" and the "Keiferspinner." In the case described there was slight blepharospasm and reddened and swollen conjunctiva of the under lids. The whole extent of the inflamed tissue of the inner lid and the conjunctiva and the connective tissue were strewn with small blackish hairs, which appeared to be encapsuled in small bullæ. These blebs varied from day to day and sometimes were large enough to be seen with the unaided eye. Similar nodular swellings have also been observed in the iris by penetration of the cornea. The inflammation due to this cause is a tedious one, on account of locality a dangerous one, and there is the possibility of hairs getting on the mucous membrane of the throat and respiratory apparatus. As regards therapy he would warn against wiping the eyes, and after cocainization he washes out the eye with an indifferent sterilizing fluid so as to get rid of the larger number of hairs; little bundles can be removed with pincers. A salve should be employed later and cocain applied to relieve the pain.

91. **Peritoneal Tuberculosis.**—Neff offers the following conclusions as a result of a discussion of the literature and a consideration of the subject: "1. Tubercular peritonitis is a surgical disease, and should be treated surgically, not medically, for the simple reason that when treated medically patients die, but when treated surgically a cure is effected in a large proportion of cases, and a marked improvement follows in all. 2. The proper treatment is abdominal section rapidly and carefully performed. 3. Danger from operation is very slight, the mortality being less than 3 per cent. 4. Of the many theories advanced to account for the cure in these cases, the antitoxin theory of Gatti seems to be the most rational. It is not unlikely, however, that the good results attained are due to a combination of several of the various causes assigned. 5. Sepsis is not apt to occur on account of the pathological changes that have taken place in the peritoneum. 6. Tuberculous infection of the wound does not occur. 7. Antiseptics are useless, and drainage should not be employed if it can be avoided, as it is apt to leave a permanent fistula. 8. Most of the deaths after the operation have been due to a general tuberculosis or tuberculosis of some other organ. 9. The successful treatment of this disease depends upon the diagnostic ability, good judgment, technic and skill of the man behind the knife."

97. **Malaria.**—Krauss describes a special form of malarial infection in which he has examined the blood and which shows special symptoms and peculiarities. As opposed to typical malaria, we have a remittent type of fever, a rather indefinite tongue which may be dry and red like typhoid, or white, broad and flabby. In the latter case we have the parasite within the red corpuscles if examination is made at the proper time. The fever is simple and refractory to quinin. It differs from typhoid in the quick invasion, early prostration, sweaty skin, absence of bowel symptoms and eruption, failure to immunize, non-fatality, absence of Widal reaction, hunger instead of anorexia and clear intelligence even in the severest stages. The blood findings are distinct. There is a marked leucocytosis often for days after the suspension of quinin, and the presence of a great number of so-called dust granules. These at first were thought to be embryons, but are too large and behave more like protoplastic substance of the polyleucocyte when we use the polychrome stain. Krauss called attention to these bodies and their relation to the indefinite malarias, about eight years ago, calling them extra-corpuscular parasites on account of the similarity of their staining reaction to that of malarial plasmodia. Shortly after, Müller's hematokonea, which are quite similar to these, appeared in the literature. Krauss suggests the possibility of these continued fevers having a pathology giving the same blood changes to those found in cachexia, and secondly, the similarity with sepsis as to the clinical history of leucocytosis. This fever has been spoken of as a septic fever by Witherspoon, Preble and others. He has satisfied himself that given a case with dry red tongue and the group of symptoms mentioned, very few if any plasmodia will be found and quinin can do no good. That it depends on malarial infection seems hard to dispute; it occurs principally in the early autumn, and when repeated more or less latent malarial infection is apt to have taken place. How sepsis can follow purely malarial infection is not clear. It seems to be a matter of autosepsis due to the possible toxins in the body.

123.—**Impoverished Blood.**—The condition of the blood as a cause of insanity is insisted upon by Wherry, who tabulates the averages of examinations of 324 cases including various forms of mental disease which were taken in the order of their admission, and not selected.

139. **Pneumonia.**—Bartle offers his opinion as to the value of bicarbonate of potassium in the early stages of pneumonia, that is, not depending on it exclusively, but in combination with strychnia and proper dietetic treatment and with care as to the bowels. He reports cases in which he found giving .8 gram of bicarbonate in capsules every four hours of value. The result of the treatment is that pneumonia is apparently aborted; the drug relieves congestion by dilating the peripheral vessels, as he holds, and reduces the temperature by alkalinizing the blood. After the stage of consolidation sets in, he does not consider it of much use, but in the first few hours of the disease it has proven to be of great value.

Two Cases of Post-Operative Thrombosis of the Mesenteric Vessels Followed by Death. A. Ernest Maylard.—The author reports two cases, both in females of similar age, in which there was a thrombosis of the mesenteric vessels occurring after an operation; one a case of gastric jejunostomy and the other of excision of one-half of the thyroid gland. The symptoms are discussed and the diagnostic points especially noted. Maylard thinks that the following symptoms occurring within a few days after operation may be taken as suggesting post-operative thrombosis of the mesenteric vessels, and all the more so when the operation is not one involving the intestines. "1. The onset of intra-abdominal pain, gradual or acute, but more or less constant, and possibly of a colicky character. 2. Neither tenderness on palpation of the abdomen, nor distension nor rigidity of the parietes in the earlier stages. 3. Possibly diarrhea with or without blood. 4. Possibly vomiting, but not of the usually acute obstructive character. 5. Rapidity of pulse. 6. Undue and inexplicable restlessness and excitability. 7. Any pre-existing symptoms of cardiac or vascular disease may be considered to attach additional weight to the significance of the other symptoms." He remarks that in searching the literature he has found no record of cases of thrombosis of the mesenteric veins following or dependent on operation.

Removal of Great Lengths of Intestine. Alexander Blayney.—A case in which 8 ft. 4 in. of the ileum were resected is reported and the literature of similar operations reviewed. Several American cases are not included. The most striking feature of the subsequent history of the cases that survived is that whereas some showed symptoms of intestinal disturbance, especially in a tendency to diarrhea, in the one where the greatest length of intestine was removed (Ruggi's) these symptoms were absent. In seven cases which showed subsequent disturbance the length of the intestine removed was over 200 c.c., with two exceptions, one of these being a case of contracted kidney, and in 14 surviving cases, which showed no intestinal disturbance, the length of the intestine removed was under 200 c.c. with one exception and in this case it only exceeded about two inches. Therefore, 200 c.c. seems to be about the danger limit as regards this particular disturbance. Children must be considered as not like adults in this respect, as in Ruggi's case the patient was only a little over 8 years of age. The explanation suggested is that as in animals where no intestinal trouble follows intestinal resection marked hypertrophy of the intestine was found to have taken place; it is easy, therefore, to suppose that such a hypertrophy will occur in undeveloped children sooner than in adults, or possibly Ruggi's case had an abnormally long intestine. If we accept Treves' measurements of 22 ft. 5 in. as the total length of the small intestine and take 200 cm. or 6 ft. 6.5 in. from this, we find that somewhat less than one-third is the limit beyond which we can not safely go in removal, and thus Senn is the most accurate of experimenters as regards his deduction in reference to man, for it was he who asserted that resection of over one-third of the small intestine was likely to be accompanied by strong digestive disturbances probably terminating in death.

After-Care of Cases Operated on for Perforation of the Stomach.—The operation for gastric perforation is like that for strangulated hernia, one for which every physician must be prepared to operate in emergencies; hence, arises the importance of knowledge of its after-treatment. The main questions are those relating to food, position occupied by the patient and aperients. As to food it must be of almost a necessity liquid and such as to require no gastric digestion. For twenty-four hours nothing but water or water containing some substance which is not a food, such as perhaps a little addition to the water in the way of carminatives, a little chloroform water or a little very weak tea without sugar or milk. He thinks milk is probably one of the worst things to be given to invalids. It contains proteids and therefore undergoes digestion in the stomach. This holds good whether it is buttermilk or koumiss. Aerated drinks have moreover the possible objection that the gas may force its way through the wound; though there is little cause to fear this, it is best to be on the safe side. The food should not be too stimulating; meat extracts are therefore inadvisable. Alcoholic drinks are also contra-indicated. The food that best meets the requirements of these cases is in Gilford's opinion grape sugar combined with some flavor. Raisin tea, made by pouring boiling water on one-half its bulk in chopped raisins, stewed for one-half hour and filtered, and next to this decoction of malt; though when given too freely this may produce diarrhea. After these in from one to three days a mixture of cream and water is added to the list and these three preparations may be continued until the end of the first week or longer. Generally, however, he adds a little starchy food to the cream, but such as contains not more than a trace of proteid. It is probable that fresh wounds of the stomach heal as quickly as do those of the face, but it is best not to assume that union is complete until the end of the first week. At the end of the week if the patient has done well solid food may be commenced, such as lunch crackers well chewed and sometimes a little bit of scraped fat from cold soft pork. After a few days the diet is still further varied, but still keeping in mind the foods which undergo intestinal rather than stomach digestion. Repeated rises of temperature and tenderness over the region of the stomach must be regarded as warning for precaution in feeding. The appetite then becomes the safest criterion. The position of the patient should be regulated by physiologic requirements and the position of the ulcer. The supine position on the back is not a good one; as the natural position is more or less on the right side, it is well that the head and shoulders should be well raised. In case of ulcers on the posterior surface the patient should be first placed well over on the right side, and should afterwards assume the sitting-up position or the shoulders be raised and the patient turned slightly to the right. Where the ulcer is low down on the anterior wall it may be then best for the patient to be lying on his back. In the case of ulcers of the lesser curvature the higher the patient can sit up with comfort the better. The passage of liquids over the wound may not be so harmful and may often be an advantage. Plain hot water, peppermint water, or water with a very little carbolic acid added may even be good. Nothing requires more judgment than the use of aperients, and it is well to refrain from irritating the stomach by aperients where there has been a limited peritonitis. Aperient enemas may be used twenty-four hours after operation and repeated if relief is obtained. In some cases where there is no peritonitis and the lower part of the abdomen is out of order it may be necessary to use drugs; of these magnesium sulphate and calomel are probably the best.

Improved Incision in Laparotomy for Prevention of Post-Operative Hernia. Arthur H. Buck.—The causes of

post-operative hernia are first noticed, and the author concludes that division of an aponeurosis without supporting muscle is bad, and the division of the muscle in the direction of the fibers can not be satisfactory if it involves division of the motor nerve fibers unless supported by other uninjured muscle or aponeurosis. He therefore operates by dividing the anterior layer of the sheath of the rectus an inch or more from the inner edge of the muscle, upwards and downwards to the same extent as the skin incision, taking care not to injure the muscle fibers themselves; then enucleation of the muscle from the sheath outwards, division of the posterior sheath, together with transversalis fascia, subperitoneal fat and the peritoneum. As soon as the peritoneum had been incised, the forefinger was introduced and the following structures divided up and down as far as necessary; in the whole length of the incision, the transversalis fascia, subperitoneal fat and peritoneum, and above the level of the fold of Douglas the posterior layers of the muscle sheath. To close the abdomen the above structures can be readily united by a continuous suture, the necessary parts being retracted to help the operator. The rectus is allowed to slide back in its natural position, thereby completely covering the line of suture. The anterior layers of the sheath are united by a similar continuous suture. The suprapubic wound is closed in the usual way. The advantages of this method he thinks are the simplicity, the involvement in the incision of only aponeurotic structures afterwards supported by a strong uninjured muscle, no division of nerves, the improbability of hernia and the great reduction in the period of convalescence.

Journal of Tropical Medicine, November 1.

Beri-Beri and the Heart. Arthur Stanley.—The action of beri-beri on the heart is stated by Stanley, who sums up his conclusions as follows: 1. Beri-beri has a marked degenerative action on the heart muscle, which frequently causes fatal circulatory failure. 2. In this respect beri-beri resembles other toxemic diseases, such as diphtheria, influenza, and alcohol and arsenic poisoning, which often causes peripheral neuritis, and also other toxemic diseases, such as typhoid fever, plague, and acute rheumatism, which do not or rarely give rise to peripheral neuritis. 3. Beri-beri and diphtheria are the diseases par excellence in which sudden fatal heart failure occurs. 4. The heart muscle degeneration is not a secondary result of neuritis of the vagus. 5. The heart muscle degeneration takes place as a rule before skeletal muscle degeneration, and is the result probably of direct action of the toxin, and not a secondary result of nerve change. 6. Sudden heart-failure does not indicate a sudden lesion, but rather is the result of a gradually-increasing heart weakness from cardiac muscle degeneration, which may be precipitated by any sudden exertion, but more frequently is the result of the principle of "all or nothing"—the transition from "all" to nothing being necessarily rapid. 7. The cardiac physical signs in beri-beri closely resemble those found in diphtheria, and are of paramount importance in prognosis and treatment.

The Lancet, November 16.

Impressions About Chloroform and Ether. William Mitchell Banks.—The author disbelieves in the value of the Hyderabad Commission reports and asks what benefit has been derived from these liberal experiments on dogs and the details that they involve. Indeed, he can not see where experiments on animals has helped us in this matter, but he hopes that no lying antivivisectionist will misconstrue his meaning, for though the experiments did not help, he is glad they have been done to relieve his mind of thinking something was left undone. No charge of cruelty can be made, as the animals simply passed away without pain. The simple and all important keynote is plenty of air and plenty of anesthesia. The speculation as to whether death comes from the heart or lungs by chloroform is not important. We know that chloroform is infinitely the more dangerous in animals, and to a certain point is a depressant as ether is a stimulant. In order to have the student grasp the difference between the action of these two he speaks of their victims as the white man and the blue man. The white man is being poisoned by chloroform and is always in a dangerous way. His heart is working very feebly and at any moment may give out. The blue man ought not to have been allowed to become blue, but still he is not in such straits as the other. If he can get a little air into his lungs it would be very hard to kill him. In his own experience he has only had two deaths, both from chloroform, but the number of hair-breadth escapes is fearful to consider. In the majority of cases, however, the man dying from chloroform does not suddenly collapse; he has been in a dangerous way for some time before, and the anesthetist had not been able to recognize the early signs of danger and avert it in time. There is a kind of anesthetist who drains out his chloroform by the drop and keeps the surgeon in constant hot water, and by the time the anesthesia has been attained the patient has inhaled a large amount of the anesthetic and goes deeply under. There is another kind who seems utterly unaware that he is dealing with a poison that will kill of itself if only enough be given. Some patients take their chloroform very quietly with a somewhat shallow breathing and the anesthetist does not see when the patient is completely under so that he can stop his anesthetic. The great secret is to keep the patient on the balance, just on the point of coming out. It does not matter if he does cry out occasionally, he will not remember anything about it afterwards. Another important matter is the ability of the anesthetist sometimes to recognize whether the patient is breathing fully and freely or only getting into his lungs air filled with chloroform. He can not see the contra-indication of the tongue forceps; if there is any safety by holding the tongue, a little discomfort lasting a few hours afterwards should not be considered. The dangerous time in giving chloroform is the struggling period. Let the patient get a few good gasps of air when taking the anesthetic in these cases and then administer the anesthetic, taking care to follow the movements of the head and he will probably sink quietly and safely back on his pillow. The great dangers of chloroform are: 1. Absolute overdosing of the patient up to the poisoning point when there is no necessity of it. 2. An omission to allow the patient to be constantly and freely getting abundance of air into his lungs. 3. Violent repression during the stage of excitement, combined with the continued dosing of chloroform. A good chloroformist should rapidly appreciate the leading characteristics of his patient and act accordingly. The slightest shade of pallor should be noted and the patient at once revived. The danger is greatest between six and ten minutes from the time the anesthetic is commenced. The anesthetist's eyes should not be taken off the patient's face for a minute; upon the slightest difficulty in breathing the tongue should be instantly brought out. With regard to ether the great point is to keep the larynx free from frothy sticky mucus. The jaws should be forced open with a gag and the mucus swabbed out. Two difficulties about ether are: 1, it is not so easy to take or so easy to give as chloroform, but it ought to be more often used, and 2, as the author says, that in special operations, especially in those of the anus and urethra, it seems impossible to get the muscular action subdued in certain people by ether. In these, chloroform is indicated and is required in the full amount. More people are sick under ether, but when a bad sickness lasting for a long time occurs, chloroform is the cause. Ice and small mustard poultices over the epigastrium seem to do as much good as anything else. In reviving collapsed patients there is but little use in electricity; artificial respiration should be resorted to, and Banks is sure that he has seen good from the subcutaneous injection of ether and strychnia. In ether suffocation, mop out the mucus and not leave the head hang down, but quite the reverse. Failing with other methods he would open the larynx, blow air into the lungs while also using the Sylvester method. There is a small and very simple trick which is an effective means of rousing up a patient from a weak fainting condition if used sufficiently early, namely, rubbing his nose and lips vigorously up and down with a rough

towel, which some of his pupils have come to call a "dry shave." He saw a clever anesthetist keep a most feeble woman safe through a prolonged operation by continuously bringing her to the surface by this means, never allowing her to get faint. As regards administration, he believes in a little stimulant sometimes before anesthetization and insists on absolute silence, and after he has everything quiet he tells the patient to count with him up to 100, beginning to count slowly and then singing the numbers in a drawling tone and then a sort of chant. This seems to lull the patient to sleep. No bronchitic or asthmatic subject should be given ether, and he thinks chloroform the best anesthetic for old people. He always examines the patient's heart before operation, but it is really of no great value, as the real danger comes from dilatation or fatty degeneration, which can not be discovered by the usual perfunctory examination. Valvular disease need not be taken into account. The presence of albumin and sugar in the urine is a matter of importance, not often looked for. If it exists the patient should be treated with the smallest possible amount of anesthesia, and, if possible, local anesthesia used. As regards the safest position, he thinks there is no doubt that the recumbent position on the right side is the best, the upright position the worst; he attributes to this the safety of chloroform in obstetrics. Coroners' inquests with their publication of distressing deaths during anesthesia have caused many deaths in nervous patients. He wishes they could be dispensed with. In conclusion he remarks on the necessity of the teaching of anesthesia, which every student ought to have instead of so much useless biology, anatomy, physiology and materia medica, and a skilled anesthetist in the hospitals attached to the medical school should be the one to teach the students.

Bulletin Medical (Paris), October 5.

The Seashore in Local Tuberculosis in Children. Poisson.—In his address on the Conservative Treatment of Local Tuberculosis, prepared by request for the recent French triennial congress of gynecology and pediatrics, Poisson remarked that when a child is only lightly affected with tuberculosis it recovers spontaneously if taken to the seashore. When local treatment is necessary the seashore is the indispensable adjuvant, and when surgical intervention is required, sea air is the best of all treatment as a preliminary and sequel to the operation. When tuberculosis is certain or merely suspected, the child should be taken to the seashore as soon as possible, and arrangements should be made for a protracted sojourn, long after recovery. Hydrotherapy is useful as a general measure, especially baths of mother-water for glandular affections. Injections of iodoformed ether in case of a suppurating lesion, not communicating with the outer air, will prevent the spontaneous opening of the lesion and dry up the suppuration at its source. About 10 to 20 gm. of 5 per cent. iodoformed ether are sufficient. Camphorated naphthol should be used with great caution. The amount injected should never surpass 1 gm. A good formula is 5 gm. of beta-naphthol and of camphor to 100 gm. of warm distilled and alcoholized water. Ambulatory treatment of the surgical cases is liable to entail a vicious attitude and does not prevent ankylosis. The sclerogenic method of treatment has proved very successful in many cases, especially when preceded by several weeks of immobilization. It is particularly valuable in torpid arthritis and osteo-arthritis. Comby stated that he had witnessed a number of complete cures under the influence of sea air, including the peritoneal and pleuro-peritoneal varieties. Some persons believe that sea air has a tendency to increase the frequency of meningitis, but the statistics at the Pem-Bron sanitarium show no more than the average proportion. Hallopeau reported the prompt cure of ten children with cutaneous or ganglionary tubercular manifestations by the application of potassium permanganate, either in a 50 per cent. solution or in powdered form after scarification.

Osteomyelitis in the Newly-Born. L. D'Astros.—In the majority of the eleven cases of osteomyelitis in new-born infants which d'Astros has observed, the femur was the site of the lesion. In several, the lesions were multiple. In one case intra-uterine infection was evident; in 4 spontaneous recovery occurred without suppuration; in one suppuration was observed in one bone but not in the others affected. The lesion assumed a chronic character in 2, one child dying a few months later with pneumonia which had been preceded by spasm of the glottis recurring five to ten times a day for four months. The other chronic case healed after curetting the focus, but rachitis developed later, probably due to the disturbance in the bone marrow due to the early lesion.

October 9.

Diagnosis by Means of the Blood. E. Calmette.—Review of all the works on the subject published this year.

Treatment of Eclampsia.—Pinard states that he has seen fatal cases of puerperal eclampsia run their course without a trace of albuminuria. Tarnier said in 1873 that no woman on a milk diet ever has eclampsia, and Pinard's experience fully confirms this view. He has never witnessed any benefit from lavage of the blood. The issue of the eclampsia depends upon the condition of the patient's liver. When eclampsia develops, the noble elements of the liver are destroyed and the resulting hepato-toxemia is not influenced by any obstetric intervention, which is more dangerous than it is useful. Dilatation is especially difficult, owing to the tetanic contractions. The infants born of mothers in eclampsia are degenerates, with incontinence of urine, umbilical hernia, etc., and either die soon or are weaklings. Ollive, on the other hand, proclaims that he has invariably witnessed the disappearance of the eclamptic seizures after venesection followed by transfusion of salt solution, the so-called "lavage of the blood."

Abnormal Presentation a Sign of Degeneracy. R. Larger.—An abnormal position in the uterus is the result of the abnormal movements of a degenerate fetus. An abnormal fetus assumes an abnormal position or has it forced upon him. Experience shows that in families of degenerates the children born in abnormal presentation differ most from the normal standard, during early childhood at least. It is more than probable that they differed from the normal standard also in the intra-uterine life. Larger mentions as instances of abnormal presentation as a sign of degeneracy, the historic cases of Nero, Richard III and Louis XV. Mechanical conditions may favor an abnormal presentation but they are unable to create it alone. Premature birth is likewise a sign of degeneracy, either physical or moral or both, but there are numerous exceptions to this rule.

Thyroid Medication for Children. Ausset.—Besides its remarkable efficacy in myxedema, thyroid treatment has accomplished wonders in infantilism, especially in those cases in which the thyroid function has been impaired in consequence of tuberculosis, rachitis or syphilis. The favorable results of thyroid medication in rachitis indicate that the thyroid gland plays a larger part in its production than has been hitherto credited. The benefits derived from the phosphates in rachitis may be due to the fact that they supply what is lacking in the thyroid gland. Arrested development of the sexual organs is another indication for thyroid treatment, and possibly also sclerodermia, hemophilia, chronic rheumatism and tetany dependent upon some functional disorder in the gland. Children are peculiarly susceptible to intoxication from thyroid medication, and consequently it should always be closely supervised, with especial care in respect to the heart and kidneys, commencing with very small doses and frequently suspending. Manufacturers should state on the label whether the extract is derived from young or adult animals and give the date of its preparation and exact amount of fresh gland represented by each tablet.

October 16.

Influence of Vicissitudes on Evolution of Tuberculosis. Lannelongue.—Animals submitted to moderate cold and slight variations in temperature after inoculation with tuberculosis did not show any difference in the course of the disease. But abrupt and marked changes in temperature, which had no effect on healthy animals, accelerated the course of the tuberculosis in a remarkable degree. The guinea-pigs in some

of the tests were kept at 38 C. for nine hours and then placed out of doors during spring and summer weather.

Cacodylic Medication in Bronchitis with Asthma. P. GALLOIS.—Fifteen elderly patients with chronic bronchitis accompanied by severe asthma, were remarkably relieved and improved by cacodylic medication. Gallois gave 0.1 gm. of sodium cacodylate three times a day in rum, syrup and water, flavored with peppermint.

Bulletin de la Soc. Med. des Hop. de Paris, October 24.

Toxic Polyneuritis. M. SOUPAULT.—Three women employed in a dye-house in cleaning gloves became affected with a typical, peripheral polyneuritis. Their work consisted in keeping the gloves immersed in the cleansing fluid with one hand while they scrubbed them with the other. The fluid seemed to be a mixture of petroleum ether, gasoline and benzine. A few instances of intoxication from the use of benzine have been recorded, but nothing of the kind has been published in regard to petroleum or its compounds. The benzine used in rubber factories is liable to affect the workers in it. After half an hour they become excited and gay; this is succeeded by a period of depression and finally the subject falls an inert mass. She revives after being carried into the fresh air and rubbed with alcohol. The intoxication subsides in about fifteen minutes and nothing but a severe headache remains. After the first time the workers gradually become accustomed to the benzine as a rule, and remain in the same occupation for seven to eleven years and more. Occasionally an employe has to abandon the work entirely. These accidents are less severe, the purer the benzine that is used, but the large establishments have a special service organized for the care of workwomen thus affected.

Treatment of Syphilitic Myelitis by Intraspinal Injection of Mercury. SCHACHMANN.—In the writer's experience at Bucharest he noticed that cutaneous syphilitic lesions healed more rapidly when in immediate contact with the mercurial application, under a Vigo plaster for instance, than elsewhere, during the course of general mercurial treatment. He conceived the idea that syphilitic lesions of the spinal cord might be favorably influenced by intraspinal injection of the solution of mercury. He reports four cases thus treated, one in detail. This was an old syphilitic with severe primary and secondary manifestations which yielded to mercurial treatment. Later, symptoms of myelitis developed and in spite of vigorous mercurial treatment the patient, a man of 29, was unable to walk without assistance on both sides, knee-jerk exaggerated, spinal trepidation extremely intense, predominating on the left side and causing inability to stand. This was the condition after 30 injections of mercury benzoate, which cured the lumbar and girdle pains but had no effect on the myelitis. He was treated then by injection of 1 c.c. of a 1 per cent. solution of mercury benzoate, the needle inserted into the opening in the last sacral vertebra. The needle was connected with a double bulb which allowed the aspiration of a corresponding amount of cerebrospinal fluid immediately preceding the injection of the mercurial fluid and without removing the needle. After twenty-three of these epidural injections in the course of twenty-five days the patient is able to get out of bed and walk up and down the room alone, erect, without looking at his feet, without much fatigue, always ready to recommence; appetite good; he sleeps sound, has no pain; the sphincters function normally; reflexes normal and very slight trepidation. This improvement could be traced day by day. The first injections caused restlessness, slight rise of temperature and insomnia, but these by-effects had all completely subsided by the fifth injection. They were never severe and consequently Schachmann considers them trifling and that this epidural mercurialization of spinal syphilitic lesions which do not yield to treatment by other measures, is a harmless and most effective method. He suggests that it might prove useful in case of non-syphilitic lesions. Jaboulay has reported a case of syphilitic myelitis which he treated by injecting quite a large amount of potassium iodid into the subarachnoid space. The patient died. Jacob of Leyden's clinic has also reported three similar cases with one improvement. Toulouse found that reducing the amount of salt in the food enhanced the action of potassium iodid in a case of cutaneous syphilitic lesions, resulting in the prompt cure of the hitherto rebellious lesions, but the coincident symptoms of general paralysis were not affected by even this magnified action of the specific treatment.

Bulletin de la Soc. de Pharmacie de Bordeaux, August.

New Method of Integral Destruction of Organic Matters. G. DENIGES.—The oxidizing action of the salts of manganese in a nitric medium has a destructive action on organic matters, and supplemented by the subsequent simultaneous action of sulphuric and nitric acids, will reduce any anatomic specimen in a few hours without the slightest loss of any minerals contained. This method of destruction is peculiarly valuable for forensic research and toxicology in general. It will destroy even the cacodylic molecule. The mixtures are heated in a vessel covered with an inverted glass funnel.

Nord Medical (Lille), November 1.

Intoxication from Thyroid Treatment. G. CARRIÈRE.—Summoned to six different urgent cases of sudden angina pectoris, pulmonary edema or symptoms of acute asystolia, Carrière discovered that each of the patients had been taking thyroid extract to reduce obesity, without the advice of a physician and merely on the recommendation of some druggist or friend. The symptoms in each case were violent and alarming, but the suppression of the thyroid medication banished them completely and permanently.

Progres Medical (Paris), October 26.

Syphilitic Gingivitis Simulating Mercurial Stomatitis. BURET.—Eight and fourteen months after a course of specific treatment, the two syphilitics whose cases are described exhibited a typical gingivitis. The interval had been too long for it to have been due to the preceding mercurial treatment and it was promptly cured by renewal of the treatment, confirming its syphilitic nature.

Revue Hebd. de Laryngologie (Bordeaux), October 26.

Slow Evolution of a Cancer of the Larynx. E. KRAUS.—Schwartz was able to collect 108 cases of cancer of the larynx last spring. The survival averaged two years, and only 2 patients lived for three years and only 1 for four after the tracheotomy required. Kraus removed a tumor in the larynx of a man of 78 which proved to be a lobulated epithelioma of stratified pavement epithelium. It recurred very soon, but under continual administration of Fowler's solution the general health constantly improved and the patient coughed up three pieces of his tumor at different times. The tracheal wound was closed and the patient breathed exclusively through the throat as the remainder of the tumor seemed to shrivel. His voice returned and he was in good health when he died from an intercurrent pneumonia five and one-half years after the tracheotomy. Kraus is inclined to believe that the uninterrupted administration of the arsenic had something to do with the successful resistance of the organism to the epithelioma in this case.

Centralblatt f. d. Grenzgebiete (Jena), October 31.

Relations Between Dupuytren's Contraction and Internal Affections. W. NEUTRA.—In the dozens of works on this subject that have appeared in the last few years some authors describe one thing and others another as Dupuytren's contraction and great uncertainty prevails not only as to the etiology and anatomy but also as to the diagnosis. Trauma seems to be a causal factor only in the predisposed. The disposition is rheumatism or gout according to some opinions, diabetes according to others. A few instances have been reported in which syphilis might have been incriminated. A hereditary predisposition is evidenced by the cases in which Dupuytren's contraction was observed in a family through several generations, although the rheumatic or gouty taint alone may have been the inheritance predisposing to the contracture. Nutritional disturbances from constricting bandages have been noted in certain cases and alcoholism in two. Arteriosclerosis is incrim-

inated by Baehr alone; Anderson considers contraction of the palmar fascia an infectious process. Various kinds of nervous affections have been noted in the etiology, spastic muscular contraction, ulnar neuritis, trophic disturbances due to spinal processes, spastic spinal paralysis, tabes and syringomyelia. The latter has been observed in several cases. The coincidence of the contraction with cerebral affections, progressive paralysis and epilepsy, has also been noted. A number of authors express the opinion that the contraction is the result of trophic disturbances, without specifying the etiology. Similar processes have been observed in horses' feet. Dupuy operated on a horse to cure a contracture of this kind; its recurrence later enhances the resemblance to Dupuytren's contraction. Ledderhose considers it a keloid process, a kind of callus formation. The claw-hand so frequent in syringomyelia is the result of apparently a somewhat similar process, and also the joint affections in tabes and syringomyelia, in which alterations occur in the joint ligaments resembling those in the palmar fascia. Lane and others mention the discovery of similar alterations in the joint ligaments accompanying Dupuytren's contraction.

Deutsche Med. Wochenschrift, November 7.

Differentiation of the Meat of Various Animals by the Biologic Specific Serum Reaction. Uhlenhuth.—The serum of animals previously injected with the specific blood, produces a specific turbidity when added to the serum of the same kind of animal from which the blood was originally derived. This biologic test has proved useful in forensic medicine and Uhlenhuth now proclaims that it is equally effective in differentiating meat from the various animals from which the blood was derived. The research at Loeffler's Institute of Hygiene, which is described in this communication, demonstrated that it was possible by this means to differentiate horse, dog and cat meat, fresh or salted and smoked. Cooking of course coagulates the albumin and renders the test impossible. The dissolving of the meat in water, to make the fluid extract for the tests, can be hastened by adding a little chloroform. The fluid must be filtered perfectly clear.

Functional Test of the Liver. H. Strauss.—Alimentary levulosuria is a valuable means of determining a functional disturbance in the liver as announced in the preceding issue, reviewed last week. It is possible that the reason why levulose behaves so differently from its isomere dextrose, in case of pathological conditions in the liver, may be that the organism has some other means of taking care of dextrose outside of the liver, which is not the case for levulose. Frogs deprived of their livers were still able to elaborate glycogen out of dextrose in Sachs' experiments, while no glycogen was formed when levulose alone was administered. Strauss has collected 49 cases of liver affections in addition to his own series of 50 cases, tested for alimentary dextrosuria. The test was positive in only 2 per cent. In most of the tests of alimentary glycosuria that have been published, cane sugar was used, and the probabilities are that the glycosuria observed was predominantly a levulosuria. In 8 personal tests Strauss noted alimentary levulosuria in 4, dextrosuria in 1 and saccharosuria in 1, with negative results in 2. He does not ascribe a primary importance to the liver affection in the pathogenesis of glycosuria and diabetes. He also believes that we overestimate the primary importance of chronic alcoholism in the pathogenesis of diabetes. Transient acute alcoholism may diminish the tolerance for grape sugar, but chronic alcoholism is unable primarily to effect this.

Endoscopy of the Esophagus and Stomach with Flexible Instruments. Kelling.—Mikulicz demonstrated that it is possible to bring the buccal cavity and the esophagus into a straight line. Kelling utilized this suggestion for endoscopy of these organs by inserting a flexible instrument and inflating the esophagus. He has thus visually inspected the esophagus and stomach in 134 patients and been able to formulate a correct diagnosis, absolutely impossible by any other means, except in the cases of strictures and foreign bodies. He has also been successful in inspecting the abdomen by inserting a Nitze cystoscope through an opening made for the purpose with a trocar, inflating the abdomen with filtered air. Kelling demonstrated on a dog the technique of this procedure at the recent Naturforscher congress. He says that it is painless, harmless, and can be done "ambulant."

The Committee for Cancer Research.—Various veterinarians and professors of anatomy reported at the seventh meeting of this committee that they had never seen nor heard of a cancer on a wild animal. Baelz from Tokio stated that cancer was very rare among the Japanese. It could not be a question of climate, as malignant disease was comparatively frequent among the Europeans and other foreigners residing there. The skin of the Japanese is more resistant; secondary syphilitic exanthemata are extremely rare. When cancer occurs it affects the esophagus most frequently, the stomach next. Instances were related of carcinoma in animals, horses, cattle, cats, pigs, rabbits, rats and mice. A case of carcinoma of the liver in a hen has been reported, and of carcinoma of the ovary in other fowls. Cancer is unknown among cold-blooded animals. Horses as a rule have more innocent tumors than other animals, most frequently sarcoma and melanosarcoma. Schuetz states that he has never seen the latter kind of a tumor in cattle, but round-celled sarcomata are frequent. He suggests the possibility of a single parasite for these various tumors and that it develops differently on different animals. No evidence has been presented to date which excludes the possibility that malignant disease is caused by a single agent.

Muenchener Med. Wochenschrift, November 5.

Tardy Meningitis After Injury to the Skull. K. Fujisawa.—A child of 10 fell from a second story, injuring the left temporal bone with consequent vomiting, convulsions and loss of consciousness, but apparently recovered completely. A year later meningitis developed and at the autopsy an old traumatic encephalitic focus of yellow softening was discovered which had evidently existed without causing symptoms. The base of the brain had been fractured at the time of the traumatism and, over a year later, infection by pyogenic micro-organisms through this fissure, induced the meningitis.

Neuritis Caused by Occupation. L. Hoeflmayer.—A professional neurosis usually develops on a neuropathic basis, but the neuritis in the cases described occurred in robust men, compelled to use the right arm in planing or polishing, etc. It affected the region of the brachial plexus and simulated rheumatism in the shoulder and arm, most severe at night, and induced by certain movements of the arm. Antirheumatic remedies had no effect and there were no signs of myositis. The pains and tenderness on pressure were localized at the points where the nerves involved were accessible. All recovered after treatment by rest, heat and galvanization. Application of leeches to the most sensitive points also proved useful in some cases. Quinin and phenacetin relieved the pains at night and rendered morphin unnecessary. The neuritis was cured in the course of eight or nine weeks, but the patients were advised to seek some other occupation for the following six to twelve months.

Treatment of Osteomalacia by Castration. Eberhart.—Up to the present time no process in the ovary has been discovered typical and specific for osteomalacia, and yet there is evidently some connection between the organ and the disease. Castration has been successful in 83.1 per cent. of the cases in which it has been applied. It should always be preceded by phosphorus treatment, and be considered the last resort. The peculiar pains, the gait and the weakness of the iliac psoas are early signs of the affection. Recurrence has been known as late as seven years after castration.

Diagnosis of Fetal Syphilis. Hecker.—Out of 62 fetuses histologically examined by Hecker, only 26 per cent. proved to be exempt from syphilis and 53 per cent. were unmistakably syphilitic. Nearly half of the latter number had been recognized as syphilitic at the autopsy, but the other 29 per cent. showed no clinical nor anatomic syphilitic manifesta-

tion, and yet the microscope revealed typical syphilitic lesions. The kidney was affected in 90 per cent. of the cases, as disclosed by the microscope. Macroscopically, the spleen and bones were most frequently involved. The kidney is the easiest to examine, as the nuclei take the stain well after maceration, which is not the case with the liver. Cellular infiltration of the smallest cortical arteries is evidently the first stage of interstitial inflammation in these cases. Another certain sign easy to recognize and comparatively frequent, is the infiltration of the larger vessels in the spleen and interstitial inflammation of the thymus. Microscopic examination of the fetus may often prove necessary to determine the existence of syphilis in the family.

Bactericidal Action of Fluorescent Substances. TAPPEINER.—THE JOURNAL has mentioned Raab's discovery that certain fluorescent substances have a marked bactericidal action when exposed to the light, but not in the dark. It seems to be connected in some way with the property of fluorescence. Tappeiner reports further experiments in this line which show that fluorescing acridin and chinolin red, etc., will kill ciliated epithelium from the frog in two-thirds of an hour, while in the dark the epithelium lives for one and one-half to six and one-quarter hours. Frogs were injected with eosin and kept for two to four days in the dark. Fragments of their stained epithelium retained their vitality for more than twenty-four hours in the dark, while they died in a few hours after exposure to the light. Tests with cultures on media that had been mixed with a fluorescent substance, showed that the bacteria flourished when they were kept in the dark but development was arrested when the culture was exposed to the light. Tests with frogs and mice injected with fluorescent substances are now under way and will be reported later. They have already shown that the empty skull of a freshly killed frog allows the passage of the light so as to kill a 1 to 1000 culture of paramecium in a solution of eosin in seventy-five minutes, while similar cultures lived four hours and more when kept in the dark. Glass tubes filled with a 1 to 4000 eosin culture of the paramecium or a 1 to 20,000 acridin culture were introduced under the skin of guinea-pigs exposed to the sun. The paramecium died in one hour under these conditions. The skull of the frog and the skin of the guinea-pig therefore allow the light to pass through them enough to induce fluorescence with its consequent bactericidal action. In all the tests the sunlight was filtered through a solution of copper vitriol to exclude the heat rays.

Wiener Klin. Wochenschrift, November 7.

Remarkable Effect of Electricity in Chloroform Narcosis. S. JELLINEK.—If an electric current of high tension is sent through a rabbit, with the electrodes in the throat and rectum, it is either killed at once, paralyzed or injured in some way so that it does not long survive. Jellinek has found, however, that the effect is different when the rabbit is in chloroform narcosis. It is merely aroused immediately from the profound anesthesia, and no injurious after-effects could be discovered in any of the tests. When the anesthetized rabbit has ceased to respond to external stimuli of any kind, the application of the alternating current for the fraction of a second will revive it and the animal springs up, rolls over and jumps around, with consciousness completely restored. The control animal either dies in the deep narcosis or recovers consciousness after a comparatively long interval. None of the rabbits aroused by the electricity exhibited any pathological symptoms or lesions at any time afterward that could be ascribed to the electricity.

Cataract in Diagnosis of Diabetes. S. KLEIN.—Posterior polar and cortical cataract usually accompanies pigmented retinitis. When it occurs alone and no affection of the choroid can be discovered, it is an invariable sign of some disturbance in the metabolism. In Klein's experience this disturbance has always proved to be diabetes, and he has thus been enabled to diagnose diabetes at an early stage when no other symptoms indicated its existence. The disturbances in the current inside the lens, which are the cause of cataract formation in diabetes, must be quite different in their nature from those causing senile involution and cataract in the absence of a choroid affection or known anomaly in metabolism. Choroid cataract is in itself a complicated cataract and its foundation on some disturbance in the metabolism explains the unfavorable result of attempts to operate in such cases. Of course diabetes may develop later in a person with a senile cataract or vice versa, but posterior polar combined with posterior cortical cataract is characteristic of diabetes.

Acute Iodism Simulating Mumps. K. FUERTH.—Regulation doses of potassium iodid were prescribed for a healthy woman of 52 on account of some eye trouble. After a few weeks a syndrome developed compelling the diagnosis of mumps. It subsided on the suspension of the iodid but recurred a few weeks later with the same fulminating intensity after a single dose.

Grece Medicale (Syra), September.

Discovery of the Tomb of Esculapius. J. SVORONOS.—Twenty years ago the excavations at Epidaurus revealed a very beautiful temple with a subterranean labyrinth with no entrance. Archeologists were unable to determine the purpose of the building nor to whom it had been dedicated if really a temple. The building was distinguished by a dome, but no reference could be found to it in any writings. Svoronos believes that he has solved the mystery and that the structure is the tomb of Esculapius. He has found a coin of Epidaurus with a representation of the temple surmounted by a statue of the goddess Hygeia. Similar subterranean labyrinths found in other temples and in Egypt were always tombs. When heroes were deified the priests kept their burial place a secret, and this probably occurred in the case of Esculapius, who was buried here and the ornate temple was erected to his honor after he had been made a god. These assumptions have been confirmed by Svoronos' recent discovery of a work by Rouphinos, who lived in the fifth century, at a time when Christianity was dispelling the old traditions in regard to mythology. He describes the temple of Esculapius at Epidaurus and mentions the dome and the statue of Hygeia.

Vratch (St. Petersburg), November 2.

Influence of Metals on Blood. ILYASHEFF.—The conclusions of extensive clinical and experimental research are summarized by Ilyasheff in the announcement that salts of the heavy metals, copper, mercury and manganese, administered in small amounts by the mouth, have no appreciable influence on the amount of hemoglobin or on the number of the reds. Salts of iron, however, under the same conditions always have a marked effect in increasing the number of reds and the amount of hemoglobin. It is evident that iron not only stimulates the functions of the blood producing organs, but directly aids in the production of hemoglobin. The influence of the iron is first manifested in the increased number of red corpuscles; the increase in the hemoglobin is a later phenomenon. The eosinophile cells also increase to a remarkable proportion under the influence of iron. This is not observed in animals nor in other conditions in man. The eosin granules contain iron and apparently in a stable organic combination, as they give the iron reaction with ammonium sulphate only after twelve to twenty-four hours.

Cronica Med. Mexicana, November.

Ether to Control the Pain in Burns. B. BELTRAN.—pain of an extensive burn of the second degree vanished in thirty seconds by the clock after the burned part had been wrapped in cotton and enough ether poured on the cotton to thoroughly impregnate it. Even after the ether had all evaporated, the pain did not reappear. This experience was repeated in another case, and Beltran calls attention to this method of permanently relieving the pain in such cases.

Nordiskt Med. Arkiv (Stockholm), October 26.

Defect in the Septum of the Heart. A. JOSEFSON.—A man 24 years of age was brought moribund to the hospital with staphylococcus septicemia. Certain symptoms indicated

ulcerative endocarditis and a mitral defect. At the autopsy an opening 5 by 3.5 cm. in size was found in the septum between the two sides of the heart. The diameter of the lumen of the pulmonary artery was normal. The defect was evidently congenital. The rear mitral valve-flap was slit; Rokitansky noticed a similar slit in 5 out of 24 cases of a defect in the septum. The wall of the right ventricle was remarkably thick but otherwise normal. The patient had never been very strong, but had for years satisfactorily filled a position as gardener, requiring much hard work. He had no rheumatic nor infectious antecedents and the family was healthy. He had never exhibited cyanosis and no one had suspected any heart trouble, although he complained occasionally of shortness of breath. Josefson has been able to find only six cases in the literature of pure septum defect, and in all of these there was some alteration in the pulmonary artery. All were men between 32 and 45. In the rare cases of direct communication between the aorta and the pulmonary artery the patients all die young.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A SYSTEM OF PHYSIOLOGIC THERAPEUTICS. A Practical Exposition of the Methods, Other Than Drug-Giving, Useful in the Prevention of Disease and in the Treatment of the Sick. Edited by Solomon Solis Cohen, A.M., M.D., Professor of Medicine and Therapeutics in the Philadelphia Polyclinic. Volume III—Climatology. Health Resorts. Mineral Springs. By F. Parkes Weber, M.A., M.D., F.R.C.P. (Lond.), Physician to the German Hospital, Dalston; With the Collaboration for America of Guy Hinsdale, A.M., M.D., Secretary of the American Climatological Association, etc. In Two Books. Book I—Principles of Climatotherapy—Ocean Voyages—Mediterranean, European and British Health Resorts. Book II—Mineral Springs. Therapeutics, etc. Illustrated with Maps. Pp. 336-420. Price for the complete set, $22.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

INTERNATIONAL CLINICS. A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattell, A.M., M.D. Philadelphia; John B. Murphy, M.D., Chicago; Alexander D. Blackader, M.D., Montreal; H. C. Wood, M.D., Philadelphia; T. M. Rotch, M.D., Boston; E. Landolt, M.D., Paris; Thomas G. Morton, M.D., Philadelphia; Charles H. Reed, M.D., Philadelphia; J. W. Ballantyne, M.D., Edinburgh, and John Harold, M.D., London. Volume III. Eleventh Series, 1901. Cloth. Pp. 303. Price, $2.00. Philadelphia: J. B. Lippincott Co. 1901.

ATLAS AND PRINCIPLES OF BACTERIOLOGY and Text-Book of Special Bacteriologic Diagnosis. By Prof. Dr. K. B. Lehmann, Director of the Hygienic Institute in Wurzburg, and R. O. Neumann, Dr. Phil. and Med., Assistant in the Hygienic Institute in Wurzburg. Authorized Translation from the Second Enlarged and Revised German Edition. Edited by George H. Weaver, M.D., Assistant Professor of Pathology, Rush Medical College, Chicago. Parts I and II. With 632 Figures on 69 Lithographic Plates. Cloth. Pp. 511. Price, $2.50 per volume. Philadelphia and London: W. B. Saunders & Co. 1901.

DISEASES OF THE INTESTINES. Their Special Pathology, Diagnosis and Treatment, with Sections on Anatomy and Physiology, Microscopic and Chemic Examination of the Intestinal Contents, Secretion, Feces, and Urine, Intestinal Bacteria and Parasites; Surgery of the Intestines; Dietetics, Diseases of the Rectum, etc. By John C. Hemmeter, M.D., Ph.D., Professor in the Medical Department of the University of Maryland. In Two Volumes. Vol. I. With Many Illustrations, Some of Which Are in Colors. Cloth. Pp. 742. Price, $5.00. Philadelphia: P. Blakiston's Son & Co. 1901.
